Frodsham's experiments on suspending springs are also noticed under HOROLOGY. In no case does Mr. Frodsham seem to have found a spring which caused the clock to *gain* in the larger arcs, which, on the information of other makers, and on theoretical grounds, we consider possible. With a spring stiffer than that which was isochronous, Mr. Frodsham found that using as effective lengths 0·97, 0·66, and 0·50 of an inch, the change of rate produced by using 4lb. 1oz. as the weight, instead of 2lb. 2oz., was to give the clock a losing rate of $3{\cdot}7^{s}$, $2{\cdot}6^{s}$, and $3{\cdot}5^{s}$, respectively. The law is not apparent, and it would seem that, even with this spring, shortening the spring had no sensible effect. Another remark of Mr. Frodsham's, which is very valuable if it be confirmed by extended trials, is, that the spring which produces isochronism is also the spring with which the pendulum, unattached to any clock, will keep up its motion for the longest time. It seems to us probable that this latter quality will belong to the weakest spring which preserves its full elasticity under the pull of the bob; for if the elasticity were perfect, the only cause of loss of motion would be the resistance of the air, which is not sensibly altered by the effect of the spring. However this may be, the subject is well worth further consideration. Notwithstanding the care bestowed by Mr. Frodsham, it is difficult to conduct inquiries of such nicety with an uncompensated pendulum. It will also be necessary, as we shall now point out, to attend to the state of the barometer when the experiments are in progress. For when the effect of the air upon the time of oscillation of a pendulum is examined, it will be found that the *resistance* of the air has no influence except the indirect one of shortening the arc of vibration, that is, of tending to make the clock gain, if the bob move in a circular arc. The *buoyancy* of the air acts more immediately, for it diminishes the *weight* of the pendulum, and leaves the *inertia* unaltered, and therefore diminishes the accelerating force. Hence a greater density in the air acts as a diminution in the force of gravity, that is, makes the clock go slower. The effect is greater indeed than was at one time anticipated; for, as was remarked long ago by Du Buat, and subsequently shown by Bessel, the pendulum must be considered to include in its inertia a small wrapper of air which is involved in it or accompanies it in its course. (See a very elaborate and valuable memoir by Mr. Baily, 'On the Correction of a Pendulum for the Reduction to a Vacuum,' 'Phil. Trans.,' 1832, p. 399.) This latter portion of the effect of the air depends on the form of the pendulum, and possibly may even be affected by the polish of its surface. Now the density of the air is proportional *directly* to the pressure of the atmosphere shown by the barometer, and *inversely* to the temperature, which is known from the thermometer. The latter portion might be practically included in the general compensation for temperature, but the former requires either a specific and peculiar compensation, or may be determined as a residual quantity, and tabulated for each clock with the mean height of the barometer for the period required. Dr. Robinson's investigation on the effect of atmospheric pressure on the rate of a transit clock is referred to under HOROLOGY. The compensation for the variation of atmospheric pressure was made by attaching small barometers to the pendulum rod, but we believe this ingenious idea was not attended with any practical benefit. It would perhaps be possible so to balance some of these contending principles as to obtain a performance nearly perfect; thus an arc of vibration might be selected in which the increased density of the air, by reducing the arc, might accelerate the time of an oscillation as much as the increased buoyancy and inertia would retard it, or so nearly so, that the remaining difference might be completely annihilated by a proper selection of the pendulum spring. But even if this should be effected, and we see no obstacle to it except the time and trouble it would require, any change of the moving power, or of the action of the escapement, would alter the arc and derange the equilibrium. As the effect of time is generally to produce a falling off in the arc, a small addition to the clock weight might be made from time to time, so as to bring back the pendulum to its primitive arc, until the clock is cleaned, and its action restored that way. We shall conclude this long disquisition (which we propose for consideration until decisive experiments are made) by a piece of advice which we can warrant. Where the clock is much exposed to variations of temperature, enclose it in a second covering or closet. This will protect it from injury, and moreover will very much regularise the rude transitions of temperature to which clocks are in this climate liable. It is not improbable that the parts of a clock, and of its pendulum, if much exposed, may take their temperature at different times, and if so, the compensating principle is not brought into action, but must act irregularly.

It has already been said that a clock, to go steadily, should be securely fixed. The common mode is to fasten the case by strong bolts, under the rising board and again about as low as the pendulum bob, to a stone pillar or through a wall. The pendulum is generally suspended from a cock on the back of the frame, but it may be supported on a triangle standing on the rising board, or even from the back of the case, but there is then a fear that the axis of motion may not be in the axis of the pallets, or may not keep so. The clock being fixed, the first step is to put it *into beat*, that is, to make the beats follow at equal intervals. The clock-maker does this in common clocks by bending the crutch, but when the discrepancy is not great, any one may produce the desired equality by tilting the frame a little; in table-clocks there are generally footscrews for the purpose, or if not, the feet may be propped by pieces of wood, card, &c. In astronomical clocks, the angle which the crutch makes with the pallets admits of a small adjustment by two screws, which act on opposite sides of the crutch, and the operation is performed as follows:—Make the beats nearly correct by ear, and by touching the screws: note which screw belongs to the longer leg; then by softly deadening the pendulum as it rises, make it just *not* escape on one side. By very gentle pushes cause it to escape on that side, and see whether it escapes on the other; if it does not, one screw must be screwed up and the other released. After a few trials and errors it will be found that when the pendulum just escapes on either side, it will just escape on the other, and if there be a very small inequality indeed, a little tightening of one of the crutch screws will complete the adjustment. The pendulum should then be brought to rest, and the zero of the plate on which the arc of vibration is read off, be fixed just behind the pointer of the pendulum, shown at C, *figs.* 20, 21, in HOROLOGY. In that article the rule for bringing a clock to time is given.

In an observatory it is always desirable that a clock should have a small losing rate, and be slow rather than fast (the corrections for clock error and clock rate are then additive), so that it would be better to add a smaller weight than 46 grains; and in any case it is more safe to destroy the rate by two operations, especially if the preceding rates were not very carefully determined.

The final adjustment of the compensation can be best accomplished when the clock has gone several months, and when the gain or loss in two of the warmest months in the year is compared with the gain or loss in two of the coldest. Suppose the *mean* temperature in the summer months of trial to be 30° higher than in the winter months, and that the clock loses 1^s more in summer than in winter; it is therefore *under-compensated*, and requires more mercury. Add 1 lb. of mercury, and bring it to a close rate exactly as before; and now let it be *over*-compensated, so that an increase of 24° in the temperature causes it to gain $0^s{\cdot}4$ per day, which, by simple proportion, is the same as a gain of $0^s{\cdot}5$ by 30° of temperature. Hence it is clear that as 1 lb. of mercury causes an alteration of $1^s{\cdot}5$ in the variation due to temperature, if a third of a pound be withdrawn the compensation will be nearly correct. A second trial will perfect the compensation, which should never be afterwards disturbed.

The researches respecting resisting media have already been referred to. There existed for some time a discrepancy between Poisson's factor, by which the correction for buoyancy is to be multiplied, to give the whole effect observed, and Mr. Baily's: the one being 1·5, and the other 1·8. Professor Stokes has reviewed the subject in a memoir published in the 'Transactions of the Cambridge Philosophical Society.' In this inquiry the internal friction of the fluid or medium is taken into account. In the case of a ball-pendulum the resistance is proportional, not to the surface, but to the radius of the sphere, so that the quotient of the resistance divided by the mass increases very rapidly as the radius decreases. Hence the terminal velocity of a minute globule of water, descending through the air, depends almost entirely on the internal friction of air; but since the index of friction is known from Baily's experiments this terminal velocity can be calculated numerically for a globule of given diameter. This velocity is so small in the case of globules, such as those of which clouds are probably formed, that according to Mr. Stokes, the suspension of clouds need not offer any difficulty.

When a pendulum is not limited to one plane, but only to the concave surface of a hollow sphere, we have what is called the *conical* pendulum. Its motions have of late years been investigated in the pages of the 'Philosophical Magazine,' and elsewhere.

Length of Simple and Invariable Pendulum.—The equality of the oscillations of a weight suspended by a line is said to have been used by Ibn Junis, in 1100, and by the Arabian astronomers, for the subdivision of portions of time. (Young, 'Nat. Phil.,' vol. i., p. 595.) This property of the pendulum was remarked by Galileo when a student at Pisa, by observing the vibrations of a lamp swinging from the roof of the cathedral, and was by him proposed as a medical instrument for observations on the pulse. (Drinkwater, 'Life of Galileo,' p. 5.) The simple pendulum was much used as an astronomical instrument (called *perpendiculum* in the older writers) before it was adapted by Huyghens to the clock. Mouton ('Observationes Diametrorum Solis et Lunæ,' Lugd., 1670) applied the vibrations of the simple pendulum successfully to measure the time in which the sun and moon describe their respective diameters, and in the Appendix, p. 427, proposes his *nova mensurarum geometricarum idea*, that is, a decimal system of measures based on the value of a minute in Riccioli's length of a degree. This is his *miliare*, the thousandth part of which he calls a *virga*; and the finds by experiment that the *virga*, which, according to Riccioli, is 5 ft. 4·368 in., Bolognese measure, is the length of a simple pendulum which makes 1252 oscillations in half an hour.

In 1671 Picart was sent to determine the position of Tycho Brahé's observatory at Uranibourg. He took this opportunity of swinging the pendulum, and found the length of the seconds pendulum 3 ft. 0 in. 8$\frac{1}{2}$ l. Paris measure, exactly the same as he had previously found it to be at Paris, and subsequently at Cette, on the south coast of France. Roemer obtained the same result at London, and these erroneous measures of Picart, the first astronomical observer of his day, were for a long time cited as objections to the theory of gravitation.

In 1672 Richer was sent to Cayenne (about 4° 56′ N. lat.) to make a course of observations, and among the rest to observe the length of the seconds pendulum. His words are: "L'une des plus considerables observations que j'ay faites, est celle de la longueur du pendule à secondes de temps, laquelle s'est trouvée plus courte en Caïenne qu'à Paris: car la mesme mesure qui avoit esté marquée en ce lieu-là sur une verge de fer, suivant la longueur qui s'estoit trouvée necessaire pour fair un pendule à secondes de temps, ayant esté apportée en France, et comparée avec celle de Paris, leur difference a esté trouvée d'une ligne et un quart, dont celle de Caïenne est moindre que celle de Paris, laquelle est de 3 pieds 8$\frac{3}{5}$ lignes. Cette observation a esté reiterée pendant dix mois entiers, où il ne s'est point passé de semaine qu'elle n'ait esté faite plusieurs fois avec beaucoup de soin. Les vibrations du pendule simple dont on se servoit, estoient fort petites et duroient fort sensibles jusques à cinquante-deux minutes de temps, et ont esté comparées à celles d'une horloge tres excellente, dont les vibrations marquoient les secondes de temps." ('Recueil des Observations faites en plusieurs Voyages par ordre de sa Majesté,* p. 66, Paris, 1693.) We have cited this passage textually, not only on account of its importance, but because it is generally merely stated that Richer's clock, which was regulated on Paris time, lost more than two minutes at Cayenne. This misrepresents the *evidence* of the experiment, and moreover leaves room to suppose that Richer made a *chance* discovery, whereas the determination of the length of the pendulum was one of the special objects of his mission (see p. 2). Neither Picart nor Richer gives any details of his *modus operandi*.

In 1673 Huyghens published his 'Horologium Oscillatorium,' perhaps the most remarkable mathematico-mechanical work which preceded Newton's 'Principia.' He therein explains the *isochronism* of oscillations in a cycloid, and the mechanical means of making the pendulum swing in a cycloid. He gives theorems for finding the centre of oscillation of several figures, and thence the length of the simple pendulum, corresponding to a compound pendulum of certain forms; and in propositions 19 and 20 (p. 124–5) proves that when the body is the same, the distances of the axes of suspension from the centre of gravity are reciprocally as the distances of the centre of gravity from the respective centres of oscillation, and that the point of suspension and centre of oscillation are convertible. His proposition 25 (p. 151) is on the mode of fixing a universal and perpetual measure, which he proposes should be the third part of a seconds pendulum, and names a *horary foot*.

Newton, in his 'Principia,' lib. i., s. 10, investigates the oscillations of a body in a cycloid, or in any other curve; lib. ii., s. 6, he considers the effects of a resisting medium on a pendulous body; and lib. iii., prop. 19, he determines the figure of the earth, supposing it to be fluid and of uniform density, to be a spheroid of which the equatorial and polar diameters are as 220 : 229. In prop. 20 he computes the lengths of the seconds pendulum and of the degrees of the meridian, which are required on the foregoing suppositions; and he remarks, "Quod inequalitas diametrorum terræ facilius et certius per experimenta pendulorum deprehendi possit quam per arcus geographice mensuratos in meridiano." In the following pages is an analysis of the lengths of the pendulum which had come to his knowledge.

We have not been able to find any account by Graham himself of two very capital improvements which he seems to have introduced into pendulum experiments. The first is a clock, in which "he carefully contrived that its pendulum might at pleasure be reduced to the same length whenever there should be occasion to remove the clock from one place and set it up in another." (Bradley's 'Account of the going of a Clock by Graham, in London, and at Black River, Jamaica,' 'Phil. Trans.,' vol. xxxviii., p. 302.) Probably this was done by drawing the spring through a clip to a given mark; for in another description of a similar clock it is said the suspending spring was broken. We do not, however, see need for any adjustment in this respect, if the spring be pinned into the rod and into its upper axis. The pendulum was not compensated, but a thermometer was enclosed in the clock, and as the rate in different temperatures at the same place had been determined, the reduction to a normal temperature was easy. Clocks of this kind were supplied to the French expeditions for measuring arcs of the meridian in Lapland and Peru. For this latter expedition Graham supplied Godin with a *detached* pendulum, which Godin thus describes:—"Ce pendule est composé en general d'un fil de cuivre, d'une boule de même matière à un de ses bouts, et d'une pièce d'acier taillée en couteau à l'autre bout, qui est celui de suspension: ce couteau porte sur deux montants d'acier en deux points qui designent l'axe du mouvement du pendule." ('Acad. Roy. des Sciences,' 1735, p. 507.) He says its motion was sensible for eighteen hours. It seems that this pendulum, the vibrations of which were to be counted by a clock, was also intended to measure the actual length of the pendulum. Messrs. Bouguer and La Condamine both had detached pendulums made after Graham's idea. Bouguer (same volume, p. 526) describes this pendulum as an invention of his own; La Condamine ('Journal du Voyage,' p. 143) is more open, and says he took the idea from a copy which Hugo made after Graham's. This is almost exactly Kater's invariable pendulum. Mairan's measurement of the length of the seconds pendulum ('Acad. Roy. des Sciences,' 1735, p. 153) is a good specimen of the old method of measuring the length of the pendulum: and the measures of Godin, Bouguer, and La Condamine, in the same volume, are worthy of notice. For references to various pendulum experiments, see Lalande, 'Astronomie,' 3rd edit., s. 2710, *et seq.*

---

* This volume contains Picart's observations, as well as Richer's.

In the first volume of the 'Transactions of the Society of Arts,' p. 238, Mr. Hatton proposed, as a mode of fixing a permanent standard of length, to suspend a weight from a fine hair to a clip in an upright bar, sliding up and down in a vertical frame. The hair passed through a fixed clip. The weight was to be swung, and the vibrations counted, in two positions of the bar, and from the difference in the times of vibration and the space through which the bar was moved, the length of the seconds pendulum was to be computed.

In 1787 Mr. John Whitehurst published 'An attempt towards obtaining invariable Measures of Length,' &c., which is remarkable for its ingenuity. He suspended a leaden ball with a flat steel wire in front of a straight upright frame, the wire being long enough to make forty-two oscillations in a minute. A clock with dead-beat escapement and a clip to hold the wire was slid up and down the frame, and secured and adjustable at two points where the clip made the free oscillations respectively forty-two and eighty-four in a minute. The crutch of the clock, being continued upwards in a screw, carried a weight, by moving which the oscillations of the crutch *alone* could be regulated to forty-two and eighty-four oscillations, and *therefore would not interfere with the free oscillation of the ball and wire, but only keep up their motion.* The going weight of the clock was in each case such as sustained an oscillation of 3°. It is clear that if all were properly executed, the clock-frame with its clip must have been shifted between the two positions through a space equal to the difference between the simple pendulums which correspond to forty-two and eighty-four oscillations per minute. A line was drawn in each position along the upper edge of the clock frame upon a brass rule fixed to the upright support, and this space was afterwards accurately measured, and the length of the simple seconds pendulum thence computed. Whitehurst's length of the seconds pendulum is 39·1196 inches of Troughton's standard, but the corrections for the buoyancy of the air and for temperature are not introduced. It is probable that he introduced greater errors than those he wished to get rid of in Hatton's method, for the real difficulty is not that of counting the vibrations, but of measuring the length between the two clips, in avoiding the errors of temperature, and the uncertainty as to the effective point of suspension. The *principle* of Hatton's method, that of measuring the difference between two pendulums, has been adopted, as we shall see, by Bessel.

The foregoing account is merely a sketch of the history of this mechanical problem, which in the hands of Borda, and more recently of Kater and Bessel, has received a more accurate solution. There are still anomalies and imperfections in some parts of the processes which require clearing up, but the errors have been reduced within comparatively moderate limits. Before describing these experiments we shall give a brief account of the formulæ which they require.

The expression which connects the time of one oscillation of a simple pendulum in an infinitesmal arc, with its length l, at a place where the force of gravity is represented by g, is $t = \pi \frac{l^{\frac{1}{2}}}{g^{\frac{1}{2}}}$, π being 3·141590, or circumference to diameter 1; the measure of gravity g, being twice the space through which a body would fall freely in 1ˢ, or, what is the same thing, the space through which a body would move in 1ˢ, with the velocity which it acquires in falling freely for 1ˢ.

Hence if l be the length of the simple seconds pendulum, $g = \pi^2 l$; therefore g is known when l can be measured. The process therefore of finding the effective force of gravity at any place is reduced to finding the length of the simple pendulum which vibrates seconds.

The French astronomers, in their great survey of the arc of the meridian, determined the *absolute* length of the pendulum at different stations between Dunkerque and Formentera, and also in the continuation to Unst in the Shetland Isles, which is included in the English trigonometrical survey. It is, however, an operation of great delicacy, and when only the *variation* of gravity between different places is required, as is the case in researches into the figure of the earth, the observation may be more easily performed by swinging the *same* pendulum in different places, and ascertaining the number of vibrations which it makes in a day. Thus if n and n' be the number of vibrations made in a day by the *same* pendulum l, at two different places at which the forces of gravity are g and g', and the duration of one vibration at each place be t and t', then since the time of one vibration = a day divided by the number of vibrations, we shall have—

$$\frac{1}{n} : \frac{1}{n'} :: t : t' :: \pi\left(\frac{l}{g}\right)^{\frac{1}{2}} : \pi\left(\frac{l}{g'}\right)^{\frac{1}{2}} :: \frac{1}{g^{\frac{1}{2}}} : \frac{1}{g'^{\frac{1}{2}}},$$

$$\text{or } g : g' :: n^2 : n'^2.$$

That is, the force of gravity varies as the square of the number of vibrations of a given pendulum in the same time, which is usually taken to be a mean solar day. If, therefore, the number of vibrations of a pendulum in one day at a given place, London for instance, be known, and it is then transported to different places, and the number of vibrations in a day counted, a simple proportion will connect the forces of gravity at London and every place at which the observation has been made.

If the length l' of the simple pendulum at any station be required from these observations,

$$\text{since } l : l' :: g : g' :: n^2 : n'^2,$$

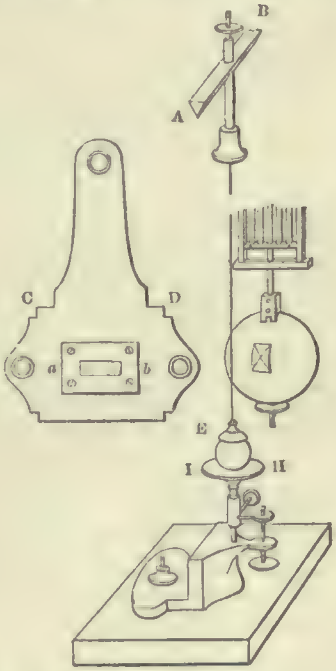
$l' = \frac{l n'^2}{n^2}$, which gives the length of the pendulum at any place in terms of the length at London, and the number of vibrations per diem at that place and London.

Though it scarcely belongs to our subject, we will give the expression by which the ellipticity of the earth is determined from pendulum observations. The length of the seconds pendulum at any latitude, λ, may be supposed $l = \text{A} + \text{B} . \sin.^2 \lambda$, where A and B are constant quantities. Now from all the good observations, either of the actual length or the number of vibrations per day of the same pendulum, determine the values of A and B; then, by Clairaut's theorem,

the ellipticity of the earth = [*] $\cdot 008668 - \frac{\text{B}}{\text{A}}$;

whence the ellipticity is found. By ellipticity is meant the excess of the equatorial over the polar radius of the earth, divided by the polar radius.

The apparatus of Borda will be generally intelligible from the following description and figures.



Borda's Pendulum Apparatus.

The plumb-line is suspended from a knife-edge piece, A B, and is attached below to a cup, E, which is ground to fit very exactly the platinum ball below. A little grease is rubbed on the inside of the cup, making the contact perfect enough to exclude the air and to suspend the ball. The knife-edge rests on agate planes, a, b, which are carefully levelled, and the frame C D, which carries the planes, is fixed immoveably in a horizontal position. The plumb-line is in front of the comparing clock, which has a small cross drawn on the bob. When both are at rest, a telescope having a vertical line in the focus is placed a few feet distant, so that the cross, the plumb-line, and the fixed wire of the telescope are all in the same right line, and all seen *distinctly*.[*] Such a length is given to the plumb-line as that its oscillations shall be a little slower than those of the clock.

---

[*] This is Mr. Airy's value for $\frac{5m}{2}$ where m is the ratio of the centrifugal force at the equator to the force of gravity there. ('Encyclopædia Metropolitana,' Figure of the Earth, sect. 2.) Biot, 'Astronomie,' vol. 3, additions, p. 169, gives 0·00865; the centrifugal force m being supposed $\frac{1}{289}$ of the force of gravity at the equator.

The clock is now set a-going, and when it is quite steady, the platinum ball is drawn a little on one side, and made to swing through a very small arc, one or two degrees at the most. The observer then places himself at the telescope, and notes the exact beat of the clock when the plumb-line bisects the cross and coincides with the fixed wire at the same time: this is called a *coincidence*. As this observation seems much less definite than in Kater's method, it is better to note those beats before and after the coincidence, when the eye cannot distinguish whether it is a coincidence or not, and to take the mean of the two for the true time of coincidence. Immediately after, the extent of the arc through which the plumb-line swings is to be read off on a scale placed just behind it; the thermometers which are near the pendulum must also be read off, and also the height of the barometer. The observer now waits until this appearance presents itself a second time (which may be in about ten minutes, though the interval is quite *ad libitum*), and having thus established the time which elapses between the observations, he may leave the apparatus for three, four, or five hours, when on his return the same observations must be repeated of coincidence, arc, temperature, and barometer, and the series is finished. We should recommend closing as well as commencing a series with two coincidences *in majorem cautelam*, but except as a check, no observations are required except the first and the last. The plumb-line is again set in motion exactly as before, and the second, third, and following series observed. The rate of the clock is established by astronomical observation.

After a satisfactory number of series has been taken, the next object is to measure the length of the pendulum. The plane I H is raised by a fine screw until it just touches the bottom of the platinum ball. This is an operation of great nicety, and must be effected by two or three trials, as the *exact* temperature of the wire at the *exact* moment of contact is required; and the presence of the observer, even for a short time, is sufficient to affect a slight wire very sensibly. Suppose this done, the apparatus is removed or pushed on one side, and a bar, which has a knife-edge above and a sliding tongue below, is suspended in its place. The tongue is slid down until it touches the plane I H, and the distance between the knife-edge and the bottom of the tongue measures the distance between the top and bottom of the pendulum. This distance may be measured in several ways; the French astronomers use a contrivance which need not be described here.

One of the great practical difficulties in this species of pendulum experiments seems to be the extreme and sudden sensibility of the plumb-line to temperature. The whole apparatus is enclosed in a glass cage to exclude currents of air, and the observer is particularly careful, after bringing the lower plane into contact with the bottom of the ball, to absent himself until the temperature is steady, and then to make the contact complete. It is another objection that the different manipulations required are of great delicacy, and therefore not suited to every observer and every place; but when the utmost care and skill are employed, the results appear satisfactory.

The knife-edge, A B, by which the line and ball are suspended, is an ingenious contrivance, exactly similar to Whitehurst's synchronous crutch above described. By the upper screw and weight, the oscillations of the knife-edge *alone* can be made synchronous with the oscillations of the whole pendulum, so that the oscillations are just the same as if the knife-edge were immaterial, and the point of suspension exactly in the line of its edge. The platinum ball can be suspended from any side, and if two positions diametrically opposite be taken, the effect of any irregularity of shape or density disappears from the mean of the two results. There are several corrections to be applied to the quantities immediately given by observation, before the length of the simple pendulum can be concluded. The oscillations are made in an arc of sensible extent. Now the time of oscillation in an arc of A° on each side the lowest point, is greater than the time in an infinitely small arc (which is the arc required), in the proportion of $1+\frac{\sin^2 A^\circ}{16}$ to 1. An expression which depends upon the first and last arcs of each series, gives the correction which is to be added to the number of oscillations observed. This is taken from a table. Between each coincidence, the plumb-line has made two oscillations less than the clock, therefore subtracting twice the number of coincidences from the number of seconds elapsed between the first and last coincidences, you will have the number of oscillations of the pendulum during a certain time shown by the clock. Each of these numbers requires a correction: to the number of oscillations of the pendulum, must be added the correction for arc just mentioned; and to the time as shown by the clock, the proportional part of its rate during the experiment. A simple proportion will now give the number of infinitely small vibrations in 24 hours.

Further corrections are to be applied. The length of the wire and ball during the observations must be reduced to the length they would have had at the temperature when the contact with the plane and the measurement was made, and this again must be converted into the equivalent length when the thermometer is at the freezing-point, which is the French standard temperature. The theoretical pendulum is supposed to swing *in vacuo*, and as the density of the air affects the time of oscillation two ways, both by diminishing the moving force of the pendulum and by adding[*] to its inertia by the air carried along with it, a correction is required on this account, which depends upon the barometer and thermometer, on the specific gravity of the materials of the pendulum, and also on its form.

From the dimensions and specific gravities of the parts of the apparatus, the distance between the centre of oscillation and the bottom of the ball can be computed. Hence the length of the simple pendulum, which oscillates in an infinitely small arc a certain number of times in a day and *in vacuo*, can be assigned, from which the length of the seconds pendulum is deduced by simple proportion.

If the place of observation be above the level of the sea, it is usual to reduce the length to what it would have been at the sea level. This is a very uncertain quantity, as it depends upon the configuration and density of the strata in and near the spot. In the earlier experiments gravity was supposed to vary inversely as the square of the distance from the centre of the earth, and thus the attraction of the matter between the observer and the sea-level was wholly neglected. Dr. Young showed that in a table-land of average density the correction thus obtained was too large, and should be multiplied by 0·66.

For a full description of Borda's method, with instances, &c., see 'Base du Système Métrique Décimal,' vol. iii., p. 337 (Borda's original memoir); and again, vol. iv., p. 441 ('Observations from Formentera to Unst').

Many modifications and improvements have been introduced into Captain Kater's method of determining the length of the pendulum, and we must refer to his paper ('Phil. Trans.,' 1818, p. 33) for a minute description and for a plate of his apparatus.

The principle of his method is founded on the beautiful dynamical theorem due to Huyghens, which we have already mentioned, namely, that the axis of suspension and centre of oscillation are reciprocal in the same body. Now conceive two wedge-formed pieces of steel (knife-edges), with the sharp edges towards each other and parallel, to be fixed at right angles to a bar of any form whatsoever, and in a line passing through its centre of gravity; then if the time of oscillation on either edge be the same, the distance between the knife-edges is the length of the simple pendulum which swings in the same time. Captain Kater, in his experiments, used a pendulum of an inconvenient form, the same nearly as in his invariable pendulum (see cut of Kater's invariable pendulum), with a second knife-edge below the centre of the bob, and there are several doubtful points in the reductions which he employed and the subsequent measurement between the edges; still his memoir must always be carefully perused by any future experimenter who wishes to make himself thoroughly acquainted with the subject. The method of observing the coincidences is remarkably ingenious and accurate.

We conceive that the best form of pendulum for the object of measuring the actual length according to Kater's method is that adopted by Mr. Baily. A C is a rectangular bar, with one knife-edge at the end A, and the other at B, about $\frac{2}{3}$ of the length from the same point. A should be as near the end as sound workmanship will allow. The necessary verifications, namely, the parallelism of the knife-edges, their perpendicularity to the bar, and that the line which joins the knife-edges passes also through the centre of gravity, are all very simple, and there is little difficulty in adjusting the oscillations on each knife-edge to synchronism.[†] This bar pendulum is suspended on agate planes in front of the clock, great care being taken that the support is perfectly firm and the agate planes horizontal. A white disc of a spindle shape and exactly the width of the bar is pasted on the clock bob, and the viewing telescope fixed in a line with the disc and bar, so that, both being at rest, the white disc is just covered by the bar. Captain Kater used a diaphragm in his telescope, the sides of which were parallel to the bar and touched its edges; but it has been found more convenient to place a pair of parallel plates between the bar and the disc, the sides of which are so adjusted as just to allow the disc on the clock bob to be seen between them. There is a divided scale to mark the arc of vibration, two or three thermometers are hung at different heights about the pendulum bar to register the temperature, and there is a barometer for the atmospheric pressure, all which are to be read at the beginning and end of each series. The observation itself is of the simplest kind.

Baily's Convertible Pendulum.

---

[*] This is not always practicable, and it would, generally speaking, be better to place a lens between the cross on the clock-bob and the plumb-line, and to form an image of the cross upon the plumb-line. It is desirable on many accounts that the two pendulums should not be very near each other.

[*] This part of the correction due to the air was omitted in the French experiments and in Captain Kater's: see Mr. Baily's memoir referred to above, and AIR.

[†] This may be done two ways. Place the knife edges A and B at the distance which will give the proper interval for coincidences, 39·4 inches for instance, A being at one end, and make the bar rather more than one-third longer; then the oscillations on B will be slower than those on A. By filing

Set the clock going, and when its arc is steady, give the pendulum a small motion, 1° or 1½° at the utmost. The white disc, which is at first wholly visible, is gradually invaded by the bar, till at last it is entirely covered, first one side and then the other disappearing.* These times of *disappearance* are to be noted. Almost immediately after, the white edges reappear, first on one side and then on the other, and these *reappearances* are noted. The mean of the four gives the true time of coincidence. It has been found convenient in practice not to make the adjustments with the highest degree of precision, for you are then in doubt on which side the first disappearance and reappearance will take place; whereas if there is a very little displacement, attention need only be fixed on every alternate beat, which is less strain on the eye and on the mind. This displacement however must be trifling, otherwise, when the arc becomes small, the disappearances and reappearances will not take place. The reductions for the rate of the clock, for the arc of vibration, the temperature, the buoyancy of the air and its inertia, and the height of the place of observation above the sea-level, are all to be made as in Borda's pendulum. For the details we refer to the standard memoirs which have been published on the subject. But there are two or three points which deserve more attention than they have generally met with. The clock is only to be considered as a counter of the vibrations, and to avoid any error arising from its irregular rate, the observations should be continued without intermission between two epochs, at each of which the error of the clock is ascertained by astronomical observation. If this be done, the only reliance upon the clock is for the short time which elapses between the last coincidence of one series and first of the next. It is true that this mode of observing requires artificial illumination, for it must be continued day and night. This is no disadvantage, but the contrary, for as the other great practical difficulty is that of ascertaining the exact temperature and keeping it steady, the best place for observation is a deep roomy vault or cellar.

The correction for the buoyancy of the air depends on the *specific gravity* of the pendulum; that arising from the dragged air, which we have called inertia, on its *form*. It is very desirable that the experiments should be made *in vacuo*, and where that is difficult or impossible, as in a travelling apparatus, the law and quantity of the correction for each pendulum should have been previously experimentally determined *in vacuo*. The variation for temperature should be got from a comparison of summer and winter experiments at the same place. In addition to the height of the place of observation above the sea-level, a rough survey should be taken of the form of the surrounding country, and of the kind of strata, with the specific gravity of each. This is particularly necessary where the heights are considerable. (See Young's Remarks, 'Phil. Trans.,' 1819, p. 93.)

Still, when every known precaution has been taken, there are anomalies in the results of this experiment which are not yet clearly understood. It is very difficult to make the edge of the knife perfectly straight, and to keep it so when it is fastened to the bar. There is considerable uncertainty in measures of distance between the reciprocal knife-edges; and lastly there is no authorised standard of length at present existing in England in terms of which the distance can be expressed. The length of the simple pendulum which vibrates seconds in the latitude of London, is not at present known with the degree of certainty † which the importance of the problem demands, and which is attainable.

Captain Kater proposed the following form of pendulum for determining the number of oscillations which the same pendulum describes in different places, which is nearly the same as Graham's, above described. Mr. Baily prefers the bar with two knife-edges, the same as that used for determining the absolute length, and he directs observations to be made at each place with both knife-edges. There is certainly a great advantage in having a check upon the knife-edges, as a discrepancy between the two results (supposing the pendulum to have been previously regulated) will show that one of the knife-edges has been injured. To ascertain which of the two it is, requires a second pendulum. Upon the whole, though we prefer Mr. Baily's pendulum to Captain Kater's, yet we think a form suggested by Mr. Airy is, for ordinary purposes, still better—it is, to have the knife-edge placed in that part of the bar where the oscillations take place in the shortest time. In this case it seems probable that any ordinary injury of the knife-edge will not alter the time of vibration. The observer must be very careful in these stiff bars to see that the pendulum is truly vertical, a precaution which in Kater's flexible bar is less necessary. If an observer chooses to have a second knife-edge opposite the former in the pendulum of minimum vibration, there is no objection except the increased resistance of the air, the increased correction for inertia, and the chance of confounding the two positions. The mere observation of the coincidences, which in its present form was first introduced by Kater, is so simple that it will be successfully performed by any person the first time of attempting it, and an error of a second or two in noting the moment is a matter of little importance. There is a far greater latitude for error in noting the temperature and ascertaining the clock-rate, but there is another anomaly attending the knife-edge pendulums, only partially understood at present, which is much more vexatious than temperature or clock-rate. As the pendulum swings about those points of the knife-edge which are in contact with the agate planes, it is clear that, supposing any imperfection in both, these points may be altered, when the axis of suspension, and consequently the time of oscillation, will be altered too. Hence it is advisable to place the knife-edge as exactly as possible always in the same position on the agate plane, both as to front and back, and also as to right and left. It will generally be found that turning the pendulum half round on the same knife-edge will alter its time of vibration sensibly, so that the face in front must always be registered. But even when these precautions are taken, anomalies are still found, which we can only attribute to the following cause:—In most of the pendulums hitherto made the steel knife-edge has been fixed upon a bar of different metal (brass and copper) with stout brass knees, and the two screws which fix the steel knife-edge to the brass knees are at some distance from each other. Now if, from the difference of expansion between the brass knees and the knife-edge, the latter should be curved, not upwards or downwards, but in a horizontal plane, the consequent alteration of time in the oscillation may be very considerable. The steel edge therefore should either be controlled by being ground on a narrow slip let into a brass wedge, or the attaching knees should also be of steel. The uncertainty which appears due to some such cause as that above described may amount to one, two, or even more seconds a day in the invariable pendulum, either of Kater's or Baily's construction. It is evident that in measuring the actual length of the pendulum this error may be further increased, for the problem assumes the perfect parallelism and truth of a pair of knife-edges. For an account of knife-edge bar pendulums, see Kater's *Convertible* Pendulum, with Young's Appendix, 'Phil. Trans.,' 1818, p. 33; Kater's *Invariable* Pendulum, 'Phil. Trans.,' 1819, p. 337; Sabine's Experiments to determine the Figure of the Earth, London, 1825; Sabine's Comparison of the Length of Pendulum at London and Greenwich, 'Phil. Trans.,' 1829, p. 83; Sabine, On the Reduction to a Vacuum, 'Phil. Trans.,' 1829, p. 207; Baily, On the Reduction to a Vacuum, 'Phil. Trans.,' 1832, p. 399; Foster's Pendulum Experiments, edited by Mr. Baily, 'Mem. Ast. Soc.,' vol. vii. (at page 96 is given a table of the results of the most accurate modern pendulum experiments). See also WEIGHTS AND MEASURES.

Kater's Invariable Pendulum.

The last important measurement of the length of the pendulum, which is undoubtedly the most satisfactory, is due to Bessel, and is described by him in his 'Untersuchungen über die Länge des einfachen Secundenpendels,' Berlin, 1828, which forms part of the 'Transactions of the Academy of Berlin.' The principle of his measure is the same as Hatton's. Bessel procured from Paris a verified copy of the toise of Peru; this he placed upright, and suspended his ball and wire first from the top and then from the bottom of the toise, the ball being in both cases at the same point below: the time of oscillation in each position was compared with a clock in front. From the difference of the times of oscillation of these two pendulums, and the difference in their length, which is a toise, the length of the seconds pendulum was computed in parts of the toise. Bessel suspended his pendulum by passing a flat and very slender spring over a small cylinder, the spring being continued downwards to the ball in a fine wire. We must refer to the original memoir for a description of the different elaborate contrivances which were introduced by Bessel and Repsold for securing accuracy in every part of the process. All conceivable causes of error are considered, and the effects have been computed and allowed for. The final result is that the length of the seconds pendulum at the sea-level in the latitude of Königsberg, 54° 43′ N., is 440·8179 lines of the toise of Peru; this we consider to be a measurement of the actual

---

from the end c, these may be made to agree after two or three trials, or if the pendulum should be too short, a weight may be added at this end, such as is pointed out by the black dot near c.

* Mr. Baily uses two slips of gold leaf pasted on a tail to his clock pendulum for a disc, which answers very well. In the experiments at Dolcoath mine, Messrs. Airy and Whewell had a disc of enamel at the end of a small rod, which was screwed into the bob and projected from it. The disc could be inclined so as to appear of the proper breadth and to receive an oblique illumination. This part of the experiment is almost irreproachable, but perhaps in future it would be safer to place the clock and pendulum at greater distances from each other, and to get sharp edges by interposing a lens.

† Captain Kater's measure was doubtful in several respects, and though it has been partially corrected, it is still uncertain. He expressed the length of the pendulum in terms of Sir George Shuckburgh's scale (which has probably suffered injury since that time), and this he found to be identical with the parliamentary measure declared to be standard by the 5 Geo. IV., c. 74. The Act of Parliament standard was destroyed when the houses of parliament were burned. Fortunately a very beautiful scale of 5 feet had been previously made for the Astronomical Society, and three feet in this scale had been compared many hundred times with the parliamentary standard. As almost all the recent scales and comparisons which have been made in England have been compared with this last-mentioned scale, it must be considered to be the scientific English standard, and the best evidence of the parliamentary standard which exists. The definition for restoring the yard, if lost, according to the Act of Parliament, that is, by the length of the seconds pendulum, as it depends upon an erroneous determination, would give a new standard, differing sensibly from the previous one which it was meant to preserve. (Baily's Report on a Standard Scale, 'Astron. Soc. Mem.,' vol. ix. p. 35.)

length of the pendulum, and perhaps the only one, which is deserving of full confidence.

We have already pointed out the manner in which experiments with the pendulum are used to determine the figure of the earth, and stated that for this purpose the simple bar with a knife-edge at the point of minimum oscillation seems the most fit. If the present imperfections can be overcome, which we see no reason to despair of, there is another research, that of the mean density of the earth, for which such an instrument is peculiarly adapted. The density which has been hitherto acquiesced in, depends on the attraction of Schehallien upon a plumb-line, observed by Maskelyne, and upon the attraction of leaden balls measured by a torsion balance, according to Cavendish, and more recently by Reich. Now in the Schehallien experiment the whole deflection caused by the mountain was only 11″·2, which, under the circumstances, might very easily be 2″ or even 3″ wrong either way. The Cavendish experiment has been repeated in this country by Mr. Baily, who from upwards of 2000 experiments has arrived at the result 5·67 as the density of our globe. Still however it was desirable to adopt other modes of experiment, which we now proceed to point out.

If an invariable pendulum can be made which is only affected by known causes of which the effects can be calculated, the simplicity and perfection of the observation by coincidences, and the unlimited time for which it can be carried on, will supply a much broader and more secure base for the solution of this important problem, and one more readily and universally applicable. Two attempts were made by Messrs. Airy and Whewell, first by themselves, in 1826, and afterwards, in 1828, with the assistance of three Cambridge friends, to deduce the mean density of the earth from observing the oscillations of detached pendulums at the top and bottom of Dolcoath Mine, one of the deepest in Cornwall. As the first operation was less carefully planned, we shall confine our account to the second, which was altogether the best arranged pendulum experiment which had come to our knowledge up to that time, and only failed from a cause then first discovered, namely, that invariable pendulums of Kater's construction are very uncertain and inaccurate instruments. We will call the two pendulums 1 and 2. These were placed on their stands opposite each other, and put into motion at the same arc (a board being interposed to prevent their reciprocal action through pulses of the air), and the times of coincidence observed. A few series were thus made, in which the errors of observation scarcely amounted to a hundredth of a second per day.* Pendulum 1 was then sent to the bottom of the mine, and and set up with its clock and proper accompaniments. Pendulum 2 was established with its clock in a hut at the surface. We will call the observers A, B, C, D, E. A set off at six in the morning, commenced a series with pendulum 2, and compared eight pocket chronometers with the clock by coincident beats through a sidereal half-seconds chronometer.† He then descended the mine and commenced a series, compared his chronometers below exactly as he had done above, and then sent them back to the upper station. By this time E had arrived at the upper station to finish the series which A had begun, and to compare the chronometers on their return. In this way the clocks were compared, without a possible error of $\frac{1}{20}$th of a second. After finishing his first series and commencing a second, A returned to day (in the miner's language, to *grass* ‡). This series was completed by B, who set off at 2 P.M., made a third shorter series, and commenced a fourth. The night-work was taken by C or D, one of whom descended at 10 P.M., finished B's series, and commenced a fresh one; on his return to day he finished the upper series which E commenced before going to bed, and started another, which was finished by A before his next descent. In this way observations were continued from Monday morning, July 11, to Saturday afternoon (127 hours). On comparing the results of each day, it was found that the three first days agreed extremely well, showing an acceleration of about 2^s per day in the lower pendulum; but the two next days, this acceleration was about double. The only mode of accounting for this unexpected and very unwelcome result was, that the knife-edges and agate planes were imperfect, and that the time of oscillation depended on the position of the pendulum on its plane. This had never been suspected before; for confidence in the accuracy of the pendulum was at that time almost an article of faith among experimentalists. To ascertain this, a second series of comparisons was made between pendulum 1 and 2, taking care to place the knife-edges exactly in the same position on their planes, and that the faces were turned the same way. These comparisons were necessarily hurried, as a slip had taken place in the mine near the engine-shaft, which deranged the action of the pumps, and forced the experimenters to repeat their operations below without delay. Pendulum 1 was again sent below, and the experiment repeated exactly as described above, for three days (79 hours), until the underground observers were driven out by the water. Notwithstanding all the precautions which had been taken,* the observations of the last day gave a different result from the two first. "The conclusion therefore on which the experimenters were unavoidably forced was, that even with the care and attention they had used, the pendulum could not be trusted." The pendulums were a third time compared with each other above ground, and the intervals of coincidence were found to vary, without any assignable cause, from $20^m\ 24^s$ to $20^m\ 17^s$, and back again from $20^m\ 20^s$ to $20^m\ 29^s$; and finally, *during one series of oscillations, without being touched, or any one entering the room*, the time of coincidence changed from $20^m\ 25^s$ to $20^m\ 13^s$, and at last to $20^m\ 3^s$. It was therefore clear that while the mode of observing was perhaps sufficient to detect a difference of a hundredth of a second a day (except from the effects of temperature, which might amount to a tenth of a second), the pendulums themselves, though used with the utmost skill and precaution, and *under the same circumstances*, were liable to errors of two seconds or more per day.

In 1854 Mr. Airy repeated this experiment under more favourable circumstances on the banks of the Tyne, and at the bottom of a pit of Harton colliery, one of the deepest coal-pits in this country (1260 feet below the surface). Advantage was taken of electro-telegraphy to make the comparisons between the upper and lower pendulums, which were found to differ in rate 2¼ seconds per day, from which it followed that the gravity for that depth was increased by the $\frac{1}{19200}$th part. The density of the earth as deduced from this result is between six and seven times that of water, but Mr. Airy imagines that he has not taken full account of the hollow of the Tyne, of the basin named Jarrow-slake, of the scoop indicated by the sea, and of the real and observed specific gravity of the rocks which cover the mines of Harton. Further details on this subject will be found under EARTH, MEAN DENSITY OF THE. [See also GYROSCOPE.]

PENETRABILITY. Under IMPENETRABILITY are given a few examples of the apparent penetration of one body by another; and, indeed, examples of this kind are more apparent than real. There are many instances in chemistry in which a body is dissolved in water, or other liquids, without visible increase in bulk. A measure of sulphuric acid mixed with one of water, will give less than the sum of the two; but it is not supposed that in such cases there is any penetration of matter, but only an alteration in density, and in the relation of the compound to heat, &c.

PENITENTIARIES. [PRISONS.]

PENITENTS. [PENANCE.]

PENNY. [COIN; MONEY.]

PENSION, an annual sum granted by the state to an individual. The grounds upon which pensions are granted by the state differ according to the nature of the government. In a monarchy the services rendered to the sovereign by those who surround his person will recommend them as fitting objects of reward: where a mixed form of government prevails, attempts will be made to establish some standard of reward independent of personal bias or caprice. In this country the distribution of pensions is now almost entirely subject to the control of the legislature; but the following notice will show that persevering and long continued-efforts have been necessary to place it upon this footing.

Before the reign of queen Anne, the kings of England alienated or encumbered their hereditary possessions at pleasure, and the courts of law sustained them in the exercise of this power. In 1690-91, Chief-Justice Treby, in answer to the objection that such power might lead to the destruction of the revenue, said, "This might be some reason to induce the making of an act of parliament to restrain the king's power of alienation; but since here the parliament has thought fit to give the king such a power, we ought to acquiesce and submit to it." ('State Trials,' vol. xiv., p. 30.) By the 1 Anne, c. 7, the right of burdening the revenue of the crown with improvident grants, to the injury of the successors of the throne, was materially abridged. This statute, after reciting that "the necessary expenses of supporting the crown, or the greatest part of them, were formerly defrayed by a land revenue, which had from time to time been impaired and diminished by the grants of former kings and queens of this realm," enacts that no grant of manors, lands, &c., shall be made by the crown from and after the 25th of March, 1702, beyond the term of thirty-one years or for three lives, reserving a reasonable rent. As this clause applied only to the land revenue, it was enacted by another clause that no portion of other branches of revenue, as the excise, post-office, &c., should be alienable by the crown beyond the life of the reigning king. On the accession of George III., in consideration of the surrender of the larger branches of the hereditary revenue, a civil list was settled on his majesty, amounting originally to 800,000*l.*, and afterwards increased to 900,000*l.*, on which the pensions were charged. There were no limits, except the Civil List itself, within which the grant of pensions was confined; and at various times, when debts on this list had accumulated, parliament voted considerable sums (Sir Henry Parnell, in his work on 'Financial Reform,' says "some millions") for their discharge. In February, 1780, during the administration of Lord North, Mr. Burke introduced his bill for the better security of the independence of parliament and the economical reformation of the civil and other establishments. In this bill it was recited that the pension lists were excessive, and that a custom prevailed of granting pensions on a private list during his majesty's pleasure, under colour that in some cases it may not be expedient to divulge the names of persons on the said lists, by means of which much secret and dangerous corruption may be hereafter practised. Mr. Burke proposed to reduce the English pension list to a maximum of 60,000*l.*, but the bill, as passed, fixed it at 95,000*l.* This act (22 Geo. III., c. 82) asserted the principle that distress or desert ought to be considered as regulating the future grants of such pensions, and that parliament had a full right to be informed in respect to this exercise of the prerogative, in order to ensure and enforce the responsibility of the ministers of the crown. Mr. Burke's speech on introducing his bill will be found in the third volume of his 'Works,' ed. 1815.

---

* In a series of six hours, the first and last coincidences could be so observed as not to admit an error of more than 2^s for the whole interval, and the coincidences followed each other in about twenty minutes. A bright strip was rubbed off each edge of the tail of the farther and quicker pendulum, and this was illuminated by a lamp placed obliquely. The corrections for arc, barometer, temperature, were the same for each. The time was taken from an excellent chronometer.

† The comparison of a single chronometer was scarcely ever in error $\frac{1}{30}$th of a second, generally within $\frac{1}{50}$th. The ½ seconds sidereal chronometer was compared first and last with the pendulum clock, going nearly solar time, and in the interval three or five coincidences of each pocket chronometer (which beat $0^s{\cdot}4$ solar time) were observed with the sidereal chronometer.

‡ A miner divides the visible world into two parts, *underground* and *at grass*.

* A considerable difference was found in the temperature of the upper and lower part of the hut during the first upper ground experiment, from the heat of the lamp for illuminating the disc, which was kept continually burning. Before the second experiment, a side lobby was boarded off, in which the observer placed the illuminating lamp a minute or two before the coincidence took place. The lamp-light was thrown by a reflector on the disc through a hole in the boarding; and when the coincidence had been observed, the lamp was withdrawn and the hole stopped with flannel. The clock-face was illuminated for a short time before coincidence by a lamp with a powerful reflector through a hole in the front partition, which was also withdrawn and the hole stopped when the observer had caught the number of the beat. With these precautions, the temperature was perfectly steady, and sensibly the same at all altitudes and throughout the twenty-four hours.

Up to this time the Civil List pensions of Ireland, the pensions charged on the hereditary revenues of Scotland, and the pensions charged on the 4½ per cent. duties, had not been regulated by parliament.

In Ireland the hereditary revenue of the crown was used as a means of extensive political corruption, the English act of 1 Anne, already cited, not being applicable to Ireland. In a speech of Mr. Hutchinson, secretary of state, made in the Irish House of Commons, in June, 1793, he stated that the gross annual hereditary revenue of Ireland amounted to 764,627*l.*, reduced by various charges to 275,102*l.* only; that the disposition of this revenue was in the hands of the king; that "his letters and seals were the only authority for using it, and the only voucher allowed by the Commissioners of Accounts and by the House of Commons;" and that there was no Board of Treasury executing their functions under the authority of parliament. The Irish parliament, in 1757, had come to a unanimous resolution, "That the granting of so much of the public revenue in pensions is an improvident disposition of the revenue, an injury to the crown, and detrimental to the people." The Irish pensions then amounted to 40,000*l.*: in two years after the above resolution was passed, an addition of 26,000*l.* was made to them; and in 1778 they were nearly double the amount at which they stood in 1757. In 1787 leave was refused to bring in a bill to limit the amount of pensions, and to disable persons holding pensions for a term of years, or during pleasure, from sitting and voting in parliament. Mr. Forbes, who moved this bill, stated that "it was a practice among certain members of the House to whom pensions had been granted, to carry them into the market and expose them for sale." In 1790 Mr. Forbes again moved resolutions, stating "that the Pension List amounted to 101,000*l.*, exclusive of military pensions; that the increase of pensions, civil and military, since February, 1784, had been 29,000*l.*; and that many of these pensions had been granted to members of parliament during the pleasure of the crown." These resolutions were not adopted. In 1793, when the whole policy of the Irish government was changed, among other beneficial measures introduced and recommended on the authority of the lord-lieutenant was a bill to limit the amount of pensions and to increase the responsibility of the Treasury, which was passed into a law. By this act (33 Geo. III., c. 34, Irish statutes) the pensions on the Civil List in Ireland were limited to 80,000*l.*, allowing a sum of 1200*l.* only to be granted until such reduction was effected. Grants held during the pleasure of the crown, and converted into grants for life to the same parties and to the same amount, were exempted from the limitations of the act. This act carried into effect a surrender of the hereditary revenues for the life of the king, and the principle of appropriating money by parliamentary authority. These restraints on the crown were not however equal in efficiency to those contained in the English statute of Anne. At the time of the act of 33 Geo. III. being passed, the Irish pensions amounted to 124,000*l.*, and the amount was not reduced to 80,000*l.* until 1814. By the 1 Geo. IV., c. 1, the Irish Pension List was further reduced to 50,000*l.*, no grants exceeding 1200*l.* to be made in any one year until the list was so reduced.

The statute of 1 Anne, having been passed prior to the Union, did not affect Scotland; and pensions were accordingly granted by the crown for life or for lives, in possession or in reversion, without restriction in amount or in the duration of the grant, other than the amount of the revenues and the claims and burdens already upon them. By the 50 Geo. III., c. 3, the principle of parliamentary interference was established in reference to the hereditary revenues of Scotland, the amount of the pensions was reduced to 25,000*l.*, and no more than 800*l.* was to be granted in any one year until such reduction was effected. At this period the Civil List pensions of Scotland amounted to 39,379*l.* By the 1 Geo. IV., c. 1, the hereditary revenues of Scotland were placed to the account of the consolidated fund.

Certain duties, called the 4½ per cent. duties, were not withdrawn from the private control of the crown until 1830, when they were surrendered by William IV. for his life, the pensions then chargeable upon them continuing payable. On the acession of William IV. there was nothing therefore to prevent the Pension Lists of England, Ireland, and Scotland being consolidated; and this was effected by 1 Will. IV., c. 25, which also made provision for their reduction, on the expiration of existing interests, from an amount of 145,750*l.* net, to a future maximum sum of 75,000*l.* The Pension List for England was at this period 74,200*l.* net; Scotland 23,650*l.*; Ireland, 47,900*l.*

In 1830 the ministry of the Duke of Wellington was overthrown on the question of referring the Civil List (which comprises the Pension List) to a select committee, Sir Henry Parnell's motion to that effect being carried by 233 against 204.

In February, 1834, in order to define with greater precision the class of persons to whom the grant of pensions ought to be confined, Lord Althorp, chancellor of the exchequer (afterwards Earl Spencer), moved resolutions to the following effect, which were agreed to by the House of Commons:—"That it is the bounden duty of the responsible advisers of the crown to recommend to his majesty for grants of pensions on the Civil List such persons only as have just claims on the royal beneficence, or who, by their personal services to the crown, by the performance of duties to the public, or by their useful discoveries in science, and attainments in literature and the arts, have merited the gracious consideration of their sovereign and the gratitude of their country."

On the accession of Queen Victoria, in 1837, the subject of pensions was again considered; and a select committee of the House of Commons, appointed to inquire into the Civil List, recommended,—"That in place of granting a sum of 75,000*l.* for Civil List pensions, her Majesty should be empowered to grant in every year new pensions on the Civil List to the amount of 1200*l.*, these pensions to be granted in strict conformity with the resolutions of the House of Commons, of February, 1834." These views were adopted by the House, and embodied in the 1 Vic., c. 2, the words of the resolution being introduced into the Act. Since the accession of Queen Victoria, still greater force has been given to the spirit of the Act, in consequence of the recommendations of a select committee of the House of Commons, appointed in December, 1837, to inquire how far the pensions charged on the Civil List, as settled on the accession of William IV., ought to be continued, "having due regard to the just claims of the parties and to economy in the public expenditure." This committee after a searching and protracted inquiry into the merits of each case on the Pension List, recommended the immediate suspension of several pensions, to be regranted on the responsibility of the government, should the circumstances of the parties render it necessary; others they considered should determine at an earlier period than specified in the original grant; and for several pensions, they considered it unadvisable to make any future provision. In their report, dated July, 1838, the committee recommended that in the case of all future Civil List pensions, the reasons and motives of the grant should be set forth in the warrant of appointment; that in pensions granted for services to others than the individual by whom the services were rendered, care should be taken, if these pensions are granted for younger lives, that is, to the sons or daughters of the individual entitled to the pension, that no undue increase of charge should be made; and that such grants should be avoided, except under very peculiar circumstances: they recommended also that pensions for the relief of distress should be granted only on the condition of their ceasing when the circumstances of the parties no longer require their continuance; that all pensions should be held liable to deduction or suspension in the event of the parties being appointed to office in the public service; that under no circumstances should the mere combination of poverty with the hereditary rank of the peerage be considered as a justification of a grant of pension. The committee also recommended that, in order to avoid any possible doubt or misconception hereafter, enactments should be made with respect to the Irish and Scotch revenue analogous to those contained in the English statute of 1 Anne.

Besides the pensions on the Civil List, the regulation of which at different periods has been referred to above, there are vast sums annually appropriated by parliament to the payment of pensions of another description. Thus in 1860-1 the sum of 1,063,371*l.* was voted on account of the out-pensioners of Chelsea Hospital, 58,469 in number; 232,764*l.* to the out-pensioners of Greenwich; 135,785*l.* to 2478 widows of officers of land-forces; and to officers in each of the civil departments of the government large sums are annually paid in pensions and superannuation allowances. The half-pay to retired officers of the navy and army may also be considered in the light of a pension. The Civil List pensions in the year ending June 20, 1860, amounted to 1500*l.*, divided among twenty-two recipients.

PENSIONARY, GRAND, was the name generally given to the first magistrate of the state or republic of Holland, which was a member of the confederation of the Seven United Provinces of the Netherlands. The Pensionary was the president of the council of states or legislature of Holland, and he was at the same time the first minister of the republic, and transacted business with foreign powers, like the Avoyer of Bern and other Swiss cantons. He was elected for five years, but was generally confirmed indefinitely, and often for life. He was also, in virtue of his office, the perpetual deputy of the state of Holland to the assembly of the states-general of the United Provinces, of which he was a most influential member, in consequence of the superior importance of the province of Holland. His name was derived from the pension which was attached to his office. He was also styled advocate-general to the states of Holland. The individual chosen for this high office was a person well versed in the science of the law, and he is styled by Grotius "Adsessor Jurisperitus." The various towns of Holland and Zealand had also each their pensionary, or chief municipal magistrate.

PENSTOCK, a kind of small sluice or floodgate, employed to retain or let go at pleasure the water of a mill or other pond. A cut of a simple form of penstock sluice is given under Irrigation. [Sluice.]

PENTACHLORXYLON ($C_{10}H_5Cl_5O_4$). One of the chlorinated products of the decomposition of creasote.

PENTACHORD, an ancient Greek musical instrument, which had, as the word implies, five strings. The term also signified a scale of five sounds.

PENTATEUCH (*Πεντάτευχος*, from *πέντε*, "five," and *τεῦχος*, "a volume") is the Greek name of the first five books of the Old Testament, which are called in Hebrew תּוֹרָה, "the law." The Hebrew copies of the Pentateuch form one volume; the division of it into five books is first mentioned by Josephus, and seems to have been made either by the Septuagint translators, or before their time, and after the return of the Jews from Babylon.

The five books of the Pentateuch have been treated of under Genesis, Exodus, Leviticus, Numbers, and Deuteronomy.

With regard to the Pentateuch in general, it has never been doubted, till at a recent period, that Moses was its author. The following are the chief arguments for its genuineness:—1. It is repeatedly asserted in the book itself that Moses was the author, and that he wrote it at the command of God. This assertion is made with regard to the whole book (Deut. i. 5; xxxi. 9-13, 22, 24-26), and to separate parts of it (Exod. xvii. 14; xxiv. 4, 7; xxxiv. 27; Numb. xxxiii. 1, 2). And in the recapitulation of the law which Moses makes in the book of Deuteronomy, he frequently speaks of "the law," "this law," "the book of the (or this) law," "the book of religion;" by which expressions we cannot fairly understand anything except either the whole Pentateuch, or that part of it which was already composed. (Deut. i. 5; iv. 44-45; xvii. 18, 19; xxviii. 58-61; xxix. 19, 20, 27, 29; xxx. 10.) 2. In all ages of the Jewish history, from the time of Joshua downwards, the Pentateuch was received as the divinely inspired composition of Moses. Thus we read repeatedly in the Old Testament of "the law," "the law of Moses," "the law of Jehovah," "the law which God gave by Moses," "the book of the law." (Josh. i. 7, 8; xxiii. 6; xxiv. 26; 1 Kings ii. 3; Psalms i. 1; and many other passages, which are collected in Rosenmüller's 'Scholia,' and Jahn's 'Introduction.') Besides these direct testimonies, the existence and authority of the Pentateuch among the Israelites are proved by the fact that the institutions which it contains were always observed as the laws of their nation, and that the sentiments of the Psalmists, the maxims of the Book of Proverbs, and the reproofs and exhortations of the prophets, are all exactly in agreement with the spirit of those institutions. 3. The internal evidence is strongly in favour of Moses being the author. The language of the book of Deuteronomy is that of an aged man addressing the people whom he had governed for forty years, appealing to their past experience, and speaking with all the earnestness of a man on the verge of death. If these characteristics are of any weight to show that the speaker and the writer of this book were the same, then we are supplied with an argument for the genuineness of the *whole* Pentateuch; for the book of Deuteronomy supposes the previous composition of Exodus, Leviticus, and Numbers, as these do that of Genesis. The information contained in the Pentateuch on subjects of history and geography (especially with reference to Egypt and Arabia), on natural history, diseases, the arts, and military science, agrees with all the notions we can form of the state of things at that remote period, and with what we should expect from a man who, like Moses, had been liberally educated at the Egyptian court, and had been engaged for forty years in leading a whole nation through the wilderness. The language of the Pentateuch is the most ancient known form of Hebrew. The style of the songs which are contained in it possesses that plain sublimity which generally characterises the first stage of a nation's poetry. The style of the narrative is better than that of any other Hebrew work, as we might expect from a highly educated man like Moses; and it is not more varied than can be accounted for by the different subjects treated of, and the intervals at which the different parts were written. The arrangement of the matter is not that which would be adopted by a person digesting into one book previously existing tales and laws; but it is such as we might expect from one exposed to frequent interruptions in his work, and who recorded each event as it occurred, which answers to the position of Moses. The selection of the materials appears to have been made on the principle of recording those things which were connected with the legislation which was the chief work of Moses; while of the laws themselves, some are repeated more than once, and others altered in the course of the work; all indicating that the legislator and historian were the same person.

It is true that there are passages in the Pentateuch which could not have been written by Moses. But there is no difficulty in explaining these passages as interpolations, inserted by a copyist with a view to make the author's meaning clearer. The following passages have been placed in this class; but some of them may be explained otherwise:—Deut. i. 1-4; iv. 44-49; Exod. vi. 13-29; vii. 7; xi. 1-3; Deut. ii. 10-12, 20-23; iii. 9, 11, 13-14; x. 6-9; Numb. xxxii. 41; Deut. iii. 14; Numb. xii. 3. To these may be added the 34th chapter of Deuteronomy, which, as it contains an account of the death and burial of Moses, was not written by himself. In some parts, however, of his narratives, Moses appears to have made use of previously existing documents, especially at the beginning of the book of Genesis. [Genesis.]

The Pentateuch was the only part of the Old Testament which the Samaritans received; and as, from feelings of national animosity, they held no intercourse with the Jews, their copies of the Pentateuch were preserved independently of the Hebrew copies. The Samaritan Pentateuch is mentioned by several ancient writers; but it was unknown in modern times till copies were obtained from the east by Archbishop Usher and Pietro della Valle. It was printed from the copy procured by the latter in the Paris Polyglot of Morinus, from which it was reprinted in Walton's Polyglot. It was also edited by Dr. Blayney in Hebrew characters, at Oxford, 1790. The original is in the Samaritan or old Hebrew character.

The Samaritan Pentateuch is quite entitled to rank with the Hebrew as an independent source for settling the sacred text. In some places it gives readings manifestly superior to those of the Hebrew. In many passages, in which it differs from the latter, it agrees with the Septuagint. Its chronology differs from that of the Hebrew Pentateuch. (Hales's 'Analysis of Chronology,' vol. i., p. 272.) In Deut. xxvii. the Samaritan differs from the Hebrew by having Ebal for Gerizim, and *vice versâ*. This has been regarded as an intentional corruption, made for the purpose of humouring national prejudices; but Dr. Kennicott has shown good reasons for preferring the Samaritan to the Hebrew in this case. ('Diss.' ii., pp. 20-165.)

The authenticity of the Pentateuch is also substantiated by passages in the later books of Holy Scripture, showing that there had been an uninterrupted belief in its authenticity. Thus it is quoted in 2 Kings xiv. 6, and xxiii. 2; 2 Chron. xxxv. 6; Ezra iii. 2, and vi. 18; Nehemiah i. 7; Amos ii. 9 and 10; Isaiah i. 9 and 14; and Micah vi. 5, where the books of Moses are directly quoted or alluded to. Christ and his apostles also acknowledge their authority by quoting them. Thus we have all the evidence of their authenticity that the nature of the case admits.

An account of the institutions recorded in the Pentateuch has been given under Moses, in Biog. Div.

(Rosenmüller, *Scholia in Vet. Test.*, vol. i., *Proleg. in Pent.*, and others quoted by him; Jahn, *Introd. in Lib. Sac. Vet. Foed.*; Hengstenberg, *Die Authentie des Pentateuchs*, 1836; Graves's *Lectures on the Pentateuch*; Bp. Marsh's *Authenticity of the Five Books of Moses vindicated*; Horne's *Introduction*, vol. i.; and Blunt, *Veracity of the Five Books of Moses.*)

PENTATHIONIC ACID. [Sulphur.]

PENTECOST, one of the three great Jewish feasts, so called because the day on which it began was the fiftieth (*ἡ πεντηκοστή*) from the second day of the Passover. It was also called the Feast of Weeks, from its falling at the end of a series of seven weeks, reckoning from the Passover, and also the Feast of the Harvest. It was a feast of thanksgiving for the harvest, at the end of which it fell, and among the sacrifices appointed for it were some of the first-fruits of the harvest. This festival lasted eight days. The laws relating to it are contained in Exod., xxiii. 16; xxxiv. 22; Levit., xxiii. 15–21; Numb., xxviii. 26–31; Deut., xvi. 9–12.

PENUMBRA (incomplete shade), that portion of space which, in the eclipse of a heavenly body, is partly, but not entirely, deprived of its light. In a solar eclipse, as long as any part of the sun is visible, the parties observing are in the penumbra, and not in the *umbra*, or complete shadow.

PEPPER-CORN RENT. [Rent.]

PEPPERMINT, ESSENTIAL OIL OF. Obtained by submitting the fresh herb [Mentha *piperita*, in Nat. Hist. Div.] to distillation with water, in the manner already described. [Essential Oils.] It is colourless when first prepared, but gradually acquires a yellow tint; has a characteristic, pungent, aromatic taste, and a peculiar odour, resembling that of the plant. Several varieties of it exist in commerce. [Mentha Piperita.]

Oil of peppermint consists of a camphor, or stearopten, and a liquid portion, or eleopten. The latter has not been minutely examined. English oil contains but little stearopten; American oil yields a considerable quantity; while the Chinese variety is wholly stearopten.

Peppermint camphor ($C_{20}H_{20}O_2$), as the stearopten is called, forms colourless prismatic crystals, is fusible at 87° Fahr., and may be volatilised without undergoing decomposition. Its boiling point is 406·4; vapour density, 5·82. It is only slightly soluble in water, but readily so in wood spirit, alcohol, ether, and bisulphide of carbon, and tolerably so in oil of turpentine. Phosphoric acid converts it into MENTHENE.

Oil of peppermint is much adulterated with turpentine. The latter can generally be detected by the nose; while the pure oil is distinguished from the other mint oils by the deep red-brown colour which is imparted to it by chromate of potash.

PER. A prefix used in chemistry. [CHEMICAL NOMENCLATURE.]

PERAMBULATION. A perambulation is a walking through or over ground for the purpose of settling boundaries. A perambulation of a parish for this purpose is made by the minister, churchwardens, and parishioners in Ascension-week, at periods varying from one to three years. Usage will justify the parishioners in following the boundary over any man's land. Manors and lordships also are or may be perambulated: and there is a writ De Perambulatione faciendâ, which ought to be sued with the assent of both parties when they are in doubt about the bounds of their lordships or manors. The writ is addressed to the sheriff, who is to execute it and make his return to the justices at Westminster on a certain day; or to the justices of assize, under his seal, and the seals of those who make the perambulation with him. The king may direct the writ to other persons to make the perambulation, as well as to the sheriff. This perambulation made by assent binds the parties and their heirs. But unless both parties who assent to the perambulation are tenants in fee-simple, it seems that the perambulation shall not bind him who is in reversion.

Questions of boundaries are now generally determined, however, by actions of trespass or ejectment.

It was an old Roman practice at the time of the Terminalia, in the month of February, to perambulate the boundaries of a district or community. The original boundaries of the territory of Rome, which extended six miles from the city, were perambulated at the Terminalia; the boundaries between private properties were also perambulated at the Terminalia, and the usual religious offerings were made. This ancient and simple mode of preserving boundaries probably fell into disuse as the land-surveyors became more skilful, and the records of boundaries were better kept. It is stated that the practice fell into disuse with the establishment of Christianity. But this is not probable. The religious ceremonies might be changed or dropped: but the fact of perambulations being still kept up in this country in the case of parishes, leads to the conjecture that the practice extended from Rome to other countries which the Romans occupied, and was retained in some form among the Christianised people in the provinces.

PERAMBULATOR, an instrument in general use for measuring distances on roads, for settling disputes concerning the charges of the drivers of hack-carriages, and for other purposes. It consists principally of a wheel upon which it runs, and an index which shows the number of turns of such wheel reduced into miles, furlongs, poles, and yards.

The carriage or stock is made of wood, and is about 3 feet long. At one end is a handle for the person who uses it, and the other is furnished with sockets in which the axle of the wheel turns; this end of the stock has the centre part removed, by which are left two arms between which the wheel works. Upon the stock and just in front of the handle is the dial-plate, with its two hands by which the distance is registered. The wheel is 8 feet 3 inches, or ½ pole, in circumference. Upon one end of the axis of this wheel is a small pinion, which works into a similar pinion at the end of a rod which passes up the stock or carriage to the works beneath the dial-plate. Motion is communicated by means of this rod to a worm or micrometer-screw, which turns once round for each revolution of the carriage-wheel of the perambulator. This worm works into a wheel of 80 teeth, which is moved forward one tooth for every ½ pole, and carries a hand or index, which makes one revolution for 40 poles or one furlong. On the axis of this wheel is a pinion of 8 teeth, which works into a wheel of 40 teeth, and on the axis of this second wheel is a pinion of 10 teeth, which moves a wheel of 160 teeth. This last wheel carries another hand, which makes one revolution for 80 of the former. These hands are arranged in the same manner as the hour and minute hand of a watch, so that the three circles on the dial-plate are all concentric. The first of these circles is divided into 220, and the second into 40, the number of yards and poles contained in a furlong; the figures on these circles are read off by the first-mentioned index, that which is attached to the wheel of 80 teeth. The third circle is divided into 80, the number of furlongs in 10 miles, and to this circle belongs the index attached to the wheel of 160 teeth. The distance is ascertained by reading off the figures in the reverse order in which the circles are given above: divide the number on the first circle by 8, and you will have the distance required in miles, furlongs, poles, and yards.

The instrument is furnished with a stop or strap, so that after the distance is measured, the perambulator may be conveyed without the index being altered.

Unlike the pedometer, it requires no regulating, and the only risk of its giving the distance incorrectly, if well constructed, is in passing over rugged and uneven roads, which will of course cause the index to show more than the true distance. In general, however, for short distances, this error is very trifling.

When about to commence a measurement, the wheel should be turned round until the first-mentioned index points to 220 on the circle of yards. Some are provided with a click and racket, by which this may be done with much less trouble than by the wheel.

There are other instruments for the same or similar purposes, bearing different names, *waywiser* and *odometer;* but the construction of all of them is very similar.

Waywiser is the name generally given to that form of the instrument which is applied to a carriage, in which, by a slight adaptation to one of the wheels of the carriage, the instrument is made to register the number of turns of such wheel, in the same manner as the perambulator.

PERCEPTION is that power or act of the mind by which it holds communication with the external world. It is distinguished from *conception* by the circumstance that its objects are in every instance supposed to have an actual existence. We may conceive things that have no reality, but we are never said to perceive such things. Perception differs from *consciousness* in that it takes cognisance only of objects without the mind. We *perceive* a man, a horse, a tree; when we think or feel, we are *conscious* of our thoughts and emotions. It is further supposed in perception that the objects of it are present. We can *remember* former objects of perception, but we do not perceive them again until they are once more present. Besides the sense which has been explained, the term perception is sometimes analogically employed in common speech in reference to truths the evidence of which is certain. Thus we may perceive the truth of a mathematical proposition. But Mr. Hume is perhaps the only writer of eminence who designedly applies the word in a metaphysical disquisition with a meaning different from that which has been here assigned to it. By him it is applied indiscriminately to all the operations and states of the mind; passions being designated perceptions, and the acts of memory and imagination converted into so many acts of perception. Such latitude of phraseology confounds under one general name things essentially distinct, and tends to introduce vagueness and inaccuracy into a department of philosophical investigation where definiteness and precision are peculiarly indispensable.

The distinction between things *perceived* (αἰσθητὰ) and things *conceived* (νοητὰ) was familiar to the Greek philosophers and to their Latin expositors, of whom Cicero expresses the former class of things by the phrases "quæ sunt," "quæ cerni tangive possunt;" and the latter by "quæ tangi demonstrarive non possunt, cerni tamen animo atque intelligi possunt," and gives examples of each. ('Top.' v.)

The perceptive faculty is exercised through the instrumentality of the senses. We see by means of the eye, and hear by means of the ear, and so in reference to the other senses. An individual in whom these organs are wanting or defective, will either not perceive at all, or perceive imperfectly. In order to perception it is requisite that an impression should be made on the organ of sense, either by the direct application of the object, or through some medium that communicates with the object and the organ. Thus an immediate application is necessary with regard to the senses of taste and touch; but only an intermediate one with regard to those of sight, hearing, and smell. The impression made on the organs of sense affects the nerves, and is by them conveyed to the brain. The necessity of this communication is ascertained by observation. If the nerve appropriated to any organ be cut or tied hard, no perception takes place; and the same result is noticed in certain disordered conditions of the brain, even though the organs of sense and the nerves perform their respective functions. When however the conditions that have been specified are complied with, perception ensues.

Various theories have been formed to explain the functions of the nerves and brain in connection with perception. It was imagined by the ancients that the nervous fibres are tubular, and filled with a subtile vapour named animal spirits; that the brain is a gland by which this ethereal fluid is secreted; and that by means of it the nerves perform their office. (Reid, 'Essay' ii., ch. iii.) Des Cartes, who adopted this hypothesis, has described with great minuteness how all mental operations and movements are accomplished through the agency referred to. Dr. Briggs, Newton's instructor in anatomy, was the first who proposed a new doctrine on this point. He maintained that the nerves operate by vibrations, like musical chords, and thus conduct impressions to the brain. Newton himself ('Opt.,' qu. 23) appears to have been inclined to a notion of this kind, and the suggestions relating to it thrown out by him as a query were afterwards amplified and defended by Hartley. The latter supposed that "external objects impressed on the senses occasion, first in the nerves on which they are impressed and then in the brain, vibrations of the small and, as one may say, infinitesimal medullary particles;" and that these vibrations "are excited, propagated, and kept up partly by the ether, that is, by a very subtile elastic fluid: partly by the uniformity, continuity, softness, and active powers of the medullary substance of the brain, spinal marrow, and nerves." ('Observations on Man,' part i., prop. 4, 5.) Both Des Cartes and Hartley believed that by the action of the nerves in the manner described by them, images of external objects were formed in the brain.

It is scarcely necessary to remark concerning these hypotheses that they are totally destitute of foundation. A sound theory must assign real and not imaginary causes for the phenomena which it professes to explain; and such causes must have a manifest competency to the effects ascribed to them. But the hypotheses in question entirely want both of these essentials. Who can prove the existence of the animal spirits of Des Cartes, or the vibrations of Hartley; or, granting their existence, who can show any correspondence between them and the formation of images in the brain? All we can affirm with certainty respecting the means of perception is, that, under certain circumstances, that is, when an impression is made on the bodily organs and communicated by the nerves to the brain, perception takes place. The impressions so communicated are the occasions of the mind perceiving, but we can assign no reason why it should do so under these circumstances invariably, and not under any other, further than that such is the constitution of our nature.

If the act of perception be examined, it will be found that we obtain by it a certain amount of information respecting the object perceived. We discover that it has particular qualities, as for example, that it is extended, that it has figure, that it is hard or soft, rough or smooth, &c. The notion thus formed may vary in respect of distinctness in all possible degrees. In the light of twilight a body is discerned more obscurely than in the full light of noon day; and more obscurely still in proportion as the darkness deepens. The notion we get of an object by perception is accompanied by an irresistible and immediate conviction of its real existence. An object may indeed be perceived so indistinctly as to leave us in doubt whether it be real or not. If it be very distant, or involved in darkness, this may happen. But when it is plainly perceived, there is, along with the perception, a perfect conviction of its reality. We can no more doubt of its existence than we can of our own. And this conviction is immediate. It is not the result of a process of reasoning founded on our perceptions, but inseparably connected with them, and as instantaneous as the assent rendered to axiomatic truths. It may be also remarked that the belief in the existence of the objects of perception is not more immediate and deeply rooted than is the belief that they exist externally to us. They do not seem to have their place in the mind itself, but to exist independently of it altogether. These statements accord with the universal experience of mankind, and may be verified by all who choose to bestow the slightest attention on the intimations of consciousness.

It would be a tedious as well as a useless task to dwell minutely on the numerous theories that have been framed of perception. In certain important particulars nearly all of them coincide; while in others, equally if not more important, they are for the most part at variance.

Democritus taught that perception was the result of the impressions made on the organs of sense by images (εἴδωλα), which constantly emanated from bodies, and varied according to the conformation of their originals. (Plut. 'Plac. Phil.,' l. iv., ch. 8, &c.)

Plato, in the seventh book of his 'Republic' (ad init.) illustrates the manner in which we perceive objects, by the figure of a cave, in which men lie bound, so that they can turn their eyes only to one part of it, where rays from a distant light stream in, and shadows of bodies, supposed to pass between them and the light, are beheld, the bodies themselves being invisible. He thus conceived that we perceive only the shadows of things, and not things themselves.

This opinion of Plato was substantially the same with that of his scholar Aristotle, and of the Peripatetics generally. Aristotle ('De An.,' l. iii., c. 2, 3) taught that as the senses cannot receive material objects themselves, they receive their images. These images are the only objects of perception to the mind. As impressed upon the senses, they are termed sensible species; more spiritualised, they become objects of memory and imagination, and are termed phantasms; still further refined, so as to be objects of science, they are named intelligible species.

The theory of Epicurus was little other than a modification of that of Aristotle. He supposed that bodies are continually sending off from their surfaces slender films or spectres of such subtlety that they easily penetrate by the senses to the brain. (Lucret., l. iv., v. 34, 46, &c.)

Locke employs an illustration of the manner of perception that appears to have been borrowed from that of Plato:—"Methinks," he says, "the understanding is not much unlike a closet wholly shut from light, with only some little light opening left to let in external visible resemblances, or ideas of things without. Would the pictures coming into a dark room but stay there, and be so orderly as to be found upon occasion, it would very much resemble the understanding of a man in reference to all objects of sight and the ideas of them."

The similitude of Locke, or rather of Plato, may be applied to all the systems of perception that have ever been formed, by merely substituting ideas, and, in the case of Hume, impressions, for what were anciently denominated species and phantasms. All these theories agree in maintaining that images are the only immediate objects of perception to the mind. Hume, Berkeley, and others indeed hold that these are the exclusive objects; but the common hypothesis admits the existence of things of which these are but the representatives, and which we mediately discern. It may be sufficient to remark concerning these opinions, that they are diametrically opposed to the testimony of our own consciousness. Instead of informing us that images alone are the direct objects of our perception, consciousness intimates nothing respecting images at all. Unless its representations are altogether deceptive, it is not things within the mind, but things external to it, that we perceive; not images of objects, but the very objects themselves. This is testimony to which we yield instinctive credence. It is too cogent and unquestionable to be set aside by reasoning of any kind, far less by reasoning based upon certain imagined relations subsisting between matter and spirit which we are incapable of apprehending, and the application to mind of laws which apply solely to the objects of physical investigation.

One observation, intentionally deferred, remains still to be made respecting perception, namely, that it is greatly modified by habit and by the cultivation and development of the other powers. Thus the perceptions of a man and those of a child, both contemplating a piece of complex machinery, the one being aware of its principles and arrangements, the other completely ignorant of them, must in some respects considerably differ. In like manner the perceptions of a blind man, by means of those organs of sense which are unimpaired, are distinguished in many particulars from those of the individual who has never been without the faculty of vision. Numerous instances of a similar kind might easily be specified. A full account of acquired perceptions, such as those alluded to, is still a desideratum in this department of philosophical inquiry.

PERCH or POLE. This measure, though now mostly used as a square measure (a perch usually meaning a square perch, or a square of a perch in length and breadth), was originally a measure of length, arising out of the custom of measuring small portions of land by a staff or pole. The word *pertica*, from which it comes, means a wooden staff. But the pole with which land was measured not only differed very much in different countries, but in different parts of the same country. Ducange and his editors find records of the use, in different parts of England and France, of perches of 7½, 10 (the oldest English), 12, 15, 16, 18, 20, 21, 22, 25, and 27 feet. Here is but another instance (as in MILE and LEAGUE) of the tendency of measures to lengthen. Forty perches (quarantena), under the name of forty-long or furlong, became a common measure of length; and a piece of land forty perches long and one deep, was called *perticata*. (Spelman, cited by Ducange.) Thus the perch and furlong, though afterwards received into the system of measures which ends with the mile, originally formed no part of it whatever. [MILE.]

By an early statute, entitled 'Compositio Ulnarum et Perticarum,' the perch was fixed at 16½ feet, or five yards and a half; and four perticatæ (though that word is not used) were defined as an acre.

A perch is the quarter of a chain, and a square perch contains 30¼ square yards.

PERCHLORIC ACID. [CHLORINE.]

PERCHLORINATED QUINONE. [QUINONE.]

PERCHLOROXYNAPHTHALIC ACID ($C_{20}HCl_5O_6$). *Chloroxynaphthalesic acid.* When perchloroxynaphthyl is placed in contact with potash it is instantly transformed into a magnificent carmine-coloured body, which is the potash salt of this acid. The acid itself is yellow, insoluble in water, but soluble in boiling alcohol. The ammonia salt, which is of a bright red, is, like the potash salt, quite insoluble in water. This acid may be regarded as pentachlorinated alizarine.

PERCHLORRUBIAN. [MADDER, COLOURING MATTERS OF.]

PERCUSSION, CENTRE OF, the point of a system which moves about a fixed axis, at which a force may act in such a manner as to produce no pressure on the axis. Its distance from the axis is the same as that of the centre of oscillation. [OSCILLATION.]

PERCUSSION, in medicine, is the method of eliciting sounds by striking the surface of the body, for the purpose of determining the condition of the organs subjacent to the parts struck.

This means of diagnosis was first employed by Avenbrugger in the middle of the last century; it was afterwards extensively adopted by Corvisart in investigating the diseases of the heart, but its value, like that of all the other branches of auscultation, was not fully appreciated till Laennec made them the subject of his peculiar study. Since his time, its value has been considerably enhanced by the labours of M. Piorry.

Everybody knows that when a hollow body is struck, there is a vibration produced in the air within it, which being communicated through the walls to the external air, produces a ringing sound, whose tone varies with the size of the hollow body, the material of which it is composed, and many other circumstances; but that if the same body be filled with a fluid or a nearly solid substance, no other sound is produced than that which results from the striking together of two solid bodies of the same materials as the wall of the cavity and the substance with which it is struck. On these circumstances the practice of percussion is based. If any part of the body beneath which there is a hollow organ, or one containing air in tubes, be struck, a resonance is produced; if any part which lies over a solid or a fluid be similarly struck, the sound emitted is merely the dull noise of two solid and rather soft bodies.

The modes of employing percussion are various. The simplest and most convenient is to place one finger of the left hand flat upon the part to be examined, and to strike it lightly, but rather sharply, with the ends of the three first fingers of the right hand set close together on the same level. Instruments called pleximeters have been invented by M. Piorry and others: they are composed of small plates of cork, india-rubber, light wood, or ivory, which being held by their edges or by a handle, are placed on the part to be examined, and struck with the fingers, or with a small hammer. Whether the hammer and pleximeter or the fingers are used, care should be taken that the blows are always given with the same or an exactly estimated degree of force, and that they should fall perpendicularly to the surface of the organ to be examined.

Percussion is chiefly employed in the diagnosis of diseases of the lungs, heart, and abdominal organs. [Phthisis; Heart, Diseases of, &c.]

The lungs being chiefly composed of tubes and cells filled with air, there is a certain degree of resonance when the chest over any part of them is struck; but the character of the sound varies somewhat both in intensity and in tone, according to the part of the chest examined, and the thickness and softness or hardness of its walls: in all parts however, when the lungs are healthy, there is resonance. When however the lung is covered by fluid, or has the quantity of air in it lessened by obstruction of the air-tubes, or by deposits of fluid or solid substances in or around the cells, the resonance of the chest directly over the part affected is diminished or entirely lost, and in extreme cases the only sound obtained by percussion is the dull sound of the contact of the fingers with the wall of the chest. When, on the other hand, the air-cells are dilated, and the lungs contain a greater proportion of air than is natural to them, as in emphysema of the lungs, the resonance of the chest is in a corresponding degree increased. The various degrees between perfect dullness, such as occurs when the lung is covered by fluid [Hydrothorax], or rendered solid by inflammation [Lungs, Diseases of], or by tubercular deposition [Phthisis], and the highest degree of resonance in emphysema are numerous, but are of course appreciable only by a very practised ear and hand. To them the evidence they afford is scarcely less valuable than that obtained from the use of the stethoscope, with which the practice of percussion should, in all diseases of the chest, go hand in hand.

In the healthy state, the chest, when struck over the region of the heart, emits a duller sound than that which proceeds from the rest of its walls. In the natural size of the heart this region occupies a space of an inch and a half or two inches square, situated just to the left of the sternum, at the level of the fourth and sixth ribs. When either the heart itself is enlarged, or a quantity of fluid is accumulated in the pericardium, the extent of this less resonant region is increased in a corresponding degree; but the changes of sound which it emits depend greatly on the coincident condition of the lungs, and the extent to which their anterior margins overlap the front of the heart.

By percussion on the abdomen one may obtain information, approximating to truth, of the size of all the solid organs, by the extent of the dullness of sound in their respective regions; and of the degrees of inflation, and even of the nature of the contents of the digestive canal and the peritoneal cavity, whether solid, liquid, or aëriform; but the evidence thus obtained is on the whole less definite in the diseases of the abdominal organs than in those of the heart and lungs.

(M. Piorry, *De la Percussion mediate*, Paris, 1828; Bennett, *Introduction to the Study of Clinical Medicine*, 1860; Weber, *On Auscultation and Percussion*, translated by Cockle, 1854.)

PEREIRIN. An alkaloid of febrifuge qualities, but of uncertain composition, found in the bark of the *Vallesia inedita*.

PERFUMERY, considered as a branch of manufacture, is chiefly chemical in its nature; but its chemistry is of that peculiar kind which relates almost wholly to the *odour* of substances, whether animal, vegetable, or mineral,—whether natural or artificial. The relations of the substances to light and colour, or to solidity and liquidity, are of quite secondary importance; so long as the invisible odour-bearing particles are given off, and conveyed by the air to the organ of smell, all substances may take rank among perfumes—except, of course, such as yield an unpleasant odour. It is generally admitted that perfumes, if pleasant, exercise a cheering and exhilarating influence on the human system, and revive the spirits when fatigued or depressed. The connection between the brain and the organ of smell is too close to allow the former to be quite uninfluenced by anything which affects the latter.

Without touching here upon the physiological or medical relations of perfumes, we shall say a few words concerning their production as a branch of trade. Linnæus divided scents into seven kinds, Touray into five, and De Haller into three. Mr. Rimmel, himself a perfumer, who read a paper on this subject before the Society of Arts in 1860, groups the scents mostly used in perfumery under eighteen kinds, represented by the following types:—rose, jasmine, orange-flower, tuberose, violet, balsam, spice, clove, camphor, sandal, citrine, lavender, mint, aniseed, almond, musk, amber, and fruit flavour. The principal branches of the perfumery trade, connected with these eighteen kinds of scents, are the making of scented soaps, the compounding of perfumes, and the production of numerous minor articles for the toilet. Perfumed soaps are made on the same general principle as common soap, but in smaller quantity, with greater care, and with the addition of certain odoriferous substances. The removal of the excise restrictions has been the cause of much improvement in this art, the perfumer being at liberty to make more varied experiments than were before permitted. The perfumed liquids and pastes are very numerous. The basis of most of them is obtained by treating with alcohol the pomade or oil extracted from flowers. There are also many toilet-waters, such as eau-de-cologne, and the once-famous Hungary water, manufactured chiefly with an alcoholic basis. Lavender-water was formerly distilled with alcohol from fresh flowers; but it is now made more economically by digesting the essential oil in alcohol.

The substances mostly used in the manufacture of perfumery are of *animal* origin, such as musk, civet, and ambergris; *flowers*, such as jasmine, rose, orange-flower, violet, jonquil, narcissus, &c.; *herbs*, such as the leaves and stalks of peppermint, fennel, thyme, marjoram, spike, rosemary, verbena, &c.; *fruits* of the citrine kind, such as orange, lemon, and cedrat; *spices*, such as cassia, cinnamon, cloves, mace, and nutmeg; *woods*, such as sandal-wood, rosewood, cedar-wood, and sassafras; *roots*, such as orris-root and the Indian kus-kus; *seeds*, such as aniseed, dill, and carraway; and *gums*, such as benzoin, styrax, myrrh, camphor, and several balms or balsams. Most of the odoriferous principles are extracted by distillation; but the aroma of flowers is now very often obtained by the agency of fatty bodies. Scented pomades and oils are produced either by maceration or by absorption; the former for the less delicate flowers, and the latter for such as the jasmine and tuberose, which cannot bear a high degree of heat without losing their scent. Mr. Rimmel states that at three towns in the South of France there are no less than 100 firms engaged in obtaining pomades and essential oils from flowers, consuming annually the following quantities and value of flowers:—

1,760,000	lbs.	Orange flowers	£32,000
550,000	,,	Rose flowers	10,000
110,000	,,	Jasmin flowers	6,000
66,000	,,	Violets	7,000
66,000	,,	Cassia	10,000
33,000	,,	Tuberose	3,000

The rose-water, orange-flower-water, scented pomades, and essential oils, obtained from these materials have a value of nearly 300,000*l.* M. Piver, of Paris, adopts a peculiar mode of obtaining the perfumes of plants by bringing a condensed current of air to bear upon the scented particles, and forcing them to combine with a kind of ointment. M. Millon, another French perfumer, extracts the aroma of flowers by means either of ether or sulphuret of carbon, both of which are powerful solvents.

The extent of this manufacture is much larger than is generally supposed. Mr. Rimmel states, from data which he has been able to obtain, that there are 40 manufacturing perfumers in London alone, employing from 20 to 100 hands each; that our imports of essential oils and perfumery materials reaches 200,000*l.* annually; that the retail value of all the perfumery made in the United Kingdom cannot fall far short of 1,000,000*l.* a year; and that there are 80 manufacturing perfumers in Paris, employing 2000 to 3000 hands. Mr. Rimmel gives the names, place of production, and form or condition, of about seventy substances employed by the manufacturing perfumer. The prices affixed to some of these are extraordinary—civet, 1*l.* per oz.; musk, 1*l.* 10*s.* per oz.; ambergris, 2*l.* per oz.; essential oil of *Acacia farnesiana*, 4*l.* per oz.; essential oil of jasmine, 6*l.* per oz.; while attar of roses, in its choicest and most concentrated form, runs up to 12*l.* per oz., or threefold the value of pure gold, weight for weight.

It is worthy of mention, that, although manufacturing perfumers, such as Mr. Rimmel in the paper above adverted to, and Mr. Septimus Piesse, in a recent volume relating to the subject, dwell chiefly on the obtaining of perfumes from flowers, fruits, and other pleasant substances; chemists are well aware of methods by which perfumes can be obtained in a very different way, and from substances which do not at all accord with the names given to the perfumes. Dr. Lyon Playfair, in his lecture on the Results of the Great Exhibition of 1851, said: "A peculiarly fœtid oil, termed fusel oil, is formed in making brandy and whiskey; this fusel oil, distilled with sulphuric acid and acetate of potash, gives the *oil of pears*. The *oil of apples* is made from the same fusel oil, by distillation from sulphuric acid and bichromate of potash. The *oil of pine-apples* is obtained from a product of the action of putrid cheese on sugar; or by making a soap with butter, and distilling it with alcohol and sulphuric acid; and is now largely employed in England in making pine-apple ale. *Oil of grapes* and *oil of cognac*, used to impart the flavour of French cognac to British brandy, are little else than fusel oil. The artificial *oil of bitter almonds*, now so largely employed in perfuming soap, and for flavouring confectionary, is prepared by the action of nitric acid. Many a fair forehead is damped with *eau de millefleurs*, without knowing that its essential ingredient is derived from the drainage of cowhouses." This lecture elicited some objections, on the ground that, although agreeable scents *may* be obtained from offensive substances, it does not follow that they *are* so in practice; but probably the manufacturer who went to such sources would not be likely to own it publicly.

PERIBOLUS. [Temple.]

PERICARDITIS. [Heart, Diseases of the.]

PERIGEE, the point of the moon's orbit in which she is nearest to the earth.

PERIHE'LION, the point of the earth's orbit in which it is nearest to the sun. [Aphelion.]

PERI'METER, the circuit, or bounding line, of a plane figure; a term usually applied to rectilinear figures only, but without any particular reason for the restriction.

PERIOD, a name given to the recurring part of a Circulating Decimal.

PERIODIC ACID. [Iodine.]

PERIODIC FUNCTIONS. The general consideration of periodic magnitude, that is, of magnitude which varies in such manner as to go through stated cycles of changes, each cycle being a reiteration of the preceding one, is the subject of Trigonometry. Though that science derives its name from the measurement of triangles (as geometry does from that of the earth), its resources have been cultivated and its methods expanded until no definition short of the preceding will express its object or convey an idea of its powers.

In the article cited will therefore be explained the mode of measurement applied to periodic magnitude: the present one is intended for nothing more than to point out a peculiarity of some classes of algebraic functions which has procured for them the name of *periodic functions*.

The calculus of Functions considers only forms, and the operations necessary to convert one given form into another, or to satisfy equations in which some forms of operation are unknown. Periodic functions are those which, performed any given number of times on a variable, reproduce the simple variable itself. Thus $1 - x$ and $-x$ are periodic functions of the second order, since

$$1 - (1 - x) = x, \quad -(-x) = x.$$

Again, $1 : (1 - x)$ is a periodic function of the third order, since, if we begin with x, and write $1 : (1 - x)$ for x three times in succession, we end with x also—

$$x, \quad \frac{1}{1-x}, \quad \frac{x-1}{x}, \quad x.$$

Periodic functions are remarkable in the calculus of functions for the simplicity with which questions connected with them can be solved, when compared with the difficulty of solution of cases in which non-periodic functions enter. Their principal properties are here briefly pointed out: for further information, consult Babbage's 'Examples of Functional Equations' (appended to Peacock's 'Examples'), or the article on the Calculus of Functions contained in the 'Encyclopædia Metropolitana,' where further references will be found.

Let ϕx be a function of x; abbreviate $\phi(\phi x)$ into $\phi^2 x$; $\phi(\phi^2 x)$ into $\phi^3 x$, &c.: then, if ϕ be a periodic function of the nth order, $\phi^n x = x$.

Let r be one of the nth roots of unity, then rx is the simplest periodic function of the nth order; but very simple ones of the form $(1 + bx) : (c - kx)$ may be obtained by making

$$k = \frac{b^2 - 2bc\cos\theta + c^2}{2(1 + \cos\theta)}$$

where θ means the nth part of any multiple of four right angles. For instance, if $n = 4$, θ may $= 90°$, and $\cos\theta = 0$, whence $k = (b^2 + c^2) : 2$; whence

$$\frac{2 + 2bx}{2c - (b^2 + c^2)x}$$

is a periodic function of the fourth order.

Let Θx be any function of x whatsoever, and $\Theta^{-1}x$ its Inverse function, so that $\Theta\Theta^{-1}x = x$; then if ϕx be a periodic function, $\Theta\phi\Theta^{-1}x$ is also periodic. Thus $1 - x$ being periodic of the second order, so are $\log(1 - \epsilon^x)$, $\sqrt{(1 - x^2)}$, $\sin^{-1}(1 - \sin x)$, &c. &c.

Let $\Theta\phi\Theta^{-1}x$ be called a derivative of ϕx; then if ϕx and ψx be two periodic functions of the nth order, either can in an infinite number of ways be made a derivative of the other. Thus one of the ways in which $1 : x$ is a derivative of $-x$ is $\epsilon^{-\log x}$. Let $1, r, r^2, \ldots . r^{n-1}$ be all the n roots of unity, let P_0 be any function of x and y, and let P_1 be the same function of ϕx and ψy, P_2 of $\phi^2 x$ and $\psi^2 y$, &c. From the equation

$$P_0 + rP_1 + r^2 P_2 + \ldots . + r^{n-1} P_{n-1} = 0,$$

find y in terms of x; say $y = \Theta x$. Then will $\psi y = \Theta\phi x$, or $\psi x = \Theta\phi\Theta^{-1}x$; that is, ψx is expressed as a derivative of ϕx.

For example, let $\phi x = -x$, $\psi x = 1 - x$, be the periodic functions, of the second order; then $r = -1$. Let $P_0 = ax + by$, then the preceding equation becomes

$$ax + by + (-1)(-ax + b\overline{1 - y}) = 0;$$

$$\text{or } y = \Theta x = \frac{b - 2ax}{2b}, \quad \Theta^{-1}x = \frac{b - 2by}{2a}$$

$$\Theta\phi\Theta^{-1}x = \frac{b - 2a\left\{-(b - 2bx) : 2a\right\}}{2b} = 1 - x.$$

The periodic functions, as before observed, are those whose relations are most easily obtained. For example, let αx, βx, γx, be given functions of x, and ϕx an unknown function, to be determined by the equation

$$\phi x = \beta x + \gamma x \phi \alpha x.$$

If αx be not periodic, there are two difficulties in the way, each most frequently insuperable: first, the determination of some one solution of this equation; secondly, the determination of the Invariable function of this equation, or the solution of $\psi\alpha x = \psi x$. But when αx is periodic, both difficulties can be overcome and a general solution given. Say $\alpha^n x = x$, then ψx is any symmetrical function of x, αx, $\alpha^2 x, \ldots . \alpha^{n-1}x$; and if B_0, B_1, &c., be βx, $\beta\alpha x$, &c., and $C_0\, C_1$, &c., be γx, $\gamma\alpha x$, &c., the general solution divides into two cases, in the first of which the solution does not depend on the invariable function.

The most general case gives

$$\phi x = \frac{B_0 + C_0 B_1 + C_0 C_1 B_2 + \ldots + C_0 C_1 \ldots C_{n-2} B_{n-1}}{1 - C_0 C_1 C_2 \ldots . C_{n-1}}$$

In this case the preceding is the most complete and only solution. But if C_0 and B_0, &c., be such that the numerator and denominator of the preceding both vanish, the general solution is

$$\begin{aligned} n\phi x = {} & (n-1) B_0 + (n-2) C_0 B_1 + (n-3) C_0 C_1 B_2 \\ & + \ldots . + C_0 C_1 C_2 \ldots C_{n-3} B_{n-2} \\ & + (1 + C_0 + C_0 C_1 + \ldots . + C_0 C_1 \ldots C_{n-2})\, \psi x. \end{aligned}$$

For demonstration and extension, see the article cited in the 'Encyc. Metrop.,' §§ 192-198, and 235.

PERIODS OF REVOLUTION. In the present article we simply describe the names, commencements, lengths, and uses of those periods which it is most requisite the reader should find distinctly explained in a work of reference, premising some explanation of the way in which comparison of different periods gives new periods.

By a period we mean a definite portion of time, beginning from a given *epoch*, or *æra*,* which, being repeated again and again, will serve to divide all time subsequent to the epoch (or precedent, if the repetitions be also carried backwards from the epoch) into equal parts, for the purposes of common reckoning and historical chronology. A period is then a finite portion of time used for measurement, just as a foot or mile is used for measurement of length.

Periods may be divided into natural and artificial; the former immediately suggested by some recurrence of astronomical phenomena; the latter arbitrarily chosen. Since, however, time cannot be preserved and handed down as if it were material, it is natural that the knowledge of artificial periods should be preserved by representing the number of natural periods which they contain; nor is it to be supposed that artificial periods were ever invented in a perfectly arbitrary manner, or were indeed ever anything more than convenient collections of natural periods.

When one period is contained an exact number of times in another, each recommencement of the larger one is also a recommencement of the smaller one; thus, the day being exactly twenty-four hours, if any one day begin at the beginning of an hour, all days will do the same. But if the smaller period be not a measure of the larger, a longer period may be imagined, which in this article we shall call a *cycle*, consisting of the interval between the two nearest moments at which the smaller and larger periods begin together. Thus, a week of seven days and a month of thirty days give a cycle of seven months or thirty weeks, these two periods being equal. If, however, the two periods can be measured by a larger number of days, the cycle may be made smaller; thus, a month of 30 days and a year of 365 days, or a month of 6 times five days, and a year of 73 times five days, would give a cycle of 6 × 73 times five days, that is of 6 years or 73 months.

When two natural periods are expressed by complicated fractions of days, the method explained in Fractions, Continued, will serve to show nearly how many of one period make up an exact number of the other. Thus the tropical, or common year being 365·24224 days, and the lunation being 29·53059 days, both approximate, it appears that 36,524,224 lunar months would be 2,953,059 years nearly. To reduce this long cycle to others more convenient for use, and as accurate as the number of figures employed will permit, proceed as in the article cited with the fraction

$$\frac{2{,}953{,}059}{36{,}524{,}224}$$

The quotients obtained are 12, 2, 1, 2, 1, 1, 17, &c., at which we stop, because the appearance of so large a quotient as 17, shows that the result of the preceding quotients is extremely near. The successive approximations derived from the first six quotients are—

$$\frac{1}{12} \quad \frac{2}{25} \quad \frac{3}{37} \quad \frac{8}{99} \quad \frac{11}{136} \quad \frac{19}{235}$$

Or 235 lunations make 19 years very nearly.

The period in which all others are expressed is the day, which is not, as many suppose, the simple time of revolution of the earth, but [Day] the average time between noon and noon. To distinguish it from other days it is called the *mean solar* day.

The year, or the time between two vernal equinoxes, is not a uniform period, nor does the average of one long period give *precisely* the same as another. [Year.] For chronological purposes, however, it is useless to take account of this variation, and 365·2422414 days, the year of astronomers in our day, may be considered as more than sufficiently exact for any time. In fact the year is made to consist, in the long run, of 365·2425 days, and a cycle of 400 years is necessary to the complete explanation of this fraction. Supposing the years from A.D. 2001 to A.D. 2400, both inclusive, each fourth year is leap-year, beginning with 2004, except only 2100, 2200, and 2300, which gives in the 400 years 365 days to each year, and 97 intercalated days; while adding 97 days to 400 years, adds on the average 97-400ths or ·2425 of a day, to each year. As it is of considerable importance distinctly to comprehend an intercalated cycle, that is one in which fractions are disregarded until they amount to a unit, when they are corrected, to use a common phrase, in the lump, we put down the effect of the correction which is made in the year 1840, being leap-year. In 1836, immediately after the last intercalation was made, the sun was in the vernal equinox at about 39 minutes after 1 P.M. on the 20th of March, and the equinoxes then took place as follows :—

---

* These terms are used synonymously by most chronologers: but some mean by *æra* the whole of the time which is measured from the *epoch*. The ear of the reader will perhaps be familiar with both of the phrases, "the 5th century *of* the Christian æra," and "the 5th century *after* the Christian æra."

1836	Sun in equinox	at $1^h\ 39^m$ P.M.	March 20
1837	,,	at $7^h\ 23^m$ P.M.	March 20
1838	,,	at $1^h\ 18^m$ A.M.	*March* 21
1839	,,	at $7^h\ 1^m$ A.M.	*March* 21
1840	,,	at $0^h\ 41^m$ P.M.	March 20

The intercalation of 1840 (but for which the sun would have come on the equinox at 41 minutes past noon on the *twenty-first*) has overdone the correction, bringing the equinox nearer to noon than in 1836 by 58 minutes. Now this over-correction of nearly an hour in four years is set nearly right by leaving out the correction three times in 400 years; a provision the necessity of which may be imagined, though its exactness cannot be appreciated from the preceding rough calculation.

The Gregorian year, therefore (or the year in the Gregorian reformation of the kalendar), is a portion of a cycle of 400 years of 365 days, 97 of which have an additional day. [KALENDAR.] The Julian year, in use before the Gregorian reformation, is a portion of a cycle of 4 years of 365 days, one of which has an additional day. Without a perfect comprehension of the manner in which the incommensurability of the year and day is remedied, no progress can be made in the understanding of the nature and use of chronological periods.

An Æra means either the commencement of an indefinite reckoning, or of a succession of periods. In the article ÆRA will be found the complete description of the most important æras; but as it often happens that for reference the mere time of an obscure or uncommon æra is wanted without explanation, we subjoin an extensive list, merely giving the leading words, and the date A.D. or B.C. of the vulgar Christian æra. It is to be remembered that the birth of Jesus Christ is supposed to have taken place in the fourth year B.C. of this common æra. The figures following the years refer to months and days: thus A.D. 729 . 6 . 13 would stand for [*] the 13th day of June, A.D. 729. We do not mean to say that the events in the following list did take place in the years, far less in the months, or on the days, which are set down: but only that those who used them as æras, took them as having happened in those years, months, and days. Thus the death of Alexander, according to Clinton, took place in B.C. 323, which is most likely to be right; but if those who afterwards made an æra of this death, reckoned from the 12th of November B.C. 324, that day is the æra, whether the event happened then or not.

Gregorian reformation, or new style		A.D. 1582
English adoption of the Gregorian reformation		A.D. 1752

Among the various sources of confusion may be noticed—1, an old practice of astronomers, who call the year immediately preceding and following the vulgar æra, not 1 but 0, as calculation requires; 2, the discrepancies arising from different times of beginning the year. The most important of these to the English reader is the following: Before the change of style in 1752, and from the 14th century to that time, the legal and ecclesiastical year began on the 25th of March, though it was very common in writings, &c., to begin it on the 1st of January. Hence January, February, and twenty-four days of March, were in one year, according to lawyers, &c.; and in another according to others. Thus the Revolution, so called, of 1688, took place in the February of that legal year, or, as we should now say, February, 1689. It is frequently written thus: February, $168\frac{8}{9}$, or February, 1688-9. Thus, King Charles was beheaded January 30, $164\frac{8}{9}$, or January 30, 1648-9.

We now come to the artificial periods which are of most use in chronological researches: these are—

1. The cycle of the sun, or more properly the cycle of Sundays.
2. The cycle of the moon, or of nineteen years, or of the Golden number, or of the Primes, or the Metonic cycle with its æra altered. [METON, in BIOG. DIV.]
3. The cycle of indictions.
4. The Paschal cycle.
5. The Julian period.

1. The cycle of the sun is a period of 28 years, compounded of 7 and 4, the number of days in a week, and the number of years in the interval of two leap-years. This, *in the old style*, makes the Sundays return to the same days of the year; every year of the cycle being in this respect exactly the same as the same year of the preceding cycle. Thus, the year A.D. 1 being the tenth in its solar cycle, and the DOMINICAL LETTER being for that year B, or the 2nd of January being Sunday, the 2nd of January was also Sunday in the year A.D. (1+28), or A.D. 29, also in A.D. (29+28), or A.D. 57, &c.

The series of dominical letters for the complete solar cycle is as follows: attached to each dominical letter is what is called the *concurrent* of the year, meaning the number of days elapsed over and above a complete number of weeks, from the beginning of the cycle (not including the first day) to that of the year in question, the concurrent being written 7 where 0 would perhaps have been better.

1	GF	1	8	E	2	15	C	4	22	A	6
2	E	2	9	DC	4	16	B	5	23	G	7
3	D	3	10	B	5	17	AG	7	24	F	1
4	C	4	11	A	6	18	F	1	25	ED	3
5	BA	6	12	G	7	19	E	2	26	C	4
6	G	7	13	FE	2	20	D	3	27	B	5
7	F	1	14	D	3	21	CB	5	28	A	6

Connected with this table is one of what were called solar *regulars* (regulators would have been the modern term), one for each month, as follows :—

Jan.	2	April	1	July	1	Oct.	2
Feb.	5	May	3	Aug.	4	Nov.	5
March	5	June	6	Sept.	7	Dec.	7

The table given in DOMINICAL LETTER would save some of the following process, which however it is better to give.

Old Style.—To find the part of the solar cycle in which any given year is found. If the year be A.D., add 9 and divide by 28; the remainder (or 28 if the remainder be 0) is the year of the solar cycle required. But for a year B.C., deduct 10 from the date, and divide by 28; the remainder deducted from 28 gives the year. The dominical letter and concurrent are then taken from the preceding table. And to find on what day of the week the first day of any month fell, to the concurrent of the year add the regular of the month, the sum (diminished by 7, if it can be done) shows the day, 1 being Sunday, 2 Monday, &c. (But in leap-year one day later must be taken for every month after February.) Thus to find the day on which the æra of the Hegira fell, or July 16, 622 A.D., 622+9 or 631 divided by 28 gives the remainder 15, which is the year of the cycle. The concurrent is 4, which added to the regular of July 1, gives 5, or Thursday for the 1st July, and Friday for the 16th; whence Friday is the day required.

The perpetuity of the solar cycle, in the connection of its numbers with the dominical letters, &c., is destroyed by the new style, in which a similar cycle of no less than 2800 years exists. Up to the end of this century, however, the cycle of 28 years, as it now exists, will remain undisturbed,[*] and it may therefore be worth while to give the years of the solar cycle answering to the decads of the century, and the table o dominical letters, concurrents, and regulars :—

---

[*] There is some incorrectness, but great convenience in this. Astronomers now sometimes use such a notation as 1859·61, not to denote 1859 years *and* 61-100ths of a year, but the moment at which 61-100ths of the 1859th year have elapsed.

[*] Since A.D. 1900 is not leap-year, the whole cycle will then be overthrown, but since A.D. 2000 is leap-year, it may be reconstructed so as to last till 2100.

1801, 18	1820, 9	1840, 1	1860, 21	1880, 13
1810, 27	1830, 19	1850, 11	1870, 3	1890, 23

1	ED	1	8	C	2	15	A	4	22	F	6

Jan.	3	April	2	July	2	Oct.	3
Feb.	6	May	4	Aug.	5	Nov.	6
March	6	June	7	Sept.	1	Dec.	1

To find the 1st of April, 1836 : the year is 25 of the cycle, and leap-year, and the concurrent 3 added to 2, the regular of April, with 1 allowed for leap-year, gives 6, or Friday.

There are many *perpetual almanacs*, as they are called, by which such questions as the preceding can be solved by reference, without calculation. But when the almanac of a particular year is wanted in totality, there must be thirty-five distinct almanacs set out, to meet every possible location of Easter-day, with an index by which the year is to show which almanac to turn up. Several of the monastic orders constructed almanacs for themselves on this principle, with their own peculiar days of ceremony duly entered : and M. Francœur published a general one at Paris in 1842. On this hint Mr. De Morgan constructed his 'Book of Almanacs,' 1851, in which the *whole almanac* of any year, the moon * excepted, is turned up at once, whether in old or new style.

2. The cycle of the moon is that of 19 years, which is very nearly 235 complete lunations, as follows : the 235 mean lunations of 29·53059 days each make 6939·69 days, while 19 years of 365 days each give 6935 days, and, allowing 4¾ days for leap-years, 6939·75 days. Hence 235 lunations fall short of 19 Julian years by ·06 of a day, or one day in about 317 years. During a period of 300 years, and as far as the mean place of the moon is concerned [EASTER], the new and full moons of the cycle of nineteen years would fall on the same days. On the assumption of 235 lunations exactly corresponding to 19 years, all the rules for finding Easter are founded ; and in the steadiness with which this false assumption was held to, lies the value of Easter in chronology. If the astronomers had been allowed to vary Easter according to the latest improvements in determining the moon's place, the chronology of the details of the different years of the middle ages, confused as it sometimes is, would rarely have been anything but confusion ; in chronological reckoning nothing is of any importance compared with keeping to one unvaried rule ; and the reformation (so called) of the calendar was, in our opinion, anything but an improvement.

Chronologists have two cycles of nineteen years each, the first of which is the cycle of nineteen years (so called), or of the golden number, and the second, which begins three years later, they call the lunar cycle. These of course only differ in their time of commencement, the year 4 of the first cycle being always 1 of the second. To show the manner in which accuracy was attempted, it is worth while to quote the date of one charter, from the 'Art de vérifier les Dates,' particularly as all the dates are quite exact : "Acta sunt hæc, anno ab incarnatione Domini MCIX., indictione II., epacta XVII., concurrente IV., cyclus lunaris V., cyclus decemnovennalis VIII., regularis paschæ IV., terminus paschalis XIIII. kal. Maii, dies paschalis VII. kal. Maii, lunæ ipsius (diei paschæ) XXI."

After what has been said on EASTER, there is no occasion to enter on that subject here.

The epact of the year is usually stated as being the moon's age at the beginning of the year : this is a correct definition as to the epact of the Gregorian calendar, but not so as to that which preceded. The epact of the old calendar is a number depending on the year in such manner that the epact of the year, increased by what was called the lunar regular of any month, gives (with deduction of 29, if necessary) the age of the moon on the first day of that month ; so that the age of the moon at the beginning of the year is the epact, together with the regular of January. Thus the epact of every year may be increased or diminished at pleasure, provided all the numbers in the table of regulars be as much diminished or increased ; and different tables of epacts will be found in different works, the difference being of course compensated in the regulars, or else in the rule for applying them. The epact of each year of the cycle of 19 years must be 11 more than that of the preceding, abating 30 as fast as it arises ; this must be the case in every table, and the most common table of epacts gives 29 as the epact of the first year of the cycle, 10 as that of the second, 21 as that of the third, &c. Corresponding to this, 9 is the regular of January, 10 of February, &c. It is not worth while to give the table, not only because it is now useless, even for old chronology, but because it fails for those years of the decemnovennal cycle in which two full moons come in the same month.

Again, the annual regular, or the regular cited in charters (as in our previous quotation, where it is called the paschal regular), is neither the solar regular described in the former part of this article, nor the lunar regular just mentioned, but a third regular belonging to the whole year, and which, added to the concurrent previously described, gave (7 being abated, if necessary) the last day of the moon preceding the paschal moon. Thus, A.D. 874, the concurrent being 4 and the annual regular 5, their sum 9 diminished by 7, or 2, gives Monday as the last day of the ante-paschal moon.

The paschal term (terminus paschalis) mentioned in the quotation, meant simply the fourteenth day of the paschal moon.

3. The Indiction was an edict of the Roman emperors, fixing the tribute ; and as one such edict was supposed to have appeared every fifteen years, years were naturally reckoned according to their distance from the year of indiction. There is doubt about the first origin of indictions, about their meaning and their earliest date : all we have here to do with is the fact, that from Athanasius downwards, they were more or less employed by ecclesiastical writers in describing epochs. The popes afterwards adopted this mode of dating, and the common indiction * found in chronological tables begins so that A.D. 313 is the first year of the first cycle of indiction, each cycle containing 15 years. At this rate, A.D. 1 was the fourth year of an imaginary preceding indiction, and the remainder of three more than the date of any year divided by 15 will give its position in its cycle of indiction. Thus 1239, increased by 3 and divided by 15, gives the remainder 12, or A.D. 1239 is the twelfth year of a cycle of indiction.

4. The paschal cycle is one composed of 28 and 19 years, or 532 years, during which time the cycles of the sun and of 19 years run through all their combinations, and recommence them again. According to the old system, then, this is the cycle of Easter Days, which begin again in the same order when it is finished : A.D. 1 was the second year of the first paschal cycle, being also 2 of the cycle of 19 years, and 10 of its solar cycle. The paschal cycle of the Gregorian calendar would be 53,200 years.

5. The Julian † period was imagined by Joseph Scaliger, and is a combination of the solar cycle, the cycle of 19 years, and that of indictions. Now 28 × 19 × 15 gives 7980 years, which is the length of the period in question. It was made to begin at a year B.C., which was the first year of each cycle—namely, B.C. 4713 years. Hence, subtract any year B.C. from 4714, or add any year A.D. to 4713, and you have the year of the Julian period answering to the date used. The advantage (if it be one) of this period is, that by dividing the year in it by 28, 19, and 15, the remainders show the years of the different cycles belonging to the Julian date used, remembering when the remainder is nothing to substitute the divisor instead.

For the history of periods not absolutely used in chronology, see their several names, such as Metonic Cycle, under METON, in BIOG. DIV., SAROS, SOTHIAC PERIOD, &c., &c.

Astronomical periods, actually existing in nature, may be divided into *days*, connected with the rotations of planets round their axes ; *months*, connected with the rotation of satellites round their primaries ; *years*, connected with the rotations of primary planets round the sun ; and *secular* periods, connected with slow changes of the elements of orbits. The most convenient period of measurement is the civil or mean solar day at the earth, being the average interval between noon and noon. [SYNODIC REVOLUTION.]

This period being divided into hours, &c., the actual rotation of the earth is $23^h\ 56^m\ 4^s{\cdot}09$, and is called the sidereal day. The average interval between two transits of the moon over the meridian is $24^h\ 50^m\ 28^s{\cdot}32$, which might be called the mean tide-day. The rotation of the moon is the time of her revolution round the earth [MOON]; and the rotations of the planets are as follows (in *sidereal* time) so as to make 24^h the rotation of the earth :—

	d.	h.	m.		h.	m.
Sun . . .	25	8		Jupiter . . .	9	56
Mercury . .		24	5½	Saturn . . .	10	29½
Venus . .		23	21	Uranus unknown.		
Earth . .		24		Neptune unknown.		
Mars . .		24	38			

Various months are described in the article MOON, the only ones here necessary to cite being the one already used, of $29^d\ 12^h\ 44^m\ 2^s{\cdot}9$, or $29^d{\cdot}53059$, the average interval from new moon to new moon, and

---

* Means are added of finding the new or full moons of any year, within a day, without any calculation : and also means of calculation to find them within two hours.

* The first indiction of Constantine is variously stated to have been A.D. 312, 313, 314, and 315.

† Some say that the name was in honour of his father, Julius Scaliger ; some that it was called from the Julian year. The discrepancy need never have arisen, for Joseph Scaliger says, "Julianam vocavimus quia ad annum Julianum accommodata." ('De emend. temp.,' ed. 1629, Geneve, p. 361.) The false account was probably fostered by the great honour in which Joseph Scaliger held his father, whose son he frequently called himself in his title-pages. But this name referred to a very different person. The treatise just quoted first appeared in 1583, just after the reformation of the calendar : and Scaliger was a warm opponent of Clavius in this matter. He stood up for the old Julian year. In the very first mention of the period which occurs (Preface, p. ii.), he says, "Qui anno Juliano, quæ omnium formarum temporibus est convenientissima, uti volet, is . . . . componet elegantissimam periodum annorum 7980, . . ."

27^{d} 7^{h} 43^{m} $11^{s}{\cdot}5$, or $27^{d}{\cdot}32166$, the actual time of revolution of the moon in the heavens. The satellites of Jupiter, Saturn, and Uranus have revolutions round their primaries as follows:—

		d.	h.	m.		d.
Jupiter's	First S.	1	18	28	or	1·7691
	Second S.	3	13	14		3·5518
	Third S.	7	3	43		7·1546
	Fourth S.	16	16	32		16·6888
Saturn's	Ring	0	10	32		0·4370
	First S.	0	22	38		0·9427
	Second S.	1	8	53		1·3702
	Third S.	1	21	18		1·8878
	Fourth S.	2	17	45		2·7395
	Fifth S.	4	12	25		4·5175
	Sixth S.	15	22	41		15·9453
	Seventh* S.	21	7	8		21·2972
	Eighth S.	79	7	55		79·3296

The following are the old statements relative to the satellites of Uranus, as given by William Herschel. Such an article as this is not the place to enter upon the doubts relative to these bodies.

		d.	h.	m.	d.
Uranus's	First S.	5	21	25	5·8926
	Second S.	8	16	58	8·7068
	Third S.	10	23	4	10·9611
	Fourth S.	13	10	56	13·4559
	Fifth S.	38	1	48	38·0750
	Sixth S.	107	16	40	107·6944
Neptune's	Satellite	5	21	3	5·8769

The civil year is the *tropical* year, or the time of revolution of the sun from the vernal equinox to the same again. Owing to the motion of the equinox [PRECESSION], this year, or 365^{d} 5^{h} 48^{m} $49^{s}{\cdot}7$, or $365^{d}{\cdot}2422414$, is shorter than the actual revolution of the earth round the sun, which is 365^{d} 6^{h} 9^{m} $9^{s}{\cdot}6$, or $365^{d}{\cdot}2563612$. Again, the *anomalistic* year, being that in which the earth moves from its nearest point to the sun to the same again, is 365^{d} 6^{h} 13^{m} $49^{s}{\cdot}3$, or $365^{d}{\cdot}2595981$. The following is the list of the actual revolutions of the planets round the sun, each to a tenth of a day, including the verified periodic comets, so far as their times are known:—

	Days.		Days.
Mercury	88·0	De Vico's Comet	1993·0
Venus	224·7	Brorsen's Comet	2042·0
Earth	365·3	Biela's Comet	2394·0
Mars	687·0	Faye's Comet	2718·0
Encke's Comet	1210·0	Jupiter	4332·6
Vesta	1325·7	Saturn	10759·2
Juno	1592·7	Uranus	30686·8
Ceres	1681·4	Halley's Comet	75 to 76 years.
Pallas	1686·5		

Of secular periods, the most important are, the revolution of the moon's node, in 18·6 years; of the earth's perihelion, from the vernal equinox to the vernal equinox again (the latter also moving), or 21,000 years, and the revolution of the equinoxes themselves, in 26,000 years.

PERIŒCI (περίοικοι), an old astronomical term for those who have the same latitude, but opposite longitudes.

PERIPATETICS (περιπατητικοί) is the name given to an ancient philosophical sect. It was so designated from the circumstance of its founder, Aristotle, being accustomed to deliver his doctrines while walking in the grove of the Lyceum in the suburbs of Athens. [ARISTOTLE, in BIOG. DIV.] There is scarcely any department of human knowledge of which the writings of Aristotle do not treat. It would far exceed the limits of this article to give a full detail of his opinions. Such of them only as characterised the school which he originated can be referred to, and even these must be briefly noticed. They have relation chiefly to his general physical and metaphysical principles. To his system of logic, with the additions subsequently made to it by his disciples, it is unnecessary particularly to advert. [ORGANON.]

Previous to Aristotle's time it was commonly supposed by those who had speculated respecting the origin of the universe, that there is an eternal substance from which bodies are made, and on which forms are impressed, and to which the name of matter was assigned. This matter was understood to have been always in motion, to consist of indefinitely small particles, and to have been collected and united in bodies by the agency of an intelligent principle. It was further supposed that the original particles had certain properties by which they differed from each other, and by which the constitution of the bodies which they composed was determined. Empedocles and others taught that there were four primary elements, which are the bases of all corporeal forms; Anaxagoras and his followers maintained that bodies exactly represent the form of each of their constituent particles: while Plato held that essential forms have an actual existence in the divinity, and that by the union of these with matter the formation of bodies is effected.

Rejecting all these theories, Aristotle assumed the underived and independent existence of two opposite principles. But since such principles by their contrariety would destroy each other, the existence of a third was requisite. These he conceived to be matter, form, and privation, the first two being the constituent principles of things, and the last being accidentally connected with them. The first matter was imagined to be entirely destitute of all qualities, to exist potentially, and to be the subject in which forms are made to inhere. Form he explained to be the essence of a thing, or that which constitutes it what it is. How the first matter and form were brought into union so as to produce bodies does not appear; unless nature, the meaning of which term, as employed by Aristotle, it is not easy to apprehend, accomplishes the union.

Aristotle distinguished causes into the material, the formal, the efficient, and the final; the first being that of which things are made, the second that by which they are what they are, the third that by the agency of which anything is produced, and the last the design of its production. Having thus provided for the existence of substances generally, Aristotle divides them into three classes: the eternal, as the heavens; the perishable, as the bodies of animals; and the immutable nature, or prime mover, as it was otherwise called. This prime mover, which occupies the place of God in his system, was considered to be an eternal, incorporeal, and simple intelligence, and the original source of all motion, being itself unmoved. Its agency extended directly to the first celestial sphere, and mediately through similar inferior intelligences to the lower spheres, and by them to the universe at large.

Sensible bodies were divided by Aristotle into simple and compound; simple bodies being those elements which result from the combination of primary matter and form, and compound bodies those which proceed from elementary combinations. In bodies thus distinguished there are certain active and passive qualities, which constitute their specific difference, and by which they mutually tend to transform each other into their own nature. In consequence of the action of the first mover, whether direct or indirect, on matter, there is a continual succession of dissolution and reproduction; reproduction taking place when the essence of a body is entirely changed, and only an augmentation or diminution when its accidental qualities undergo mutation.

Such is an imperfect sketch of Aristotle's general doctrine of physics. His opinions respecting man may be shortly summed up. The principles of the soul and of animal life he thought to be identical, giving them the common designation of entelecheia (ἐντελέχεια), or perfect energy. The faculties of the soul he considered to be, the nutritive, by which life is produced and preserved; the sensitive, by which we perceive and feel; and the rational, by which we understand. The sensitive faculty takes cognisance of external objects by means of its organs, which are adapted to produce the various sensations of sight, hearing, &c. The senses receive forms or sensible species in the same manner as wax receives the impression of a seal. Fancy is the perception which results from the immediate operation of the senses; while memory is derived from fancy, and is the effect of images formed in the soul by the senses. The intellectual or rational faculty is of two kinds, either active or passive. Passive intellect receives the form of things, and is the seat of species. Active intellect is either simple or complex: simple when it engages in the close apprehension of its object; complex when it combines simple conceptions so as to engender belief. Intellectual action is theoretical when it contemplates what is simply true or false, and practical when it determines what is good or evil, and thus gives rise to volitions.

Whether Aristotle believed in the immortality of the soul or not, has not been clearly ascertained. From his notion that the soul is a power externally transmitted into the body, it has been inferred that he held it to be mortal, and that it ceased to have a separate existence after the dissolution of the body.

Aristotle's school in the Lyceum was continued for about twelve years. In consequence of the hostility of his enemies, who accused him of propagating impious tenets, he retired, soon after the death of Alexander, to Chalcis, where he died. Before withdrawing from his public labours however he appointed Theophrastus, of Eresus in Lesbos, his successor in the chair. The opinions of Theophrastus differed in some respects from those of Aristotle, but he taught with great success, and was attended by about two thousand scholars. He was followed consecutively by Straton of Lampsacus, Lycon, or Glycon of Troas, Ariston of Ceos, and Critolaus the Lycian. With Diodorus of Tyre, who came immediately after Critolaus, the uninterrupted succession of the Peripatetic school terminated, about the 140th Olympiad. Among the early followers of the Stagirite, who did not fill the chair, were several eminent philosophers. The most distinguished of these were Dicæarchus, a Messenian, Eudemus of Rhodes, and Demetrius Phalereus.

The Peripatetic doctrines were introduced into Rome in common with the other branches of the Greek philosophy by the embassy of Critolaus, Carneades, and Diogenes, but were little known till the time of Sylla. Tyrannion, an eminent grammarian, and Andronicus Rhodius, were the first who brought the writings of Aristotle and Theophrastus into notice. The obscurity of Aristotle's writings tended much to hinder the success of his philosophy, but it nevertheless soon gained a considerable number of supporters. During the reign of the Cæsars, it acquired all its ancient influence; and till the time of Ammonius, the preceptor of Plutarch, was taught with great purity. After that it was divided into two sects, consisting respectively of those who wished to adhere strictly to Aristotle, and those who were disposed to amalgamate his doctrines with those of other schools. Julius Cæsar and Augustus patronised the Peripatetic philosophy. Under Tiberius, Caligula, and Claudius, its adherents, in common with those of other sects, were either banished or obliged to remain silent on the subject of their peculiar tenets. This was the case also during the greater part of the reign of Nero, although during the early part of it philosophy was favoured. The chief Peripatetics in the first century of the Roman empire were Sosigenes of Egypt, who wrote a commentary on Aristotle's treatise 'De Cœlo,' Boethus of Sidon, who is mentioned by Strabo as having been his fellow-student in the Aristotelian philosophy, and Nicolaus of Damascus in Syria.

---

* Discovered in 1848 by Lassell and Bond.

Ammonius the Peripatetic made great exertions to extend the authority of Aristotle; but about his time the Platonists began to study his writings, and prepared the way for the establishment of the Eclectic Peripatetics under Ammonius Saccas, who flourished about a century subsequent to Ammonius the Peripatetic. Even after this period however some were still found who adhered exclusively to Aristotle. The most celebrated of these was Alexander of Aphrodisias, who was a public professor of the Peripatetic philosophy, under Septimius Severus, in Alexandria or in Athens. Many of the Eclectic Aristotelians wrote commentaries on his works, some of which are still extant. The principal of these writers were Themistius, who flourished during the reigns of Constantius and Theodosius the Great; Olympiodorus, who lived about a century later: and Simplicius Cilix, in the time of the emperor Justinian.

After this period, philosophy in general languished. But in that mixture of ancient opinions with theological dogmas which constituted the philosophy of the middle age, the system of Aristotle undoubtedly predominated. About the 12th century it had many adherents among the Saracens and Jews, particularly in Spain; and at the same period also it began to be diligently studied, though not without much opposition, among the ecclesiastics of the Christian church. Out of this latter circumstance gradually arose the Scholastic philosophy, which took its tone and complexion from the writings of Aristotle, and which continued long to perplex the minds of men with its frivolous though subtile speculations. The authority of Aristotle received a severe shock at the Reformation, but it survived the fall of the Scholastic system. His opinions were patronised by the Roman Catholic church, on account of their supposed favourable bearing on certain doctrines of faith; and although Luther and others of the Reformers determinedly opposed them, they were maintained by such men as Melancthon, who himself commented on certain portions of the works of the Stagirite. Many individuals distinguished for their genius and learning exerted themselves to revive the Peripatetic philosophy in its primitive purity, nor did it cease to have numerous illustrious supporters until the time of Bacon, Grotius, and Des Cartes.

PERI'PHERY, the Greek word for circumference; term applied both to rectilinear and curvilinear figures.

PERIPNEUMONY. [Lungs, Diseases of the.]

PERIPTERAL or PERIPTEROS. [Temple.]

PERI'SCII (whose shadows move round). In those latitudes which are high enough to have the sun for twenty-four hours together, the shadows make complete revolutions; whence the inhabitants may be called Periscii (Περίσκιοι).

PERISCOPIC SPECTACLES. [Spectacles.]

PERITONITIS is an inflammation of the peritoneum. It may exist either as an acute or as a chronic disease. The chief symptoms of the acute form are pain, swelling, and tenderness of the abdomen, accompanied with fever and a frequent, small, and hard pulse. The pain in peritonitis is usually much more severe than that of any other inflammatory disease of the intestines or other abdominal organs. It is acute and cutting, and sometimes occurs in paroxysms; it is generally diffused, but occasionally it is almost confined to a single part of the abdomen; but its most distinguishing character is that it is greatly increased by pressure, so that in a severe case the patient cannot support so much as the weight of the bed-clothes, but lies on his back with his knees drawn up, and breathes quickly and lightly, moving the diaphragm as little as possible, so as to avoid the pain which its pressure would excite in the inflamed parts. The bowels in cases of peritonitis are usually, but by no means constantly, constipated; commonly also there are present nausea, vomiting, and hiccup, and almost always excessive thirst and prostration of strength. If not checked in its course, acute peritonitis usually terminates fatally in from five to ten days; the patient becoming more and more depressed, and all the symptoms regularly increasing till within a short time of death, when the pain commonly ceases, and a deceptive improvement in many of the other signs of the disease takes place.

The usual morbid effects of peritonitis are the effusion of serum with lymph or pus into the cavity of the abdomen, and adhesions of the opposite surfaces of the several organs within it. After death from acute peritonitis, the walls of the abdomen and the surfaces of the organs chiefly or alone affected, are found thickened, swollen, and vascular, covered with blotches of dilated blood-vessels, and more or less firmly adhering together by the lymph which is effused between them, and which, if the patient survives for a certain length of time, becomes vascular, and is converted into the usual tissue of adhesions or false membranes. [Inflammation.]

The causes of peritonitis are various. Like other acute inflammations, it may occur after exposure to cold, or the other common excitants of disease; but it is more certainly produced by injuries of the peritoneum, as by tumours developed within the abdomen, by the obstructions which occur in strangulated hernia, and intussusception, of which it is a constant consequence, by the spreading of disease from the adjacent viscera, by heavy blows and falls on the abdomen, by penetrating wounds inflicted in operations for hernia or in other circumstances, by the passage of foreign bodies into the cavity of the abdomen, and especially by the ulcerative perforation or accidental rupture of any of the organs contained within it, and the escape of their contents, circumstances which are productive of the most certainly and rapidly fatal form of the disease.

From these causes acute peritonitis may occur at all periods of life, but it more frequently affects persons of the middle age than any others. Women in child-bed are peculiarly liable to it. They may be attacked either with common peritonitis, presenting no remarkably peculiar symptoms or effects; or they may have that which is especially called puerperal peritonitis. In cases of the latter disease, however, the peritonitis is not always the most important symptom, but must rather be regarded merely as one of the coincidents of the peculiar fever by which the patient is affected, and which often assumes the character of an epidemic.

The treatment of peritonitis may commence with local bleeding by the application of leeches to the abdomen. General bleeding may be had recourse to where the symptoms are severe and the patient's strength will bear it. Hot fomentations should be assiduously applied to the abdomen. Of internal medicines the most effectual is calomel, of which three or four doses of five grains or more, with one or two grains of opium, should be given at intervals of about four hours, and afterwards smaller doses till a slight salivation is produced. During all the time of the treatment, the lowest diet only should be allowed, unless the patient is evidently sinking. In that case, and generally in the later stages of the disease, a more nutritious diet may be given, but there is perhaps no affection in which relapses are so liable to occur in consequence of the early or injudicious use of stimulating food.

Acute peritonitis sometimes, after fifteen or twenty days' continuance, assumes a chronic form. Sometimes peritonitis from its commencement is of slow progress; the pain being but slight or discoverable only by considerable pressure, and the swelling or tension of the abdomen occurring only at a late period of the disease. Its more important symptoms are the low fever, the constant thirst, the hectic flushings of the face, the emaciation, languor, and regularly increasing debility by which it is accompanied. It rarely proves fatal till after many months have elapsed; and its effects are found after death to be thickening and increased density of all the peritoneal coverings, increased vascularity or blackness of their surfaces, which in many cases are beset with vast numbers of minute grayish-white tubercles, and effusions of serum with lymph or pus wherever the adjacent organs are not connected together by the adhesions. The chronic form of disease is always the result of a scrofulous state of the body and is seldom cured. The treatment of chronic peritonitis is usually unsatisfactory and of doubtful benefit. Local bleedings should be employed, and blisters or other counter-irritants should be applied over the abdomen. The diet should be light and nutritious, and, as often as they seem necessary, mild purgatives may be administered. Frictions of ointments containing mercury or iodine are also useful, and iodine should be administered internally when the patient is of a scrofulous constitution.

PERJURY, by the common law of England, is the offence of falsely swearing to facts in a judicial proceeding. To constitute this offence the party must have been lawfully sworn to speak the truth by some court, judge, or officer, having authority to administer an oath; and, under the oath so administered, he must wilfully assert a falsehood in a judicial proceeding respecting some fact material to the subject of inquiry in that proceeding. In a legal sense therefore the term has a much narrower import than it has in its popular acceptation. It is said by Sir Edward Coke (3 'Inst.,' 166) that "the deposition must be direct and absolute, and not *ut putat*, nor *sicut meminit*, nor *ut credit*," &c.; but this doctrine has been long since exploded; and it is now clear that a person may commit perjury by swearing that he *believes* a fact to be true which he *knows* to be false. It is immaterial, with reference to the offence of perjury, whether the false statement has received credit or not, or whether any injury has been sustained by an individual in consequence of it. The characteristic of this offence therefore, by the law of England, is not the violation of the religious sanction of an oath, nor the wrong done to the person or property of another, but the injury done to the administration of justice by false testimony or information in a judicial proceeding.

The history of perjury at common law is entirely dependent upon the history of the trial by jury. Where it is mentioned by Bracton and Fleta, these ancient authors allude exclusively to the offence of jurors in giving a wilfully false verdict; and as the jury appear to have been originally merely witnesses, speaking from their personal knowledge of the facts, and sworn to *speak the truth*, their misconduct in giving a false decision might be justly treated as perjury. As population and civilisation increased, the nature of the trial by jury became changed, and witnesses were called in order to inform the jurors respecting facts of which the latter were commonly ignorant, though the institution was originally founded upon the presumption that they must necessarily be acquainted with them. It is probable that this alteration did not take place at once, but that it was one of those gradual introductions by means of which laws silently adapt themselves to changes in national habits and circumstances. At all events, there is no trace in the statutes or in the reported proceedings of the courts, of any penal law against perjury in witnesses, as distinguished from that of jurors, earlier than the reign of Henry VIII. The date of the introduction of the witness's oath to speak the truth, in use at the present day, is unknown, and no form of process for securing the attendance of witnesses (except where they were added to the jury) seems to have existed before the reign of Elizabeth. These facts tend to show that the offence of perjury has been gradually moulded into its present definite character, by the corresponding change in the functions of the jury. This change however was complete in the time of Sir Edward Coke, as he defines perjury nearly in the same terms in which it is described in the modern text-books. (3 'Inst.,' 163.)

A defendant in equity is guilty of perjury by false swearing in his answer to a plaintiff's bill. He is in fact also a witness, for he is bound to answer on oath to the matter contained in the bill, and the plaintiff may read the whole or any integral portion of the answer as evidence against him. In the case of an answer in equity, the offence of false swearing falls exactly within the definition given above.

The punishments of perjury by the common law were, fine and imprisonment, and the pillory, which latter punishment was abolished in 1837. To these was added an incident probably derived from the punishment of jurors in ancient times, namely, a perpetual incapacity to give evidence in courts of justice. A statute of Geo. II. allowed imprisonment with hard labour for seven years, or transportation for a like period, to be imposed as the punishment for this offence; the effect of recent enactments has been that perjury is now punishable by imprisonment, with or without hard labour, or penal servitude for that term.

Subornation of perjury consists in wilfully procuring any person to commit perjury; and it is essential to this offence that the false oath should be actually taken. The same punishment is assigned to subornation as to perjury.

Besides perjury and subornation of perjury at common law, the statute 5 Eliz., c. 9, contains a legislative enactment respecting these offences; but as this enactment is more limited than the common law, both in the definition of the crime itself and in the punishment to be applied to it, it has seldom been founded upon in recent times; and within the last century there have been few if any instances of prosecutions under this statute. There are also many statutes by which oaths are required as a sanction to statements of facts under a variety of circumstances, and otherwise than in judicial proceedings; and these statutes frequently declare that false swearing in such cases shall amount to perjury, and be punishable as such.

In those cases in which a solemn declaration may be taken in lieu of an oath [Oath], the offence of making the declaration falsely is the same as perjury, and punishable in like manner.

PERMANGANIC ACID. [Manganese.]

PERMUTATIONS. [Combinations.]

PERNAMBUCO-WOOD, COLOURING MATTER OF. [Brazil-Wood, Colouring Matter of.]

PERPENDICULAR (overhanging), the name given in geometry to a line or plane which meets another line or plane without inclining to one side or the other, so as to appear to proceed directly towards the other line or plane. The subject will be considered in a mathematical point of view under Right Angle.

PERPETUAL MOTION. [Motion.]

PERPETUATION OF TESTIMONY. A party who has an interest in property, but not such an interest as enables him immediately to prosecute his claim, or a party who is in possession of property and fears that his right may at some future time be disputed, is entitled to examine witnesses in order to preserve that testimony, which may be lost by the death of such witnesses before he can prosecute his claim, or before he is called on to defend his right. This is effected by such party filing a bill in equity against such persons as are interested in disputing his claim, in which bill he prays that the testimony of his witnesses may be perpetuated. This is the only relief that the bill prays. If the prayer of the bill is granted, the evidence of the witnesses will be taken in the usual way. The depositions, when taken, are sealed up and retained in the custody of the court. When they are required to be used as evidence, they can be so used, by permission of the court, by the party who has filed his bill or those who claim under him, and they can be read by the direction of the court as evidence on a trial at law, if it is then proved that the witnesses are dead, or from any sufficient cause cannot attend. If the witnesses are living when the trial takes place, and can attend, they must be produced. A defendant to such a bill may cross-examine the witnesses and he is entitled to use their depositions as evidence in his favour at a future trial. (1 'Mer.,' 434.)

A bill to perpetuate testimony may be filed by any person who has a vested interest, however small, in that thing to which he lays claim. The parties, defendants to such bill, are those who have adverse interest to the plaintiff. In order that the testimony which the plaintiff seeks to perpetuate may be good evidence for him at the trial, he must make all proper parties defendants to his bill, who may be generally described to be such persons as would be necessary parties to a bill in equity by the plaintiff to enforce or maintain his rights, if a court of equity could take cognisance of the matter, and the question between the plaintiff and such parties could then be raised. The evidence so taken may be read at the hearing of a cause, or at a trial at common law against all such parties to the bill, and those who claim through or under them. The act 5 & 6 Vict., c. 69, entitled "an act for perpetuating testimony in certain cases" makes no change in the procedure of the courts in suits of this kind.

A bill to perpetuate testimony must not be confounded with the practice of examining witnesses De bene esse. The bill to perpetuate testimony has been already described. The examination of witnesses De bene esse is only resorted to when an action has been brought, and the plaintiff is afraid that his witnesses, owing to age or infirmity, may die before the trial can take place, or he has only one witness to an important fact. Both these are in a sense proceedings to preserve or perpetuate testimony; but the one is applicable before the matter which may be in dispute can be the subject of judicial investigation, and the other when an action has been already brought. But under the reformed practice of the courts of chancery and common law a bill to examine witnesses De bene esse appears to be no longer necessary.

Witnesses may be examined De bene esse in a suit in equity, when it is necessary to secure their evidence at a period of the suit prior to the regular time for examination of witnesses in the cause. But this is only a provisional examination, and the evidence can only be used in case the witnesses cannot be examined at the proper time for the examination of witnesses in the cause. The value of the practice is much diminished in consequence of changes in modern practice, by the operation of which the length of time between the institution of a suit and its coming to the issue is greatly abridged. (Daniel's 'Ch. Pract.,' 3rd ed., p. 736.)

PERPETUITY, the technical term for a yearly payment or annuity which is to continue for ever; also called a perpetual annuity.

PERPETUITY (Law). [Settlement.]

PERSEPHONE (Περσεφόνη), or **PERSEPHONEIA** (Περσεφόνεια), called by the Romans PROSERPINA, was the daughter of Zeus and Demeter. (Hesiod. 'Theog.' 913.) She was carried off by Pluto while gathering flowers in the Nysian plain (Homer, 'Hymn in Demet.,' 17), and made the queen of the regions of the dead. Demeter, inconsolable for the loss of her daughter, afflicted the world with sterility; till at length Zeus consented to the return of Persephone to her mother; but as she had eaten food in the regions below, she was obliged to spend one third of the year with Pluto, and was allowed to pass the other two-thirds with Demeter. The tale of the rape of Persephone is related at length in the Homeric Hymn to Demeter, and by Ovid and Claudian. The last two writers state that Proserpina was gathering flowers near the city of Enna in Sicily, when she was carried off by Pluto. In Homer, Persephone is mentioned as the goddess of Hades ('Od.,' xi. 217); but her rape by Pluto is not mentioned either in the 'Iliad' or 'Odyssey.'

Persephone is frequently called Kora (Κόρη), that is, the 'Maiden,' by the Attic writers. This goddess and her mother Demeter were also worshipped under the name of the 'Great Goddesses' (αἱ μεγάλαι θεαί, Pausan., viii. 31, § 1.) [Demeter.]

Representations of Persephone are very numerous in Greek art. The most common in pure Greek sculpture are in connection with her mother; several are mentioned under Demeter. Later she is perhaps most commonly represented as being carried off by Pluto: this was a very favourite type on Græco-Roman sarcophagi, referring to the grief caused by the untimely or unexpected carrying away of a beloved one by Death. Sometimes Persephone is seen enthroned beside Pluto. She appears as a younger Demeter, but is of a graver and more severe countenance: the Hera of the lower regions.

PERSEPOLITAN ARCHITECTURE. [Persian Architecture.]

PERSEUS (constellation). The mythological story of Perseus is well known: in the heavens the constellation is surrounded by Andromeda, Aries, Taurus, Auriga, Camelopardalus, and Cassiopeia. Of the two principal stars α and β (the latter of which is called Algol), the former is situated in the breast of the figure, the latter in the head of Medusa, which he carries in his left hand. The following are the principal stars:—

PERSIAN ARCHITECTURE. Looking at the scanty and imperfect remains of the architecture of ancient Persia, architects and archæologists were unable to trace in them the evidence of a wholly independent style, yet found many difficulties in reconciling their characteristics with those of the buildings of ancient Egypt, the only known architecture to which that of Persia bore any marked resemblance. The remarkable discoveries of MM. Botta and Layard have, however, shown pretty decisively what had indeed been suspected before (Müller, 'Handb. der Archäologie,' § 242), that Persian architecture was really an imitation or development of that of Assyria. [NINEVEH, ARCHITECTURE OF.] The sculptured slabs of ancient Nineveh, the human-headed bulls, the bull-headed capitals, and even many particularities in the arrangement, are seen to have been reproduced at Persepolis and Susa. Persepolis the capital, and Pasargadæ the dwelling place and the grave of the kings of ancient Persia, were contemporary with the later days of Babylon the mighty, and in all of them the same peculiar cuneiform inscriptions are found. [CUNEIFORM.]

For the origin of Persian architecture we need not therefore look farther. The remains of the two kinds are, however, very different. The exhumed buildings of Assyria are essentially palaces. What have been examined of ancient Persia seem to consist chiefly of temples, or temple-palaces, and tombs.

The most extensive and remarkable ruins occur on the site or in the vicinity of Persepolis, the ancient capital. They consist of a series of separate grand halls, probably intended for public receptions and religious ceremonies, in which the monarch took part. One of these halls has been called the palace of Darius, another that of Xerxes, and there are traces of several others; but including all of these the plan would have been exceedingly limited, and inadequate to the accommodation required for the court of an eastern prince and a numerous retinue, unless the buildings originally extended much beyond the actual ruins. Probably, as has been suggested, the actual residences of the family, court, and dependents of the king, were detached buildings, which, being "composed of inferior materials, have been washed away, or they dwelt in the neighbouring palace in the town of Istakr, or in some of the buildings on the plain which are now in ruins." (Fergusson).

The present inhabitants call the chief ruin in Persepolis Tak-Jamschid, or the residence of Jamschid (supposed by them to have been its founder); recent authorities regard it as the hall or palace of Xerxes. By the Mohammedans it is called Tchil-Minar, or the Forty Columns, of which number, however, scarcely half are now remaining. The ruins stand upon an artificial eminence formed of admirably built marble masonry. This height consists of three terraces, and extends upwards of 400 yards from north to south, and about 300 from east to west. Though it may be described as a parallelogram in its general shape, this platform is not perfectly regular in plan, being indented by projections and recesses, which follow the sinuosities of the superficies of the rock itself; neither is it one uniform level throughout, those parts which were covered with buildings being somewhat elevated above the rest. The height above the plain from which the rock rises varies considerably in different places, in some being not more than 14 feet, and in others 40. On every side except the east, where it adjoins a hill forming a lofty screen or background to it, the platform is enclosed by walls or parapets constructed of large blocks of masonry. As that opposite the loftier ground to the east, the west side (1425 feet in extent), may be considered the principal one or front, and accordingly here we find the entrance, not, however, in the centre, but about midway between that and the north-west angle. The ground is here somewhat more than 20 feet below the terrace, owing to which there is a considerable ascent. This gave the architect an opportunity of which he availed himself, to make the entrance by a grand staircase which formed a principal feature in the composition. Instead of being formed by wide flights of steps in a direct line leading to the entrance, it consists of two separate ramps or flights in contrary directions, which return again to the upper landing-place. The lower staircases are of large unadorned courses of masonry: the upper flights are profusely ornamented with sculptured relievi. Facing the upper landing-place, but at some little distance from it, is a *propylon*, or lofty mass forming a doorway, somewhat similar to those in Egyptian architecture, and a little beyond it a second entrance of the same kind, which, as Mr. Fergusson believes, was the opposite entrance to the same pile, which was in fact a distyle hall, having its roof supported by four pillars,—probably one of those Gates of Justice common throughout the east, and of which mention is frequent in the Old Testament. Like the Egyptian, these propyla diminish upwards, and are crowned by a cavetto, or hollow cornice: they are also adorned with fanciful colossal figures of animals, partly in low and partly in high relief, sculptured on their sides,—a human-headed winged bull being sculptured on each of the jambs of the first entrance almost identical in character with those found in the palaces at Nineveh and Khorsabad; whilst at the opposite entrance are bulls without wings. Other but smaller halls are on either side. On the right of this is the grand hall, the approach to which is by another double flight of stairs, the sides of which are lined by treble rows of bassi-relievi slabs, with figures of processions, &c., like those found at Nineveh. The principal mass of building now remaining lies on the south or right hand of the entrance just described, and extends westward. This structure contains within, not a spacious hall suited for entertainments, but one filled with lines of columns, six in each line, so as to form a number of aisles intersecting each other. Such a grove-like arrangement of numerous pillars is altogether unlike anything in Grecian architecture, but a similar disposition of pillars prevailed among the Egyptians, as may be seen in the plan of the temple at Edfu [EGYPTIAN ARCHITECTURE], where both the pronaos and vestibule are in the same manner *polystylar*, or filled with columns, although they occupy a smaller space, and are consequently not so numerous. A more remarkable example is the temple of Karnak, described in the same article. In front, and flanking each side of the great hall, are hexastyle porticoes, the columns being two deep.

There are on the platform several halls or buildings, some appearing to have had four, others sixteen, thirty-two, and one a hundred pillars. This last was a decastyle hall of, as would seem, about 225 feet each way, but as its entire height (according to Mr. Fergusson) was barely 25 feet, it was of low proportions. It had a portico in front flanked by two colossal bulls, on pedestals 18 feet long and 5 feet high; and the flanks of the doorway were sculptured with representations of the king on his throne, and of various mythological subjects; but it had no lateral porticoes, and was altogether inferior in magnificence to the hall of Xerxes.

From a careful comparison of the remains at Persepolis and Susa with those of Assyria and the representations of a Persian palace on the tomb of Darius at Naksh-i-Rustam, Mr. Fergusson conjectures ('Palaces of Nineveh and Persepolis Restored') that two orders of pillars were employed to support the roofs of the palace of Xerxes, one with double bull capitals, the other with the Ionic volutes such as are seen in the columns of the northern portico and generally in interiors. Brackets of wood he thinks supported the beams of the roof, at least internally, the double bull capital surmounting the Ionic scrolls on the outside. The palace, he thinks, "supported a raised platform or *talar*, on its roof; identical with that represented in the tomb (of Darius at Naksh-i-Rustam) on which the fire-altar was placed at which the king used to worship, or on which he was wont to exhibit himself to his subjects on state occasions." On the whole, Mr. Fergusson states as the result of his studies of Assyrian and Persian architecture in general, and of this building in particular, that "presuming it be sculptured and painted as richly as other buildings of its age and class, which it no doubt was, it was not only one of the largest, but one of the most splendid buildings of antiquity. In plan it was a rectangle of about 300 feet by 350, and consequently covering 105,000 square feet; it was thus larger than the hypostyle hall at Karnac, or any of the largest temples of Greece or Rome. It is larger, too, than any mediæval cathedral except that of Milan; and although it has neither the stone roof of a cathedral, nor the massiveness of an Egyptian building, still its size and proportions, combined with lightness, and the beauty of its decorations, must have made it one of the most beautiful buildings ever erected, and both in design and proportion far surpassing those of Assyria, though possessing much of detail or ornament so similar as to be almost identical in style." ('Handbook of Arch.' i. 197.) Of the splendour of the building there can be no question, but of its surpassing beauty we must take leave to doubt.

The taller columns at Persepolis are of gray marble, 5 feet 9 inches in diameter, and 65 feet 8 inches in height; while the shorter; or those with the Ionic scroll, are 40 feet to the bottom of the capital, that, including the Ionic scroll, being 16½ feet: they are therefore of very slender proportions. Of some of these columns the shafts are ornamented with a kind of zigzag or vandyke pattern, after the manner of the fragment found near the Treasury of Atreus at Mycenæ; while others are fluted, but the channels are exceedingly narrow, being forty, or double the number of those of a Doric column. The bases and capitals are still more singular, both of them being very deep and of fanciful shape and outline. The most remarkable are formed by placing two bulls' heads and fore-parts back to back. Those with Ionic volutes have the volutes set vertically instead of horizontally. Mr. Fergusson has given restored copies of the bull-headed columns, and those with Ionic volutes, from Persepolis and Susa in his building called the Assyrian Court at the Crystal Palace, Sydenham.

At Pasargadæ there are vast artificial platforms, and extensive ruins; but none sufficiently uninjured to permit of their identification with any particular edifice, or even to determine to what kind of building they belong. The great platform about 300 feet square, and nearly 40 feet high, is formed of 14 courses of large blocks of white marble, each stone being beautifully fitted and clamped to its neighbour, and bevilled at the joints,—it is therefore admirable as an example of ancient Persian masonry, but of little architectural value. Other marble platforms occur on which also buildings have once doubtless stood, but of which no vestiges remain. In the plain are a fragment or two of large isolated pillars; and a curious tower-like structure of white marble 9 feet square, and 49 feet high. This is probably one of the fire-temples of the ancient Persians. A similar building is found at Istakr, opposite the tombs of Naksh-i-Rustam. It is of marble; and the lower part being solid, it is entered by a door some height from the ground. There is a small square upper chamber, the roof of which is formed by large slabs of stone; and this roof is said to still show marks of fire.

At Susa, Mr. Loftus discovered, in 1843, the foundations of a temple-palace almost identical in plan with the Great Hall of Xerxes at Persepolis, and which though more ruinous than that building, has served to complete our knowledge of the portions there wanting. Many fragments of bases and capitals, like those of Persepolis, but rather richer in detail, were also found among the ruins of Susa. Inscriptions on the bases of the columns record the names of Darius and Xerxes as the builders, and Artaxerxes Memnon as the restorer of the edifice. Other names also occur. This may have been, as has been suggested, the very hall of Shushan, described in the book of Esther; and at any rate the account there given (c. i. v. 6) of the splendour of the fittings, the columns of marble, and the coloured marble pavement, on which were beds or thrones of gold and silver, will serve to indicate the magnificence of the hall when in its pristine glory.

At Naksh-i-Rustam are several tombs and sepulchral chambers hewn out of the perpendicular face of rocks. For the most part these excavations are very shallow, and consist chiefly of an architectural frontispiece or portico richly adorned with sculpture and other decorations. The most remarkable is the Tomb of Darius, the son of Hystaspes, at the foot of Mount Rachmed, near the river Bendemir, the ancient Araxes. This monument has a portico of four columns, whose capitals have figures of the foreparts of animals projecting from their sides. There are also two rows of sculpture above the portico, with a figure of the king above standing opposite a fire-altar, and over all a winged deity is seen floating in the air. As already mentioned, the whole frontispiece of this tomb appears to be intended to represent the royal palace: an excellent engraving of it is given in Coste and Flandin's 'Perse Ancienne.' The only example of a constructed tomb occurs at Pasargadæ, where a small temple stands on the summit of a low pyramid of stone steps, around which, but at some little distance, is traceable a peristyle or colonnade: this is ascertained from the descriptions in Greek writers to be the Tomb of Cyrus.

(Sir R. K. Porter, *Travels*, vol. i.; Chardin, Morin, &c., *Travels*; Hirt, *Baukunst*; Flandin and Coste, *Perse Ancienne*; Fergusson, *Palaces of Nineveh and Persepolis Restored*; *Handbook of Architecture*.)

PERSICA. [Peach.]

PERSONAL ACTIONS. [Actions.]

PERSONALTY AND PERSONAL PROPERTY. [Chattels.]

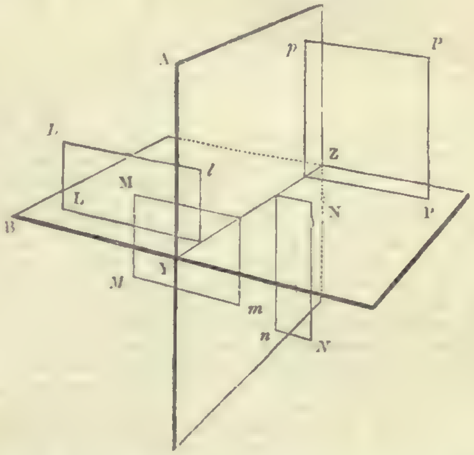
PERSPECTIVE, a term popularly given to an application of geometrical principles, by means of which a *pictorial* outline of a certain class of objects may be delineated on a plane surface. Thus understood it has been defined to be the art of representing on a plane surface the outlines of objects in the same forms, positions, and relative proportions which they bear to each other in nature as seen from a given point. A perspective representation corresponds in fact to a section of a cone of rays, the apex of which is in the eye of the observer (62, 64). In other words, if a pane of glass were interposed between us and any object or objects which we were viewing through a small hole (or *sight*), and we were to trace on the glass an accurate outline of the objects as they appeared on it, that outline would be a perspective representation: and it is the purpose of the art of perspective to show how this may be done if the necessary data be furnished. Perspective constitutes however only a specific case of a more general application of the geometrical principles above alluded to, which enable us to make constructions relating to geometrical *solids*, bearing the same relation to geometry of three dimensions that practical bears to theoretical plane geometry. In the present article these principles will be explained, and their application to perspective be shown (66 *et seq*),—specifically with reference to geometrical solids, but capable of extension to the objects delineated in pictorial representations.

The analyst, in his investigations of symbolical expressions for the relations of geometrical magnitudes, refers these, according to the species of magnitudes under consideration, either to co-ordinate lines on a plane, or to co-ordinate planes, assumed at pleasure in space. [Co-ordinates.] The draughtsman, or practical geometrician, makes his constructions on the lines and figures themselves, when they lie wholly in one plane; and when he has to make constructions on geometrical solids, he is compelled to refer the various points, lines, and figures connected with or constituting those solids to one or more planes, to effect his object; and from constructions on these planes he can determine the unknown quantities of the original solids by means of their *projections*, as they are termed, knowing the conditions under which these projections were obtained.

1. The series of points of any geometrical solid are most simply supposed to be referred to a plane by parallel right lines, passing through them perpendicular to the plane; the intersections of these lines with the plane are termed the *projections* of the original points on that plane.

2. Let us conventionally designate the original points by Italic capital letters, and their projections by small letters; thus *P* means a point in space, *p* its projection on a plane.

3. The points *l*, *m*, *n*, on a plane AYZ, are therefore understood as referring to the points in space, situated in right lines passing through *l*, *m*, *n* respectively, perpendicular to that plane; but these projections alone do not define the relations between the original points; for *l*, *m*, *n* are each the projections of an infinite number of original points, of all in short through which each *projecting line* may pass. To define the specific points *L*, *M*, *N*, we must consequently not only have *l*, *m*, *n*, but the lengths respectively of the projecting lines *Ll*, *Mm*, *Nn*, or the distances at which *L*, *M*, *N* are respectively situated from their projections.



4. This second series of essential data is furnished by the projections L, M, N of the original points on a second co-ordinate plane BYZ, perpendicular to the first, and therefore parallel to the former projecting lines, by which *l*, *m*, *n* were determined; while, conversely, the first plane must be parallel to the projecting lines by which L, M, N are determined. For if a third plane be conceived to pass through the two projecting lines *L*L, *Ll*, of any point *L*, and therefore necessarily perpendicular to the two co-ordinate planes, the intersections of this third plane with the two latter will, together with the two projecting lines themselves, form a rectangle; consequently the distance of any projection L, from the common intersection YZ of the co-ordinate planes, is equal to the length of the *projecting line Ll*, which is parallel to it; while, conversely, the distance of the other projection *l* of the same point *L* from the same common intersection is equal to the length of the *projecting line* L *L*.

5. Let us designate the third plane just described as the *projecting plane* of an original point. It follows as a corollary from this definition of the plane, that the *projecting planes* of a series of points L, M, N are parallel to each other, and perpendicular to both co-ordinate planes, as well therefore as to the common intersection YZ of those co-ordinate planes.

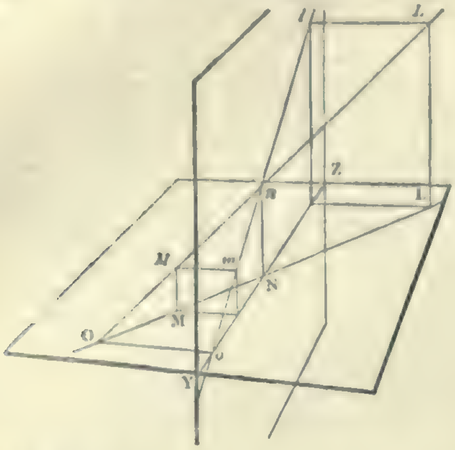
6. Let YZ always designate the common intersection of the two co-ordinate planes; let the projections L, M, N be termed the *plans*, and the projections *l*, *m*, *n* the *elevations* of the original points *L*, *M*, *N*. It follows that if an original point lie in either co-ordinate plane, its projecting line will coincide with that plane, and its projection on the other will be a point in YZ.

7. Let us next consider a right line *LM*, supposed to join or pass through two points in space *L*, *M*. Then the right line LM joining or passing through the *plans* of *L* and *M*, is called the *plan* of *LM*, and *lm* is the *elevation* of the same original line.

8. It is obvious, from the preceding definitions, that the *plan* and *elevation* of any original right line *LM* in space are the intersections with the co-ordinate planes respectively of two planes passing through the original line perpendicular to the co-ordinate planes.

9. We will distinguish the projecting plane of an original line *LM*, by which the *plan* of that line may be conceived as produced, as the *plan-projecting plane* of *LM*; and the projecting plane by which *lm* is produced, as the *elevation-projecting plane*. But the reader must not confound the *projecting plane* of an original point, which is necessarily perpendicular to both co-ordinate planes, with the *projecting plane* of an original line; which, though necessarily perpendicular to one co-ordinate plane, may be parallel, perpendicular, or oblique to the other, according as the original line is parallel, perpendicular, or oblique to that other co-ordinate plane. Nevertheless the projecting plane of an original line will always intersect that co-ordinate plane, to

which it is not necessarily perpendicular, in a line which is perpendicular to Y Z.



10. Besides the plan and elevation, there are two other elements regarding an original line which it is necessary to consider; these are the points in which that line itself intersects the two co-ordinate planes. The principles of projection furnish us with the following theorems relating to these points, and to the plan and elevation of the line.

11. If the original line be parallel to both co-ordinate planes, it can intersect neither, and both its plan and elevation are parallel to Y Z. It is clear, on this supposition, that the original line is itself also parallel to Y Z.

12. If the original line be perpendicular to one, and therefore parallel to the other co-ordinate plane, the projection on that other plane will be parallel to the original, and perpendicular to Y Z, while the projection on the first will be a point, that in which the original line itself intersects that co-ordinate plane.

13. If the original line be oblique to one, and yet parallel to the other co-ordinate plane, its projection on that to which the line is *not* parallel will be parallel to Y Z; while its projection on the co-ordinate plane, to which the original is parallel, will cut X Z in the projection of the point in which the original intersects the former co-ordinate plane.

14. If the original line be oblique to both co-ordinate planes, neither its plan nor elevation can be parallel to Y Z; the plan of the line will cut Y Z in the projection of the point of intersection of the original with the co-ordinate plane in which its elevation lies; while that elevation will cut Y Z in the projection of the intersection of the original with the plane in which the plan lies.

15. It also follows that the projecting line of the point in which an original line intersects either co-ordinate plane coincides with the intersection of the projecting plane of that line.

16. If an original line, oblique to both co-ordinate planes, lie in a plane perpendicular to them both, its plan and elevation will both be perpendicular to Y Z, since its two projecting planes will coincide with that in which the line lies. In this case the plan and elevation could not furnish sufficient data for determining the original lines, since they would be common to every line, in the perpendicular plane, which was not parallel to either plane of projection; if however we have, in addition to the indefinite plan and elevation of the line, those of two points in it, or the two points in which the original line cuts the two co-ordinate planes, then the original line is determined.

17. Let us next consider in what manner an original plane may be conceived to be referred to two co-ordinate planes. It is clear that as only one plane can be drawn through a straight line and a point, or, which is the same thing, through the two legs of a plane angle, the plans and elevations of any two lines through which the plane passes will determine it. But the intersections of the original plane with the two co-ordinate planes furnish a datum regarding it of more direct application.

18. The intersections of an original plane with the co-ordinate planes are termed its *traces*.

19. The traces of a plane on either co-ordinate plane will obviously pass through the points in which two or more lines lying in the original plane intersect that co-ordinate plane.

20. If an original plane be parallel to one co-ordinate plane, its trace on the other will be parallel to Y Z.

21. If an original plane be perpendicular to either co-ordinate plane, its trace on the other will be perpendicular to Y Z, at the point in which the trace on the first plane meets that line; and the plane oblique angle formed by the trace and Y Z will be the measure of the dihedral angle formed by the original with the other co-ordinate planes. If an original plane be perpendicular to a co-ordinate plane, its trace on that plane will be the common projection of all lines in the original plane, and will pass through the projection of all points in that original plane.

22. If the original plane be parallel to Y Z, its traces on the co-ordinate planes will both be parallel to Y Z, and therefore to each other; but in every other case, if the original be oblique to both, or meet both co-ordinate planes, its traces on them must intersect in a point of Y Z. And if the plane be perpendicular to both co-ordinate planes, both its traces will be perpendicular to Y Z.

23. If two original lines are parallel, the plans of those lines will be parallel, as will also be their elevations; but the plans or the elevations only of two lines may be parallel, although the lines themselves are not so, the parallelism of either the plans or elevations simply arising from the accidental parallelism of the plan or elevation projecting planes of the original lines.

24. An analogous theorem applies to two original planes: if these be parallel, their traces on both co-ordinate planes will be parallel; but if their traces are parallel on one plane only, it simply indicates that the original planes intersect each other in a line parallel to that co-ordinate plane.

25. The planes of two lines may cut one another, as may also the two elevations, and yet the originals may not lie in one plane, and therefore cannot meet each other. If two original lines really intersect, the points in which the plans and elevations cut each other must lie in the projecting plane of the point in which the originals meet.

26. The projections of equal parallel lines will be equal parallels, in the ratio to the originals of the cosine of the angle in which those originals are inclined to the plane of projection, to radius. If two lines forming an angle be parallel to two others, whether lying in the same or different planes, the projections of each two lines will form equal angles.

27. The plane angles, which are the projections of equal angles, will be equal, provided the original angles are similarly placed with respect to the traces of the planes in which those originals lie; or else when the original angles lie in a plane parallel to either co-ordinate plane, and then the projected angles must be equal to the originals.

28. Hence, since the projection of every parallelogram is a parallelogram (23), the angles of the projection corresponding to the adjacent angles of the original figure will also be complementary to each other.

29. If an original plane and line be mutually perpendicular, the projection of the line will be perpendicular to the trace of the plane on each co-ordinate plane. For since the projecting plane of the line must, on this supposition, be perpendicular both to the original and to the co-ordinate plane, and consequently so to their common intersection, which common intersection is the trace of the plane, this projecting plane will cut the co-ordinate plane in a line, namely the projection of the original, perpendicular to the trace of the plane.

30. If a line in an original plane be parallel to a co-ordinate plane, the projection of that line will be parallel to the trace of the plane; and conversely, if the projection of a line situated in a plane be parallel to the trace of that plane, the original line is parallel to the co-ordinate plane in which that trace lies.

31. These theorems on projections would be useless to the practical geometrician so long as the co-ordinate planes are supposed to retain their relative situation in space; to enable him to make the requisite constructions on the projections, and to determine the unknown magnitudes entering into the original solids by means of the projections of the known ones, he supposes the one co-ordinate plane turned round on the common intersection Y Z till the two planes coincide in one and the same plane: by this supposition the relations to Y Z of the lines, points, and traces, on the plane which is supposed to be turned round, remain unaltered; while the principles on which the projections are made allow of the correct interpretation of the new relations which the projections of original points and lines on one plane assume with regard to the projections of the same points and lines on the other plane, when these two co-ordinate planes are supposed to coincide in one.

32. The same method of bringing two planes into one may be applied, or rather conceived to be applied, to the *projecting plane* of any original point or line, this projecting plane being supposed turned round on the projection of the line till the plane coincide with the co-ordinate plane, that is to say, a construction can be made with the projection of a line founded on this supposition, by which a line may be found representing the original line as brought into the co-ordinate plane; and by an analogous construction, an original plane may be constructed as if turned round on its trace till it coincide with the co-ordinate plane.

33. This principle may be carried still farther: thus a construction can be made, founded on the supposition that an original plane has been turned round on its intersection with another such plane till they coincide, and this compounded plane, if we may use such an expression, has been again turned round on its trace till it has been brought into the common plane of projection.

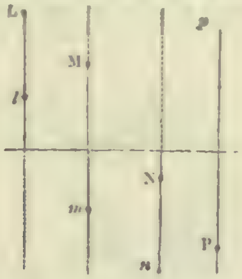
34. It must hence be understood that the practical application of the theory of projections is entirely synthetical, that is, the draughtsman, first drawing a line to represent Y Z, proceeds from this simple assumption to draw the projections of certain points and lines of a solid, on which he proposes to operate, from their known, assumed, or

given relations to each other, and from their conventional relations to the supposed co-ordinate planes, which may in every case be conceived to be so situated as to facilitate these constructions. Having thus got the projections of known or given lines, he proceeds from these data to ascertain the absolute magnitudes of lines and angles depending on these given ones, by making the constructions alluded to, founded on the supposition of projecting lines and planes being turned round on the projections determined by them, till they coincide with the co-ordinate planes.

35. If a plane be turned round on its intersection with another, a line in the former will make the same angle with that intersection, when the two planes are brought into one, that the line made with that intersection when the planes were in situ. The two lines which are the intersections of the projecting plane of a point (5) with the co-ordinate planes in situ, which lines have been shown to be equal respectively to the projecting lines (4) of that point, will be both perpendicular to Y Z, and therefore will coincide in one line perpendicular to that line Y Z, when the two co-ordinate planes coincide in one.

36. The two co-ordinate planes in situ form four dihedral angles, and an original point may be situated in any one of these; that is to say, of a system of related original points referred to those planes, some one or more may be in different dihedral angles: it is essential that the learner should know how to assign the relative situation of the original points in space from the relative situation of their plans and elevations to Y Z.

37. Let us distinguish the four dihedral angles thus:—

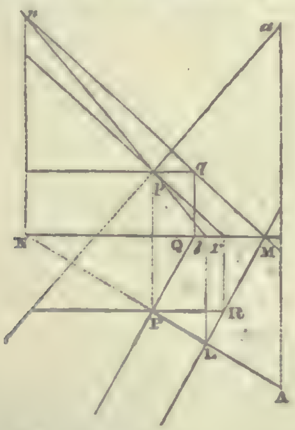


1. $+x+y$; the point P, p[*] is n the dihedral angle No. 1.
2. $-x+y$; „ L, l „ „ No. 2.
3. $-x-y$; „ M, m „ „ No. 3.
4. $+x-y$; „ N, n „ „ No. 4.

38. Our limits will only admit of two or three examples of elementary constructions to illustrate the subject of projections, referring to the theorem on which each step of the construction is founded.

Given a point P p *in a given line* A P, ap, *to draw a plane through* P, p *perpendicular to the given line.*[†]

39. Draw a line P Q through P, perpendicular to the plan of the line, for that of a line parallel to the co-ordinate plane, and lying in the



plane sought; then (20) $p\,q$, parallel to Y Z, will be the elevation of this parallel. The line P Q, $p\,q$ meets the co-ordinate plane in Q, q (13) q therefore will be a point in one trace of the plane sought: and since this trace must be perpendicular to the elevation of the line, M n drawn through q perpendicular to $a\,p$ will be that trace. The same construction, applied, mutatis mutandis, to the other projection of the point, will furnish a point in the horizontal trace of the plane sought, which trace must be drawn through R perpendicular to A P. The two traces thus found will intersect each other in a point of Y Z (22).

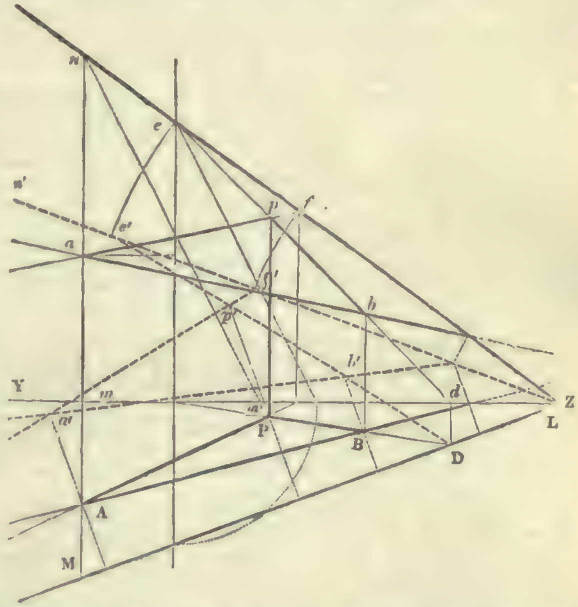
Given a plane L M, M n, *and a point* A, a: *to draw a line through the point perpendicular to the plane, and to determine the point in which this line cuts the given plane.*

40. Through A, a draw lines perpendicular to the given traces LMn for the indefinite projections of the perpendicular sought (29): from the point N, in which A N cuts Y Z, draw N n perpendicular to Y Z for the intersection with the other co-ordinate plane of the plan-projecting plane of the perpendicular (9); and from L, in which A P cuts M L, draw L l perpendicular to Y Z: the point l is the elevation of the point in which the plan-projecting plane of the perpendicular cuts the trace LM, M l; and n is that in which the same plane cuts the trace M n. Consequently $n\,l$ is the elevation of the intersection of the same plan-projecting plane with the original plane. Now it is obvious that the point sought must lie in this intersection; consequently the point p, in which $a\,p$ cuts $n\,l$, must be the elevation of the point in which the perpendicular intersects the given plane.

41. The plan P of the point may be obtained by drawing P p perpendicular to Y Z (35), to cut A N, the indefinite plan of the line; or by applying the foregoing construction, mutatis mutandis, to the other projections.

To draw a line through a given point P, p, *to make any proposed angle with a given line* A B, $a\,b$.

42. If the proposed line is to be *parallel* to the given one, lines drawn through the projections of the given point, parallel respectively to those of the given line, will be the projections of the line sought (23); but if the lines are not to be parallel, join P, p with any two points A, a, B, b, taken at pleasure in the given line. A B P will therefore be the plan, and $a\,b\,p$ the elevation of the triangle thus formed. Find the traces, M L, L n, of the plane of this triangle, by finding the points in which any two of its sides intersect the co-ordinate planes (19), since these points must lie in the traces required.[*]



43. Draw M n perpendicular to Y Z, to cut the traces anywhere at pleasure in points M, n; the line M m, n is consequently the traces of a plane assumed at pleasure as perpendicular to both co-ordinate planes (22), and cutting the given plane M L n in a line, the projections of which, of course, coincide with the traces of the plane. The length of this line, or the real distance between the points M n when in situ, is obtained by making $m\,m'$ in Y Z equal to m M; then the hypothenuse $m'\,n$ is the intersection of the given plane with the assumed plane, brought into the plane of projection by the rotation on $m\,n$ of this assumed plane.

44. From M and L, as centres, with $m'\,n$, L n for radii respectively,

---

[*] 'The point P, p,' 'the line AB, ab,' 'the plane LM, Mn,' signify the point, line, or plane, the plans, elevations, or traces of which are A, a; AB, ab; LM, Mn, respectively.

[†] This is the form of enunciation of a prob. in solid geometry, and is to be thus interpreted: Given the projections P and p, on two co-ordinate planes supposed to be brought into one, of a point *P* situated in an original line of which the corresponding projections, A P, $a\,p$, are given; to draw the lines (traces) which will represent the intersections of a plane with those co-ordinate planes, this plane being supposed to pass through P, and to be perpendicular to *A P*.

[*] The sides of the triangle may meet the co-ordinate planes in different dihedral angles; the projections of two of these points, through which the same trace must pass, may therefore lie on contrary sides of Y Z. The traces of all planes should be drawn indefinitely extended on each side of this line Y Z, or are to be conceived as so extended when circumstances do not admit of their being shown so

describe arcs cutting in n′. Join M n′, L n′; the triangle M L n′ consequently (32) represents that portion of the given plane M L n intercepted between the co-ordinate planes and the line M m, m n, brought into the co-ordinate plane by being turned round on the trace M L, and by this rotation, bringing the original of the triangle, P A B, p a b, along with it. To draw this triangle as thus brought into the co-ordinate planes, produce P B, p b, to cut the two traces in D and e respectively, make L e′ equal to L e, join D e′. In the same manner the lines a′ p′ a′ b′ are obtained, constituting the original triangle as brought into the co-ordinate plane in the manner described.

45. The points A a, B b, P p, lying in the original plane, will describe arcs of circles during the rotation of that plane on its trace: the planes of these circles must obviously be perpendicular to the original plane and to the co-ordinate plane, and consequently cut the co-ordinate plane in lines or traces perpendicular to M L, that of the original plane. Hence if lines be drawn through A, B, and P, perpendicular to M L, they will pass through a′, b′, and p′, since the traces of these planes will be the projections of all lines lying in them, and therefore of the circular arcs alluded to (21), in which the points a′, b′, and p′ lie. By this means the points a′, b′, and p′ may be found, or verified if previously obtained on any other principle.

46. Draw p′ a′ to make the proposed angle with a′ b′*; then the plan A, and elevation of the point a′, in which the proposed line meets the given one in the given angle, may be determined from a′ by the converse proceeding to that by which a′, b′, and p′ were obtained. And lastly, P A, p a will be the projections of the line as required.

47. The foregoing construction might have been made with the trace L n instead of L M; but the triangle, when brought into the co-ordinate plane on the supposition of the rotation of the plane of that triangle on L n, would not coincide with a′ b′ p′.

48. If a line be conceived to move always perpendicular to a co-ordinate plane, and pass through an original curve, its intersection with the plane will be the projection of the curve; this projection being the section of the cylindroidal surface formed by the generating line. If the curve be any other than a circle or an ellipse, its projection can only be practically described by finding the projections of a sufficient number of points of the original, from some known property of the curve, or from the mode of its generation; and the required projection must be drawn by hand through the points thus determined. It is obvious that the projection of any plane curve which is parallel to the co-ordinate plane must be equal and similar to the original. But if the original curve be a circle, or an ellipse, the projecting line during its motion will generate a right or oblique cylindrical surface, the section of which by the co-ordinate plane must be either a circle or an ellipse.

49. Whatever may be the oblique position of an original circle with respect to the co-ordinate plane, there must be one diameter which is parallel to that plane; now the projection of this diameter being equal to the original, must be greater than those of all the other diameters of the original circle, which are all necessarily oblique to the plane: and since the projection of every diameter must be a diameter of the projected curve, the projection of this parallel one must be the major axis of the ellipse. This diameter of the original circle parallel to the co-ordinate plane is that which is parallel to the trace of the plane. The conjugate axis of the ellipse will be the projection of that diameter of the original circle which is perpendicular to the former, or to the trace of the plane.

50. The projection of a sphere on a co-ordinate plane must be a circle of the same radius as the sphere, this circle being the projection of that great circle of the solid which is parallel to the co-ordinate plane.

51. In the applications of practical geometry to the arts, the object is either to delineate the forms to which materials are to be reduced, or to guide workmen in making and putting together machinery; or, in the construction of edifices of every description.

52. Owing to the symmetry of the machines or edifices, the forms most commonly required to be delineated are reducible to series of rectangular geometrical solids, the planes of which are either parallel or perpendicular to the horizon. The plans, elevations, sections, profiles, &c., furnished to the workman by the draughtsman, are the projections on rectangular co-ordinate planes, assumed to be parallel to the planes of the machines or edifices, made to a reduced scale; the plan being such a projection, made on a horizontal plane, and the elevation on a vertical plane. When the building or engine is supposed to be laid open, by being cut by a plane, so as to show its interior, the projection made on this supposition is termed a section, or profile.

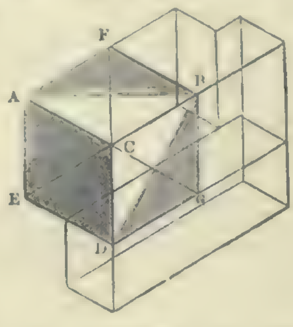
53. It is obvious, from these assumptions, that the various plane rectilinear, or mixed, figures which are produced by the intersections or boundaries of the various surfaces of the original objects, are represented on the draughtsman's plans, &c., by figures similar to the original forms; and that those plane surfaces of the original object which are vertical to the horizon appear only as right lines on a plan, bounding the figures which are the representatives of original planes parallel to the horizon; and, conversely, these last-mentioned surfaces are represented by lines in the elevations, while the vertical plane figures of the original are projected into similar plane figures on these elevations or profiles.

54. Hence two, at least, and commonly three, such projections, on rectangular co-ordinate planes, are requisite to convey an idea of the forms of an original object; but since these forms of the original are represented of their true dimensions and proportions, such projections are sufficient, and indispensable, as guides to the mechanics who are to construct or put together the edifice or machine.

55. The principles of projection enable us, as far as regards the rectangular parallelopiped, the solid of most frequent occurrence, to combine the two purposes for which such projections are employed; that is, to convey, by one image or figure, an accurate idea of the relative position of the parallel and vertical planes of an original object, reducible to this form, and at the same time to preserve one constant and correct proportion between the magnitudes of the original and of its representative.*

56. It has been shown (26, 27) that the projections of definite right lines, inclined in equal angles to the co-ordinate plane, will be in a constant proportion to the originals; if, therefore, the three plane right angles forming a solid angle of a rectangular parallelopiped be inclined in equal dihedral angles to the co-ordinate plane, all lines parallel to the three edges of that solid angle will be projected into lines bearing one constant ratio to the originals, and forming with each other equal angles, which are the projections of the right ones formed by the original lines.

57. Thus, for example, if the co-ordinate plane be assumed perpendicular to the diagonal of a cube, the projections of the three edges meeting in either end of that diagonal will form angles of 120° with each other, and the three projections of the edges at one extremity will, respectively, bisect the equal angles formed by those of the edges at the other extremity; while the lines joining the ends of these six equal radii, which lines must obviously form a regular hexagon, will be the projections of the remaining edges of the solid. Each face of the cube is projected into an equilateral rhombus, as ACBF, BCDG, ACDE, BFCG, &c., the sides of which form angles respectively of 120° and of 60° each. If the side of the cube be unity, the equal projections of those sides will be ·8165, which is equal to the cosine of the angle at which the originals are inclined to the co-ordinate plane. The original diagonals of the three faces, AB, BD, DA, are obviously, from the symmetry and position of the solid, parallel to the co ordinate plane; their projections are therefore equal to those originals, or are each equal to $\sqrt{2}=1{\cdot}4142\ldots$ If an original solid be made up of rectangular parallelopipeds, having their faces mutually parallel, and the co-ordinate, or plane of projection, be assumed as equally inclined to the three faces forming any of the solid angles, the projections of all its edges, and of all lines parallel to them, would be in the constant ratio to the originals of ·8164 : 1; the dimensions, consequently, of those originals, as measured in the directions of lines which would be isometrically projected, may be set off from any scale along the isometric projections of any lines parallel to the edges of the original solids, and a figure or image of the original constructed which would show the three principal series of planes of which that original was composed.



58. The projections of all circles equally inclined to the co-ordinate plane will be similar ellipses; the axes of these ellipses, when representing circles lying in planes parallel to the faces of a cube equally inclined to the co-ordinate plane, will be to each other in the ratio of the diagonals of the rhombus representing the inscribed or circumscribing square isometrically projected. The following simple method of constructing a scale for determining the lengths of the axes of the isometric projection of a circle will be of service to the practical draughtsman. Construct a right-angled triangle the base and perpendicular of which are in the ratio of the side to the diagonal of a square, or as 1 : 1·4142. Set off the length of the isometric projection of the circumscribing square of any original circle along the side of this triangle, from the acute angle, and draw a line parallel to the other

---

* In the figure, p′ a′ is shown as the same line as the side of the assumed triangle, to avoid confusion; but this, obviously, need not be the case.

* This specific application of projection was termed *Isometric* by the late Professor Farish, who pointed out its practical utility, and the facility of its application to the delineation of engines, &c.: as a distinctive one, this term is unexceptionable.

side from the point thus marked off; this parallel, and the segment of the hypothenuse cut off by it, will be the minor and major axes of the ellipse. Since the major axis of the elliptic projection of a circle is always equal to the diameter of that circle (49), the major axis of the isometrical projection of a circle is equal to the side of the circumscribing square. Hence the axes of the ellipse and the side of the circumscribing square, when isometrically projected, are as $\sqrt{3} : \sqrt{1};\ \sqrt{2}$.

59. The projecting lines and planes are assumed perpendicular to the rectangular co-ordinate planes, simply to facilitate the construction; but it is obvious that lines and figures may be projected on a plane by parallel projecting lines, making any angle with the plane of projection; such projections are termed *oblique*, but as they are but seldom employed, we shall only here give two general theorems relating to them; since we shall have occasion to recur to this subject in a subsequent part of this article. The oblique projection of a straight line, figure, or curve, lying wholly in a plane parallel to the co-ordinate plane, will be similar and equal to the original; and the oblique projections of parallel right lines will be parallels.

60. The oblique projection of a sphere must be an ellipse, for the parallel projecting lines which are tangential to the spherical surface must always form a right cylinder, the oblique section of which must be an ellipse. The major axis of this ellipse will be the intersection with the co-ordinate plane of one perpendicular to it, and passing through the oblique projecting line of the centre of the sphere. This major axis will consequently pass through the perpendicular, or ordinary projection of the centre of the sphere. The conjugate axis must clearly be equal to the diameter of the sphere.

61. We now proceed to show how, by a modification of the principles of projection, an image of an object, or a pictorial outline of it, may be obtained. It is however only to buildings, engines, machines, &c., consisting of strictly geometrical forms, that this modified projection can be applied; since the constructions by which these projections are obtained are as strictly geometrical as those by which we obtain the projections of such objects on co-ordinate planes.

62. Each point on the surface of an object is seen in the direction of a straight line,* supposed to be drawn from that point to the eye, and representing the reflected ray of light by which that point is rendered visible. The rays from every point of that surface will obviously form a geometrical solid pyramid, the surface of which will be composed of those rays which, touching the object, might be supposed prolonged in the same straight direction beyond it, without penetrating its surface. But when considering the subject of *outline* alone, we need only regard such of the internal rays of the pyramid as proceed from lines on the surface of the object, produced by the intersections of portions of that surface not continuous: and from our limitation of the class of objects, such lines must be either straight, or else geometrical curves; resulting from the mutual intersection of planes and curved surfaces with each other.

63. The general pyramid of rays will therefore be made up of a series of others, having one common vertex, and for their several bases the perimeter of a portion of continuous surface.

64. If we imagine these pyramids of rays cut by a plane, the common section will obviously be an outline of the object as it would present itself to an eye placed at the vertex, each line and point of the section coinciding with the corresponding line and point of the original.

65. As long as the object and the spectator's eye retain the same relative position, it is immaterial in what direction or at what distance the plane cuts the pyramids of rays; for the lines and points produced at each position of the plane must necessarily coincide with the originals when viewed from the vertex; although the outlines on the plane would vary for each of its positions. But each of these different outlines would suggest to the mind the same original combination of forms, provided it be viewed from the true vertex, and cannot be a correct representation or image of the object, if viewed from any other point.†

66. When we revert to the connection between this subject and drawing, in the common acceptation of the word, we shall point out the precautions that must be taken by the draughtsman, when applying the principles of projection to the pictorial delineation of objects, to prevent his drawing from appearing distorted when viewed indifferently from other than the correct point, which it must inevitably be on most occasions. But at present, dismissing all considerations of light, vision, and art, we shall proceed to treat this branch of the subject of projections, termed perspective, in a purely geometrical manner.

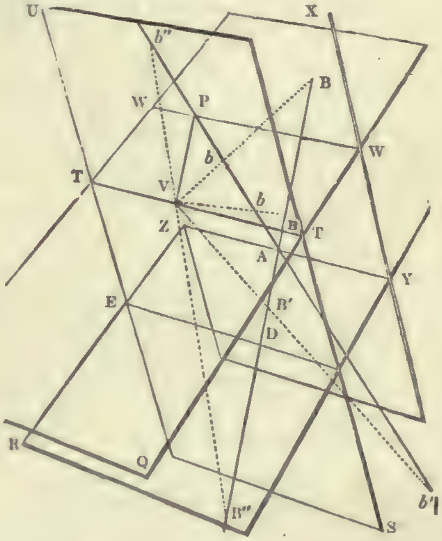
67. Instead of the simple elements alone, which entered into the constructions for determining lines and points, referred to a co-ordinate plane, by parallel lines perpendicular to that plane, we have in perspective projection the additional elements of the convergence of the projecting lines, or rays, intersecting the plane at different angles, depending conjointly on the distance of their point of convergence from the original lines, and from the plane. This variation in the conditions necessitates a different course of proceeding: in the former kind of projection the object of our constructions was to determine magnitudes; in that we are about to consider, our object is to delineate apparent and not real form.

68. The following definitions are here given to avoid unnecessary repetitions. The plane, on which the projection is supposed to be formed, and which is represented by the drawing board or paper on which the constructions are made, will always be termed *the plane of the picture.*

69. The point of convergence of the *rays*, or *projecting lines*, or the vertex of the pyramids of rays, will be designated as *the vertex.*

70. *The centre of the picture* is the point in which a line, through the vertex, perpendicular to the plane of the picture, meets that plane; and the length of this perpendicular, from the vertex to the centre of the picture, is *the distance of the picture or vertex:* this term will also be applied to the line itself when we have occasion to refer to it.

71. The *vertical plane* is one passing through the vertex, parallel to the plane of the picture.



72. Let X Y Z ... and U T E S, in the figure, be the plane of the picture and the vertical plane; V in the latter being the vertex. Let B B″ be any straight line taken as an elementary original object: the rays from every point in B B″ will lie in one plane, the intersection, b′ b″, of which with the plane of the picture will be the indefinite perspective projection or *image* of B B″: the projecting plane (9) passing through any original line B B″ and the vertex will also intersect the vertical plane in a line V D, parallel to b′ b″. V D is *the director* of the original line.

73. If the original line B B″ were parallel to the plane of the picture, and therefore also to the vertical plane, its indefinite image and director would be parallel to the original line. But if B B″ be not parallel to the plane of the picture and vertical plane, it must intersect them both.

74. The point A, in which any original line cuts the plane of the picture, is termed its *intersecting point;* and D, in which it cuts the vertical plane, is termed the *station point* of that original line.

75. If a line V P be supposed to pass through the vertex, parallel to any original line B B″, it will cut the plane of the picture, if the original line itself be not parallel to that plane. This line V P is termed *the radial* of B B″, and the point P, in which this radial cuts the plane of the picture, is *the vanishing point* of the original line.

76. If any original line pass through the vertex, its radial will coincide with it, and the point in which such a line cuts the plane of the picture will not only be its common intersecting and vanishing points, but also the common image of all points in the original line, and consequently of the entire line itself.

77. It follows from these theorems that the original line, its director, its radial, and its image, all lie in its projecting plane, and therefore its image must pass through its intersecting and vanishing points; while its director must pass through its station point: and that these four lines must form a parallelogram, unless the original line be parallel to the plane of the picture; in which case the director and radial will coincide in one line, lying in the vertical plane, parallel both to the original and to its image.

78. Let us now consider the projection or image of any point B in an original line B B″, and the situation of that image in the indefinite one of the line, according to the position of the point B.

---

* We need hardly allude to the modification of this assertion rendered necessary by the effects of atmospheric refraction. It is evident that the *forms* of objects which can be seen by the eye at one time are in no way influenced by these effects, which may therefore be neglected in treating this subject.

† There is a common toy which well illustrates this subject; we allude to a distorted image of a building, which, when viewed from a certain fixed point, presents a natural appearance. This distorted image is a correct section of a pyramid of rays supposed to proceed from the building to the point in question, and therefore when viewed from that true vertex, conveys the same impression that the building itself would do.

If B be at A, the intersecting point of B B″ (74); B and its image b[*] will coincide. If B lie in that part of A B which is on the contrary side of the plane of the picture to that on which the vertex is situated, its image b will lie between the intersecting and vanishing points, A, P, of the line: and if B be supposed to recede farther and farther from the former, the nearer to the latter will its image approach; so that the vanishing point is the *limit* of the successive images of points, farther and farther distant from the vertex, or it may be considered as the image of an infinitely distant point in the original line.

79. If the point B′ be situated between the intersecting and station points of the line, its image b' will be on the contrary side of the intersecting point to that on which the vanishing point P is situated; and if B be the station point D of the original line, it can have no image, or its image may be considered at an infinite distance from the vanishing point in either direction.

80. If the point B″ lie on the contrary side of the vertical plane to that on which the plane of the picture is situated, its image b'' will lie on the contrary side of the vanishing point to that on which the intersecting point is situated; and, as before, the vanishing point may be considered as the limit of the images in this direction; or as the image of a point in the original line at an infinite distance from the station point in either direction.

81. Let two or more original lines be conceived as lying in an original plane Y Z, and suppose a plane W, which will be termed *the vanishing plane* of the original one, to pass through the vertex parallel to that original plane. The lines Y Z, D E, in which an original plane cuts the plane of the picture and the vertical plane, are called the *intersecting and station lines*, respectively, of that plane; and the lines W P, T V T, in which the vanishing plane cuts the same two planes, are called the *vanishing line* and *parallel of the vertex* to that original plane.

82. The intersecting, station, and vanishing lines, and the parallel of the vertex, are all parallel to each other, these four lines being the mutual intersections of two parallel planes by two other parallel planes.

83. The intersecting and station points (74) of any original lines, lying in one plane, are points in the intersecting and station lines of that plane: and the vanishing points of the same original lines lie in the vanishing line of that plane; for the radials of the originals must lie in the vanishing plane of that in which the original lines lie: and these radials must form with each other, and with the parallel of the vertex, angles respectively equal to those which the original lines form with each other and with the intersecting or station lines.

84. The vanishing line and parallel of the vertex to any plane will be those also of all planes whatever which are parallel to the first: and the radial and vanishing point of an original line will be those also of all lines parallel to the first, whether they lie in one plane, or in different ones.

85. The perspective projections, or images, of any number of original parallel lines, will be either parallel lines, parallel to the originals (73), or will be lines passing through the respective intersecting points of those originals (77), and through their common vanishing point; and the points in which the indefinite images of original lines, not parallel, cut one another, will be those of the points in which the originals cut one another.

86. It has been shown that the image of a line is parallel to that line's director; if, therefore, two or more lines have a common station point, and consequently a common director, or if the station points of two or more lines lie in one director, the images of those lines in either case will be parallel lines; and in these cases only can original lines, not parallel, have parallel images.

87. The ratios which exist between the definitive images and the original segments of lines are easily deducible, either geometrically or analytically; but as these theorems do not lead to rules of frequent practical utility, we forbear, with one or two exceptions, entering into them. Let B″ B represent a finite portion of an original line, bisected by the point B′, then the rays V B″, V B′, V B, and the radial V P of B″ B, will be harmonical lines; the definite image of the original line will consequently be harmonically divided by the images b', b, of B′ and B, and by the vanishing point P. Conversely, if any segment of an indefinite image of a line be bisected by a point, the segment of the original line between its station point and the original of the image farthest from that station point will be harmonically divided by the originals of the other two points. If the point which bisects a finite line A B be the station point of that line, the image $a\,b$ of A B will be bisected by the vanishing point P.

88. If an original finite line A B be parallel to the plane of the picture, its image $a\,b$ will be to A B in the ratio of the *distance of the picture* (70) to the perpendicular distance of the plane, parallel to the picture in which A B lies from the vertex; and if A B be divided by a point D in any ratio, the image $a\,b$ will be divided by d, that of D in the same ratio.

89. If an original plane figure be parallel to the plane of the picture, the image of that figure will be similar to the original; its periphery will be to that of the original, in the ratio of the *distance of the picture* to the perpendicular distance of the plane of the original figure from the vertex; and the area of the image will be to that of the original, as the squares of these lines. If, therefore, the distance of the picture be equal to that of the original parallel plane from the vertex, the image of an original figure in that plane will be equal, as well as similar, to the original: this may occur if the original plane coincide with that of the picture, or if the vertex be at equal distances from both, and lie between them; or if the vertex be infinitely and therefore equally distant from both on the same side.[*]

90. If an original plane, or planes, be parallel to the plane of the picture, their vanishing plane will coincide with the vertical plane: no such planes can therefore have any vanishing line.

91. If an original plane, or planes, be perpendicular to the plane of the picture, their vanishing plane will pass through the distance of the picture (70); consequently the vanishing line of such plane, or planes, will pass through the centre of the picture.

92. If an original plane pass through the vertex, its vanishing plane will coincide with it; the intersecting and vanishing lines will therefore coincide in one, as will also the station lines, and parallel of the vertex; and the images of all lines and plane figures, in such an original plane, will coincide in one line, that in which the plane itself cuts the plane of the picture.

93. The vanishing planes of two original planes will form the same dihedral angle that the original planes form with each other, and the line in which the vanishing planes intersect will pass through the vertex and be parallel to that in which the original planes intersect each other; it will, therefore, be the radial of this latter-named intersection. The intersection of the two vanishing planes, or this radial, will cut the plane of the picture in the vanishing point of the intersections of the original planes, which vanishing point will obviously be the intersection of the two vanishing lines determined by the two vanishing planes.

94. It follows, therefore, that the line in which two original planes cut one another will have for its vanishing point that in which the two vanishing lines of the original planes cut each other, and that the intersecting point of the common intersection of two original planes will be that in which the intersecting lines of those planes cut each other.

95. Every vanishing plane is supposed to have an *auxiliary* one, perpendicular both to it and to the plane of the picture, and therefore passing through the distance of the picture: this auxiliary vanishing plane will cut the plane of the picture in an *auxiliary vanishing line* perpendicular to the principal one, and passing through *its centre*, and also perpendicular to the intersecting lines of the original planes. The line in which the auxiliary vanishing plane cuts the principal vanishing plane is termed the *principal radial* of the original plane, or planes, to which the vanishing plane pertains. This principal radial is obviously perpendicular to the principal vanishing line, and meets it in its centre, which will consequently be the vanishing point of all lines in the original planes perpendicular to their intersecting lines.

96. The principal radial will form, with the distance of the picture and with the auxiliary vanishing line, angles equal respectively to the complement of the angle, and to the angle itself, which the original planes make with the plane of the picture.

97. The *auxiliary radial* of any vanishing plane is one lying in the auxiliary vanishing plane, and perpendicular to the principal radial; this auxiliary radial is that of all lines perpendicular to the original planes, the common vanishing point of which is the point in which the auxiliary radial meets the auxiliary vanishing line. This auxiliary vanishing point is the image, or projection of the points in which the auxiliary radial intersects all the original planes to which the principal vanishing plane is common.

98. The auxiliary vanishing plane, being perpendicular to the original planes, as well as to their vainishing plane, and to the plane of the picture, will intersect those original planes in lines perpendicular to their intersecting lines, and parallel to their principal radial.

99. It follows from these definitions, that the vanishing lines of all planes perpendicular to one or more parallel original planes will pass through the auxiliary vanishing point of those planes.

100. If the original plane, or parallel planes, be perpendicular to the plane of the picture, their principal radial will coincide with the distance of the picture. Their auxiliary radial will be parallel to the plane of the picture; and the vanishing lines of all planes, perpendicular to the original planes, will be parallel to each other, and perpendicular to the vanishing line of the original planes.

101. If a circle be supposed, described in an original plane on the point, as a centre, in which the auxiliary radial cuts that plane, all lines touching that circle will be intersections with that original plane, of vanishing planes of other original planes, inclined to the first in a certain angle. The point in which any one of these tangents to the circle cuts the intersecting line of the first original plane will therefore be a point in the vanishing line, to be determined by each such

---

[*] We shall continue to employ the same conventional notation as before, designating an original point and line by capital letters, and their images by small, thus $a\,b$ is the image of A B, and so on.

[*] From this theorem the relation between perspective projection, and projection on a co-ordinate plane by parallel lines, either perpendicular or oblique to that plane, will be at once perceived; the latter being the *limit* of the perspective image, as the vertex of the converging rays may be supposed to become more and more distant from the original: or the former may be considered as a perspective projection, the vertex being at an infinite distance.

vanishing plane respectively, while the vanishing point of each such intersection in the original plane will be a second point in the vanishing line of the plane inclined to the former. Therefore this vanishing line will be determined, if these two points be found.

102. For if a right conical surface be imagined formed round the auxiliary radial as an axis, having the vertex for its apex, and its side forming with that axis the complement to the angle the secondary original planes form with the first; the vanishing planes of these secondary original ones will touch that conical surface in a line, which will be the principal radial of each such vanishing plane; and therefore each vanishing plane will cut the first original plane in a line tangential to the circular section of the conical surface by that original plane. Again, the point in which these tangents to the circular section cut the intersecting line of the first original plane, will be common to the intersections with the plane of the picture of each vanishing plane respectively, or to the vanishing line as above stated.

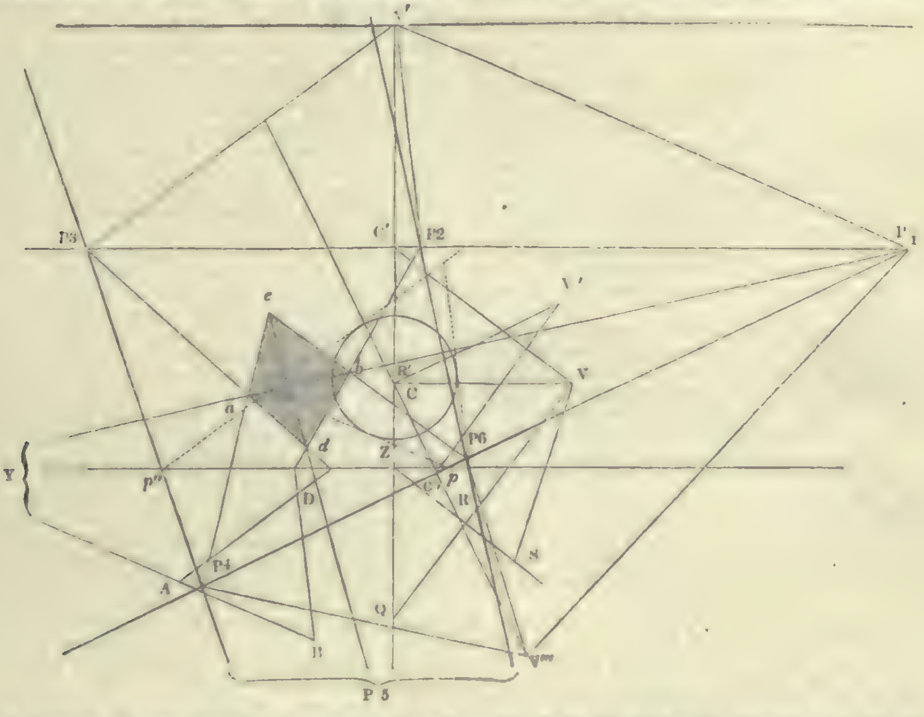
103. Constructions can be made, founded on these general theorems, by which the perspective projection of plane figures, or solids, may be obtained on a plane, taken to represent the plane of the picture, and all other original or vanishing planes brought to coincide with it by being turned round on their intersections with each other, and with the assumed plane of the picture.

104. If an original plane be supposed turned round on its intersecting line till it coincide with the plane of the picture, the relations of lines in the plane to each other, and to the intersecting line, will not be affected by so doing. And if the vanishing plane of that original plane be also turned round on the vanishing line in the *same* direction, the same observation will apply to the radials of original lines in the original plane, which will preserve their original relative position to that vanishing line: these radials will be therefore parallel to the original lines respectively, when both they and the original lines are brought into the same plane.

105. Since the principal radial is perpendicular to the vanishing line, this radial will coincide with the auxiliary vanishing line when the vanishing plane is brought into the plane of the picture.

106. But if, as frequently occurs, the constructions must be made on the supposition that the original plane has been turned round on its intersecting line in one direction, and the corresponding vanishing plane turned round on its vanishing line in the contrary direction; the radials will not be parallel to the original lines on this supposition, when the two planes coincide in one. These radials must therefore be drawn, making the same angles with the parallel of the vertex and with the auxiliary vanishing line, that the original lines make with the intersecting line, and with lines perpendicular to it.

107. As an example of the application of the foregoing principles, let it be required to draw the perspective projection of a tetrahedron, of a given magnitude, its position with respect to the vertex and the plane of the picture being also given or assumed.



108. Draw Y Z * at pleasure, to represent the intersecting line of one plane of the solid; and take any point C for the centre of the picture. Through C draw C V′ perpendicular to Y Z for the auxiliary vanishing line of the plane (95), also draw C V parallel to Y Z, and equal to the given distance of the picture (70); this, and the following steps in the construction, being founded on the supposition of the auxiliary vanishing plane (95) being turned round on C V′, till it coincide with the plane of the picture. Make the angle C V C′ equal to the complement of that at which the plane of the tetrahedron is assumed to be inclined to the plane of the picture (96), V C′ will be the principal radial of the plane, and C′ the centre of its vanishing line; consequently a line, $P_3 P_1$, drawn through C′, parallel to Y Z (82), will be that vanishing line. Draw V Q, perpendicular to V C′, for the auxiliary radial, cutting V C′ the auxiliary vanishing line, in Q the auxiliary vanishing point of the plane of the original tetrahedron.

109. Draw Z R parallel to V C′ for the intersection of the auxiliary vanishing plane with the original one; R therefore, in which Z R meets V Q, will represent the point in which the auxiliary radial meets the original plane.

110. Make C′ V′ in that line equal to C′ V, and through V′ draw a parallel to Y Z, which will represent the vertex and its parallel (81) brought into the plane of the picture by the turning of the vanishing plane on the vanishing line $P_3 P_1$.

111. Draw the equilateral triangle A B D for the face of the tetrahedron in its given or assumed position with respect to the intersecting line of its plane and the centre of the picture: this construction implies that the original plane of that face has been turned round on Y Z, in the same direction the vanishing plane was turned round in, on $P_3 P_1$. Through V′ draw the radials of the sides of the triangle parallel to them, and cutting the vanishing line in P_1, P_2, P_3, the vanishing points of those sides; the perspective images of which being drawn through the intersecting and vanishing points of the sides respectively, will form the image *a b d* of the given face.

112. If the original triangle had been assumed as lying between the intersecting and station lines of its plane, A B C would have been above the former line, and its image *a b d* below it; if that plane be supposed turned round in the same direction.

If rays be drawn from V′ through A, B, and D, they will be found to pass through the images *a*, *b*, *d* of those points, and recourse must frequently be had to this mode of determining the image of a point in a line, when circumstances prevent the possibility of determining it by means of the image of another line, also passing through the original point. Or if the distances of any points in a line, as A, B, from its intersecting point, be set off from that point along the intersecting line, and the radial of the line be laid off along the vanishing line, from the vanishing point, of the original line; then lines drawn from the former points in the intersecting line to the point in the vanishing line, will cut the image of the original line in those of the points A, D.*

---

* In this and some subsequent figures, the bracket with a letter to it is intended to signify that that letter applies to the point of convergence of the lines thus indicated; as for example in this figure, P_5 refers to the point in which P_3 P_4, and P_2 P_6 would meet. It must be observed also, that reference is in some places made to lines or points, not shown in the figures, to prevent confusion.

* Let Y be the intersecting point of an original line Y A, and P its vanishing point, Y P being its indefinite image; then if Y A and P V be drawn in any, whatsoever, but opposite directions, parallel to each other, Y A being made

113. By one or other of these principles, the images of any definite right lines, and therefore of any rectilinear figure, may be obtained. For one or more original lines may be always assumed as passing through one or more points, the images of which are required; so that the indefinite images of the assumed lines will give those of the points sought, by its intersections with the images of other lines, in which those points lie: and these assumed lines may be so taken as to define the images with more precision, or to obviate the necessity of drawing radials of lines but little inclined to the intersecting lines of the planes in which they lie. Z R is the perpendicular distance of the point in which the auxiliary radial cuts the original plane from its intersecting line; R therefore is the centre of the circular section of the conical surface before alluded to (102). Make Z R′ in Z V′ equal to Z R: draw V S to make at V, with V R, the complement of the angle at which the faces of the tetrahedron are inclined to each other. From R′, as a centre, with R S for a radius, describe a circle. Draw lines to touch this circle, parallel; respectively to A B, B D, A D. Through the point *p*, in which the tangent parallel to A B cuts Y Z, and through P_1, the vanishing point of A B, draw $P_1 P_4$, the vanishing line of the face of the solid meeting the face A B D in A B: and on the same principles $P_2 P_6$, $P_3 P_4$, the vanishing lines of the two remaining faces are found; then P_4, P_5, P_6, in which these vanishing lines intersect each other, will be the vanishing points (94) of the edges of the solid, and lines accordingly drawn from *a*, *b*, *d* to these points will complete the image of the tetrahedron.

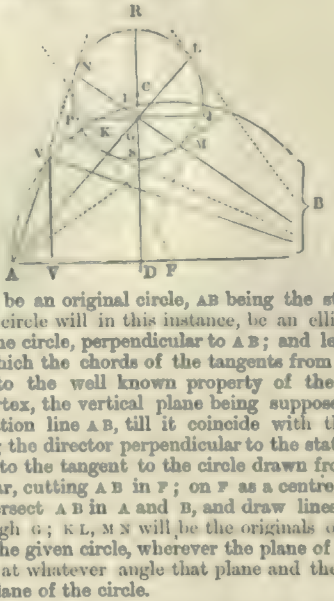
114. Simple as is the construction above described, for finding the vanishing lines of planes making any proposed angle with a given plane, it may frequently be avoided by availing ourselves properly of the symmetry of the solid to be delineated. Thus, in the example before us, after finding the image, *a*, *b*, *d*, of one face of the tetrahedron, we might have determined the image of the centre of that face by drawing those of the perpendiculars on each side of the triangle from the opposite angles; a line drawn through this centre and through Q would be the image of one, perpendicular to the plane of the triangle (97); this line would pass through the vertex of the pyramid, or through the angular point in which the other three faces meet, by finding the image of this point, which can be easily done by first determining the intersecting point of the perpendicular, and the intersecting line of any plane in which it lies; then lines drawn from *a*, *b*, and *d* to this image *e* would complete the figure.

115. When a vanishing line is obtained, it is frequently requisite to determine its centre and distance, or its principal radial; this is done by the construction employed to determine the vanishing line $P_1 P_2$. Thus, to determine the centre, &c., of vanishing line $P_1 P_4$, draw a parallel to it through C, making C V″ equal C V, the distance of the picture; also draw C V‴ perpendicular to the vanishing line for its auxiliary one, cutting the former in C″ its centre. Make C″ V‴ equal C″ V″, the principal radial; then V‴ P_1, V‴ P_2, V‴ P_4 being drawn, they will be the radials of the three sides, *a b*, *e b*, *e a*, of the face of the solid, and will be found, accordingly, to make angles of 60° with each other (83). The radial V‴ P_1 will also be found equal to V′ P_1, these lines representing one and the same line, only brought into the plane of the picture by the rotation of two different vanishing planes on their vanishing lines.

116. The perspective projection of a curve may always be found by means of the images of a sufficient number of points in the original, or by the projection of some inscribed or circumscribed polygon; if the curve be a plane one: in this case the image of a tangent to the original curve will be a tangent to the image of that curve. For if the image of the tangent meet that of the curve in more than one point, these points must be the images of points in the original curve through which the original of the tangent must pass: which is contrary to the supposition. But there are some theorems regarding the perspective projection of a circle, and constructions founded on them, which ought to be well understood by the draughtsman.

117. The rays from the circumference of a circle, obviously, form a conical surface, the section of which, by the plane of the picture, will be one of the conic sections. If the original circle, or base of the cone of rays, be parallel to the plane of the picture, the image will be a circle, the radius of which will be to that of the original in the ratio of the distance of the picture (70) to the distance of the plane of the original circle from the vertex (89).

118. If an original circle do not touch, or cut, the station line of its plane, its image will be an *ellipse* wherever the plane of the picture may be; unless the section by the plane of the picture happen to be a subcontrary one, an exception to which we shall recur on a subsequent occasion. If the station line be a tangent to the circle, its image will be a *parabola*; and if that line cut the circle, the image will be the opposite branches of an *hyperbola*, lying on contrary sides of the vanishing line of the original plane (80).



119. Let KNLM be an original circle, AB being the station line (81); the image of the circle will in this instance, be an ellipse. Draw the diameter C D to the circle, perpendicular to A B; and let G be the point in C D through which the chords of the tangents from all points in A B pass, according to the well known property of the circle. Let V represent the vertex, the vertical plane being supposed to be turned round on the station line A B, till it coincide with the plane of the circle; V V′ being the director perpendicular to the station line. Make D E, in D R, equal to the tangent to the circle drawn from D; bisect V E by a perpendicular, cutting A B in F; on F as a centre, with F V or F E for a radius, intersect A B in A and B, and draw lines through these points and through G; K L, M N will be the originals of the axis of the elliptic image of the given circle, wherever the plane of the picture may be assumed, and at whatever angle that plane and the vertical one be inclined to the plane of the circle.

120. If A, B be two points in A B, such that each is in the chord of the tangents from the other point produced, then, from the properties of the circle, A E, B E will be equal respectively to the tangents A N, B L, drawn from those points; and the square on A B is equal to the sum of the squares on A N, B L, or on A E, B E. E therefore lies in the circumference of a circle described on A B as a diameter. Since the angle A V B, made by the directors of A L, B N is a right angle by construction; the images of A L, B N will be perpendicular to each other, and parallel, respectively, to those of the tangents A N, A M; B L, B K having the same station points with the chords K L, M N. Again, since A L is harmonically divided in K and G, and B N in M and G, the image of K L will be bisected by that of G, and the image of M N will be also bisected by the image of G (87): hence those images being diameters to the ellipse, mutually bisecting each other, and parallel reciprocally to the tangents which are the images (86) of A N, A M, B K, B L, the images of K L, M N must be conjugate diameters, and since those diameters are perpendicular to each other, they must be the axes.

121. If V′, the foot of the director V V′, coincided with D, or if V V′ were in the auxiliary vanishing plane, the perpendicular to V E would be parallel to A B, and P Q, S R would be the originals of the axes, which accordingly would be parallel and perpendicular to the intersecting line. But in every other position of V V′, with reference to the circle, these axes must be oblique to that intersecting line, while the angles they form with it will vary according to the distance of V′ from D, and according to the length of the director V V′.

122. The points G and E will not be common to two or more concentric circles, the originals of the axes of the elliptic projections of concentric circles will not be in the same straight lines, nor will they have the same station points, except in the case of V′ and D coinciding, when the originals of the axes will be parallel and perpendicular to A B.

123. If A B touched or cut the original circle, the originals of the axes, &c., of the parabolic or hyperbolic projections might be found on the same principles: but as these curves do not often occur in practical perspective drawing, we shall not dwell on the subject.

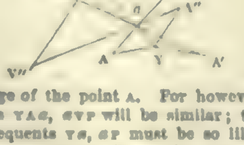
124. The only solids with curved surfaces that need be considered are, the cylinder, the cone, and the sphere.

125. If a line be conceived to pass through the vertex, parallel to the axis of a cylinder, whether right or oblique, two planes passing through this parallel will touch the cylinder in two lines of its surface, also parallel to its axis, which will be the originals of the straight outline of the perspective projection, or image, of that cylinder.

126. These two tangential planes will cut the plane of the base of the solid, or that of any section of it whatsoever, in two lines, which will be tangents to the curve of that section. And the parallel to the axis through the vertex is obviously the radial of that axis, which, by its intersection with the plane of the picture, will determine the vanishing point of that axis; and this vanishing point, it must be remembered, is the image of the point, in any original plane, cutting the cylinder in which the two tangents to the curve of the section in that plane meet, which have been shown to be the originals of the outline of the solid.

127. If therefore the image of the base or of any section of the

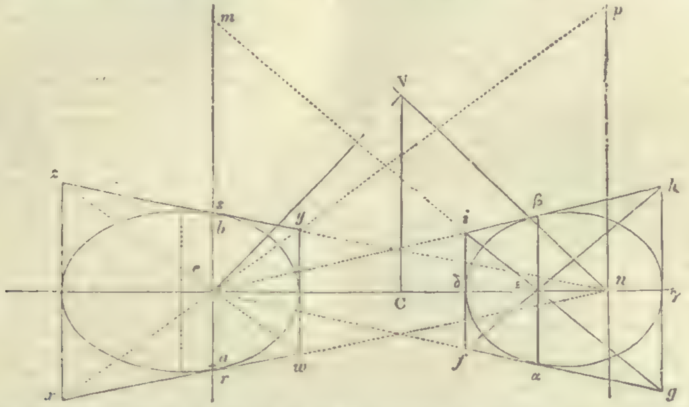
equal to the distance of a point A in the original from its intersecting point, and P V equal to the length of the radial of the line; then A, V being joined, A V will cut Y P in *a*, the image of the point A. For however the lines Y A, P V may be drawn, the triangles Y A *a*, *a* V P will be similar; the antecedents Y A, P V being constant, the consequents Y *a*, *a* P must be so likewise. When this principle is applied, the two parallels may be so taken that the line V A joining their extremities may cut Y P at nearly right angles, and so define the point with precision.



cylinder by a plane be obtained, lines drawn tangents to this image through the vanishing point of the axis will give the straight parts of the outline of the solid; these outlines must also be tangents to every other curve which is the image of any section of the original cylinder.

128. If a line pass through the vertex and the apex of a cone, and meet the plane of its base, or any other plane cutting the cone, two lines drawn through the point of intersection tangents to the curve of the section will be the intersections with that plane of two others passing through the vertex and tangential to the surface of the solid, and these two planes will touch the cone in lines which will be the originals of the outline of its image.

129. The ray just mentioned passing through the apex of a cone is analogous to the radial of a cylinder passing through the vertex, the cylinder being considered as a cone, with its apex infinitely distant.



130. If the line through the vertex and the apex of a cone, or the ray of that apex, be parallel to the plane of its base, or of any section, the tangents to the base lying in its plane, or in that of such section, must be drawn parallel to that ray, and the image of the apex will be the vanishing point of these parallel tangents.

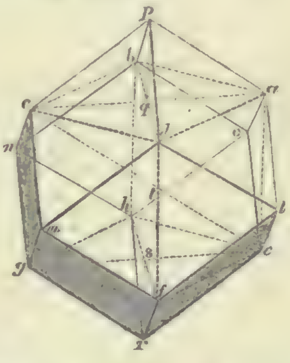
131. Let C be the centre of the picture; $a\,b$, bisected in e, being given as the image of a diameter, parallel to the plane of the picture, of a sphere * e, therefore being the image of its centre (88). Draw an indefinite line through C and e, and $\mathrm{C\,V}$ perpendicular to it, equal to the assumed distance of the picture; take any point ϵ at pleasure in $e\,\mathrm{C}$, but as far from e as convenient; draw $\alpha\,\beta$ through ϵ perpendicular to $\mathrm{C}\,e$, making $\epsilon\,\alpha$, $\epsilon\,\beta$, equal to $e\,a$, $e\,b$. Join $\mathrm{V}\,e$ and set off its length each way from e to l and m along a line perpendicular to $\mathrm{C}\,e$.

132. By this construction $l\,m$ is a vanishing line, of which e is the centre, $\mathrm{V}\,e$ equal to its principal radial, and $\mathrm{C}\,e$ its auxiliary vanishing line (95); l and m will obviously be the vanishing points of the diagonals of every square, lying in original planes having $l\,m$ for their vanishing line, the sides of that square being parallel and perpendicular to the intersecting line of its plane; accordingly the quadrilateral $f\,g\,h\,i$ is the image of such a square, lying in such a plane, and the line $\alpha\,\beta$ being made equal to the given image of a diameter of the sphere, $\alpha\,\beta$ and $a\,b$ are the images of equal original lines parallel to the picture and equally distant from it, or both lying in a plane parallel to that of the picture. If therefore an ellipse be described in $f\,g\,h\,i$, touching the sides in the points $\alpha\,\beta\,\gamma\,\delta$, and having its transverse axis in $\mathrm{C}\,e$, this ellipse will be the image of an original circle equal to a great one of the sphere, and having its plane parallel to that passing through the vertex and the centre of the sphere, or this original circle may be regarded as the oblique plan, on a plane parallel to it, of the section of the sphere by the vanishing plane, the projecting lines being parallel to the plane of the picture.

133. Draw $\mathrm{V}\,n$ perpendicular to $\mathrm{V}\,e$, cutting $e\,\mathrm{C}$ in n, and through n draw a vanishing line perpendicular to $e\,n$, or having $e\,n$ also for its auxiliary vanishing line; make $n\,o$, $n\,p$, each equal to the auxiliary radial $\mathrm{V}\,n$; make $e\,r$, $e\,s$,† in $l\,m$, each equal to the *semi-conjugate* axis of the ellipse last drawn, and complete the trapezium $w\,x\,y\,z$ as the image of a square having $o\,p$ for its vanishing line, and its sides parallel and perpendicular to the intersecting line of its plane. An ellipse described in $w\,x\,y\,z$, having its transverse axis in $e\,n$, will be the outline of the sphere.

134. For n being the auxiliary vanishing point of the plane of the original of $f\,g\,h\,i$, $o\,p$ is the vanishing line of all planes perpendicular to that original plane, and intersecting it in lines parallel to the plane of the picture. The original square of the quadrilateral $w\,x\,y\,z$ is therefore perpendicular to the plane of the original of $f\,g\,h\,i$, or to the vanishing plane passing through the vertex and centre of the sphere. Now it will be seen that the conjugate axis of the ellipse in $f\,g\,h\,i$ is the *oblique plan* (59) of the chord of the tangents from the vertex to the section of the sphere by the vanishing plane, which chord of the tangents must be a diameter of the small circle of the solid, constituting the original of its apparent outline; this small circle being the base of the cone of rays tangential to its surface (62), and having its plane perpendicular to that of the vanishing plane passing through the vertex and centre of the sphere; $w\,x\,y\,z$ is consequently the image of the square circumscribing the circular base, and the inscribed ellipse that of the circle itself, or this ellipse is the outline of the sphere.

135. If the distance of the vertex (70) be supposed to be indefinitely great, compared to the magnitude of the object to be represented, the pyramid of rays may be conceived to become a prism, or the rays to be parallel. On this supposition the vanishing points of the lines of the original object would be indefinitely distant from the centre of the picture, and the images of parallel original lines would be parallels. The isometric projection of a parallelopiped (57) is obviously a limited case of this kind, the limitation being necessary from the object in view, which induces us to adopt that kind of projection. But there are occasions on which it is desirable to delineate rectilinear objects pictorially, which from their small relative size, and from other considerations, do not require the application of perspective projection, and which would not be adequately represented by an isometric one. In such cases the draughtsman may readily accomplish his purpose by combining the principles of projection on co-ordinate planes with perspective, as in the following example.



136. Let a hexagonal figure, $a\,b\,c\,d\,e\,f\,g$, be drawn, with the condition that each pair of opposite sides shall be parallel, and consequently equal; from the angles a, c, f draw lines parallel to the alternate sides, and meeting in a point d, and from the intermediate angles b, e, g draw lines parallel to the remaining sides respectively, and meeting in h. The figure thus formed will be the *orthographic* or *orthogonal* projection of a cube, under certain unknown conditions of inclination of the plane of projection to the projecting lines, and of these to the original planes of the solid.

137. The projections of the centres of each face of the cube, as q, may be found by drawing the diagonals, as $a\,c$, $b\,d$, and if lines be drawn through the centres of each pair of opposite faces, as $p\,r$, which lines will obviously be parallel to the edges of the solid, and perpendicular to the planes of the faces, they will pass through the vertices of right pyramids placed on each face. By making the altitude of these pyramids, as $p\,q$, equal to half the projection of the parallel edges $b\,f$, &c., of the solid, we obtain the remaining angles, l, m, n, o, p, r, of the solid termed a rhomboidal dodecahedron, one diagonal of each face of which is one edge of the original cube.

138. By previously constructing the projection of a cube in the manner just described, the sides of which will furnish a scale of the ratio of the projections of any lines parallel to the edges of that cube, the projection of any parallelopiped may be obtained, and from this again the image of any symmetrical solid deduced. In this manner

---

* $a\,b$ need not be perpendicular to the line $c\,e$; it is shown so in the figure, to avoid unnecessary lines; but as every diameter of the sphere which lies in a plane parallel to that of the picture is also parallel to that plane, $a\,b$ may make any angle whatever with $\mathrm{C}\,e$.

† The points $r\,a$, $s\,b$, are not the same, though they cannot be distinguished in the figure.

the forms of crystals can be drawn with the most perfect accuracy, and a most distinct conception obtained of them and of the relative position of their planes. And by analogous constructions diagrams of the theorems of solid geometry may be drawn, which would greatly facilitate the study of analytical geometry.

139. It has been stated that perspective projection is principally employed to furnish a pictorial outline of a building, machine, &c., or to convey an idea of an object of that description to the spectator, but to do this the perspective outline must excite in his mind the ideas of the real forms of that object in their relative situations, such as would be excited by the object itself, when viewed from a given point. But there are limitations to the apparent forms of objects, arising from the structure of the eye and the laws of vision, which the draughtsman must never lose sight of, when he practically applies the purely geometrical principles we have deduced, or otherwise he may produce an accurate projection of an object which would be perfectly unintelligible to an ordinary spectator; as the outline of the sphere, deduced in the preceding example, would be to an uninitiated eye.

140. Since the eye can only embrace at one time a very limited field of view, in order to see the whole of an object without changing the place of the eye, the spectator must not be nearer to it than a certain distance, for otherwise he would have to turn his head to see the successive parts, and at each such change of position the apparent forms of those parts just escaping from his view would undergo a considerable modification, arising from the structure of the eye itself. Few persons are aware of these modifications, owing to the effects of habit and the result of the judgment, which induce us unconsciously to assign the real and constant forms we know the parts of the object to possess to the apparent forms under which those parts are seen. Indeed it requires a considerable degree of abstraction and education of the eye to make the mind cognisant of the fact, that it is never the real form of an object that presents itself, a truth familiar to artists, who know that persons when first attempting to draw an object before them by eye, invariably draw it as they know it to be, and not as they really see it.

141. We have stated that the perspective projection of an object is rarely viewed from the precise point from which alone it ought to be viewed, so that the forms in the projection may suggest the ideas of the original forms whence they were deduced; consequently the outline should not in any part deviate greatly from what we may call the average form under which the true one would present itself to the eye. To effect this accordance the draughtsman must assume his point of view, or *vertex*, at such a proportional distance from the object itself, or from the imaginary model of it, that the rays from the points of it farthest apart, may not contain an angle greater than 60° at most, and, if circumstances allow of it, of not more than 45°. In short the pyramid of rays from an object to the vertex should be included within a cone the angle at the apex of which is not greater than that above named.

142. The distance of the vertex from the object being determined from these considerations, and its position with respect to the various parts of the original object decided on, by the conditions of the kind of view of that object it is proposed to delineate, the position of the plane of the picture should, generally speaking, be perpendicular to the axis of the cone or pyramid of rays before alluded to; but the following principles must determine more accurately its situation.

143. From the frequency of their occurrence under circumstances favourable for the observation, the eye is accustomed to the apparent convergence of long horizontal parallel lines, as in streets, aisles of cathedrals, long avenues of trees, or walls, &c., but perpendicular parallel lines are rarely if ever long enough to cause this optical effect. Now we have proved that the projections of parallel lines never can be parallel unless the originals are parallel to the plane of the picture; if therefore the draughtsman were to assume that plane *not* parallel to the vertical lines of a building, &c., the convergence of the projections of these lines would offend the eye of a person looking at his drawing, as being at variance not only with his judgment of the real parallelism of the lines in question, but even with his daily uncultured observation. But there is another optical phenomenon regarding the appearance of long parallel lines, which we must briefly allude to, because it throws considerable light on the distinction between the apparent forms of objects as seen by the eye, which forms are functions of the angles solely under which the original forms are seen, and the figures on a plane, resulting from the section by that plane of the pyramids of rays from those original forms, which sectional forms are functions of the arcs subtending those angles.

144. If a spectator stand opposite two or more long horizontal parallel lines, as those of the façade of a long building, or of a garden wall, for example, he very palpably perceives the apparent convergence of these parallels in both directions, as they recede from him to the right and left; on reflection, he is therefore convinced that the apparent form of the really parallel straight lines are curves, produced by the varying angles under which the equal ordinates between the parallels are seen, as they become more and more distant from the eye.

145. The parallel projections of such long horizontal lines, which would result from the plane of the picture being assumed parallel to the originals, would reassume their natural apparent curvature, if viewed from the correct vertex; but if not, their parallelism would offend the eye as being at variance with daily experience, and still more would any attempt to draw on a plane the apparent curvature of the lines in question be reprehended as being contrary to the verdict of the judgment, which decides that the originals, being straight lines, ought not to be represented by curves.

146. The draughtsman, consequently, must never assume his plane of the picture parallel to the longest side of a building, &c., however much he may be tempted to do so from the facility of making his constructions under this condition, when the projections of such a side would subtend at the vertex an angle of more than 15° or 20°.

147. Keeping these conditions in view, the draughtsman may assume the distance of his picture, or its distance from the vertex, entirely according to his own convenience, since it is only the absolute magnitude of the image or projection which is altered by the different distances of the picture, the figure of the image being similar on all parallel planes, as long as the vertex and object remain the same. For the sake of facility of construction, he will generally assume his plane of the picture as coinciding with some principal vertical line of the object or model.

148. The *shadow* of any object is obviously the *projection* of it on a surface, by converging on parallel lines or rays, according as the luminary is supposed to be at a finite or at an infinite distance, as the sun may be considered to be as regards terrestrial objects. When, therefore, we have obtained the projection of an object by the principles just explained, they will also enable us to obtain the projection of its shadow on one or more planes or surfaces, as supposed to be cast by an artificial light or by the sun; the problem being simply to determine the projection of the intersection of a pyramid or prism of rays passing from a given or assumed point through the points of a projected object.

149. If the object be *perspectively* projected, and the luminary be the sun, the vanishing point of the parallel rays, whose direction must be given or assumed, will represent the sun, since that vanishing point is the image of a point infinitely distant.

150. Although our power of forming correct conceptions of the true form of an object, as derived from a projection or pictorial representation of it, is much increased by the addition of light and shade, and of shadows of the object correctly projected by rules identical with those by which its outline was obtained, yet as soon as we thus approach the domain of a higher art, that of painting, the mathematical precision of the shadows we should obtain by our rules must yield to more important considerations connected with the art alluded to. Hence it is that the draughtsman seldom applies the geometrical principles for finding the true shadows of the engine, building, or analogous object, the outline of which he has delineated; for at an early stage of his practice in drawing he ought to have acquired sufficient knowledge of art to be able to add to his outline the effect of light and shade without any gross violation of truth of nature, and with a better pictorial effect than he could ensure by geometrical rules. We shall consequently only give two simple examples relating to the projection of shadows, rather as affording additional illustrations of the principles of projections, than for any practical utility as regards the specific subject of shadows.

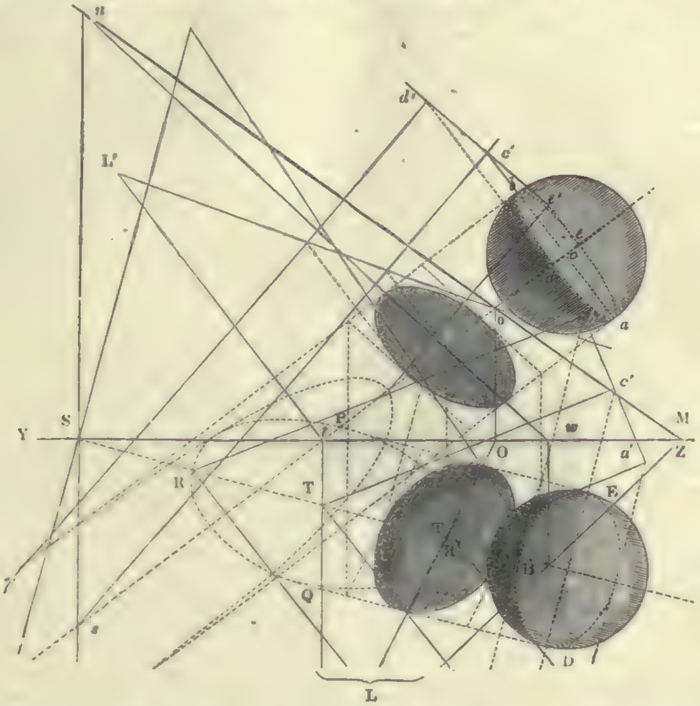
151. Let the line C S, $c\,s$, passing through the centre C, c, of a sphere, be given as the direction of the solar rays; it is proposed to determine the shadow of that sphere on the given plane L M N. It is obvious that the problem is to determine the section of the right cylindrical surface, formed by the system of parallel rays, which are tangential to the spherical surface, by the plane L M N; and that the great circle of the sphere passing through the points in which these rays touch it will be the base of the cylinder, and the boundary between the illuminated hemisphere and that in shadow.

152. Draw $c\,c'$, $C\,c'$, perpendicular to the projections of the ray, and make them respectively equal to the distances of the centre of the sphere from the co-ordinate planes; $C's$, $c'\,T$, drawn through the points in which the given ray cuts the co-ordinate planes, will represent that ray brought into the co-ordinate planes by the turning round of its projecting planes on its projections; draw $a'\,b'$, $d'\,e'$, perpendicular to $c'\,T$, $c'\,s$, making them equal to the diameter of the sphere; then lines drawn through a', b', parallel to $c'\,T$, will represent the two rays, touching the surface of the solid and lying in the projecting plane of the given ray brought into the co-ordinate plane along with that ray: these lines will cut C T in Q R, the vertices of the major axis of the elliptic outline of the shadow of the sphere on the co-ordinate plane. The conjugate axis Q P will be given by drawing lines parallel to C T tangents to the projection of the sphere; for these last parallel tangents will be the boundaries of the projections of the cylinder of rays. Lines drawn through a', b', parallel to $C\,c'$, will cut $c\,T$ in the vertices A, B, of the conjugate axis of the elliptic projection of the great circle, separating the illuminated hemisphere from that in shade; a diameter D E to the circular projection of the sphere, drawn through c perpendicular to C T, will be the major axis of this ellipse.

153. For the plane of the great circle, of which A D B E is the projection, is obviously by the construction perpendicular to the given ray, and the plane of this circle is cut by the projecting plane of the given ray C T in the original of A B, while the diameter D E is the projection of the intersection with the plane of the same great circle, by a plane passing through the given ray C S, $c\,s$, and perpendicular to the plan-

projecting plane (9) of the given ray. This perpendicular plane must, therefore, be the elevation-projecting plane of the given ray.

154. By the same construction applied to the other projection, the elliptic elevation $adbe$, of the circle separating the light and shade on the sphere, and the elliptic shadow of the sphere on the vertical co-ordinate plane, may be obtained.

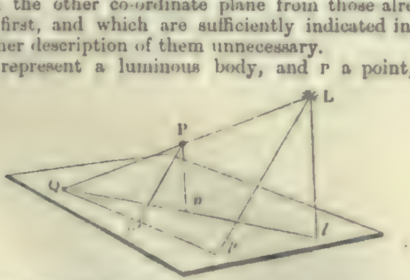


155. It is clear that in this example the two elliptic outlines of the shadows of the sphere on the co-ordinate planes, must cut Y Z in two common points; because the segments of the ellipse on either side of Y Z of each outline is the projection on the one co-ordinate plane of that portion of the cylinder of rays which forms on the other co-ordinate plane the portion of the outline of the shadow on the same side of Y Z. t L, perpendicular to Y Z, is the trace of the elevation projecting plane of C S, $c\,s$; o, O, is the point in which this same plane cuts the trace of the given plane, consequently L O is the plan of the intersection of those two planes, and T', in which this line is cut by the plan of the ray C S is the intersection of that ray, and the given plane; the elevation t' of the same intersection may be obtained by applying the same constructions to the other traces and projections.

156. The two pair of parallel planes, which are respectively perpendicular to the co-ordinate planes, and therefore to each other, and which are parallel to the given ray, touch the sphere in the points A, a; B, b; D, d; E, e. These four planes will be cut by the plane L M n in a parallelogram, the sides of the projections of which must be parallel to those of the ray C S, c, s, and to the lines L O, $w\,n$. Draw t L' perpendicular to $o\,t$, and make t L' equal to t L; join o L', which will represent the intersection of the projecting plane with L M n; draw lines through d', e', parallel to $c'\,s$, and from the points in which these parallels cut o L' draw parallels to L' t to cut $o\,t$; again lines drawn through these last intersections parallel to $w\,n$ will be the two sides of the elevation of the rectangle above mentioned; the parallel tangents at a and b will complete the figure; and $o\,t$, $w\,n$, will cut the opposite sides in the points in which the elliptic outline of the shadow of the sphere will touch those sides, or the points which represent the shadows of d, e, a, and b.

157. The plan of this parallelogram may be determined in the same manner, or by the other constructions explained for determining the projections on the other co-ordinate plane from those already determined on the first, and which are sufficiently indicated in the figure to render further description of them unnecessary.

158. If L represent a luminous body, and P a point, then, by



imagining a plane to pass through them, the intersection of that plane with the plane on which the shadow is cast will cut the ray L P in Q, the shadow of the point. To determine this intersection, we have only to draw two parallel lines through L and P, in *any* direction, and determine the points l and p, or l', p', in which these parallels meet the plane of the shadow: then $l\,p$, L P being drawn, they will cut each other in Q, the shadow of the point. This is the principle employed in the following construction.

159. Let $a\,b\,c\,d\,e\,f\,g$ be the perspective projection of a cube, C being the centre of the picture, C V the distance of the picture, P, X the vanishing line of the face $a\,b\,c\,d$, and Y Z its intersecting line; while Y' Z' is that of the face $e\,f\,g$, parallel to the former. Let Y Z and W Z be given as the vanishing and intersecting lines of a plane, on which the shadow of the cube, as cast by the luminous * body given in position, is to be determined.

160. X Z, X W, being drawn, will represent the lines in which the plane of the shadow intersects those of the parallel faces of the solid (94). If we suppose planes parallel to that of the picture to pass through the various points of the cube, as a, these will intersect the two original planes in lines, as $a\,a$, $a\,a'$, parallel to Y Z, Z W; and a line, $a\,a'$, through the point of the cube, parallel to the auxiliary vanishing line, will meet $a\,a'$ in the point a',* which will be the oblique projection of the point a on the plane of the shadow. Therefore, by drawing lines through the points a, b, c, d, parallel to Y Z, to cut X Z in $\alpha, \beta, \ldots \delta$, then lines parallel to W Z, through $\alpha, \beta, \ldots \delta$, will cut lines parallel to W C', drawn through a, b, c, d, in the oblique projections of those points on the plane of the shadow, and by referring e, f, g … to W X, in the same way, we obtain the oblique projections of the other angles of the cube.

161. Since the sides of the cube $a\,b$, $c\,d$, $e\,f$, &c., are parallels, their oblique projections will be parallels (59), consequently the images of these parallels $a'\,b'$, $c'\,d'$, $e'\,f'$, &c., will have a common vanishing point P' in the vanishing line of the plane in which the oblique projections lie; for the same reason, $a'\,d'$, $b'\,c'$, $f'\,g'$, &c., will have a common vanishing point P'_2 in Y X. Now it is obvious that the vanishing points P'_1, P'_2, are, by an extension of the principle, the oblique projections on the plane of the shadow of the vanishing points P_1 P_2 of the original sides of the cube; consequently the former may be determined from the last-named vanishing points by simply drawing lines through them parallel to W C to cut Y X in P'_1, P'_2.

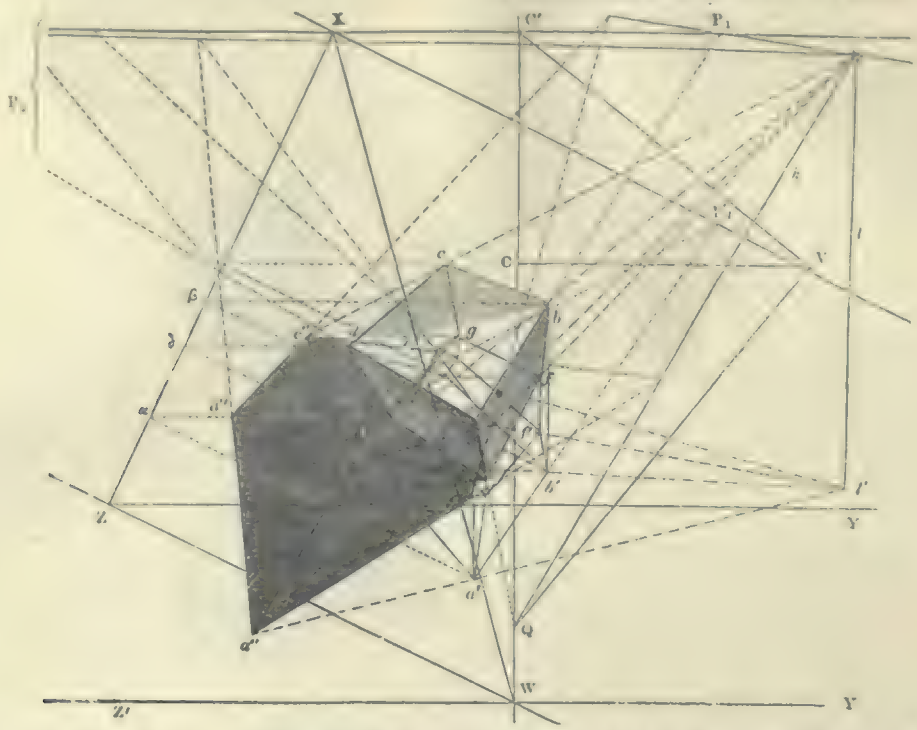
162. If k had been given as the image of the point in which a line through the luminary perpendicular to the plane Y Z met that plane, the image * of the luminary would be determined by making k *, drawn to the auxiliary vanishing point Q, the image of the given perpendicular height of the luminary above the original plane. A line through * parallel to W C' will meet C' k produced in l, the oblique projection of the luminary on the plane Y Z.* Its oblique projection l' on the plane of the shadow may be either determined as those of a, b, c, d, &c, were, or by drawing a line, as $a\,l$, at pleasure, to cut the vanishing line X P in some vanishing point; this vanishing point may be transferred to X Y by a parallel to C W; then a line drawn through a', the oblique

---

* That is to say, a' is the *perspective image* of the oblique projection of the original point of which a is the perspective image.

projection of a, to this transferred vanishing point, will cut $^{*}l$ produced in l', the oblique projection of the luminary on the plane of the shadow.

163. Draw lines through l' and through the oblique projection a', b', c', d', e', &c., intersecting each such line by the luminous ray $^{*}a$, $^{*}b$, $^{*}c$, &c., in the shadows a'', b'', c'', &c., of the angles of the cube,



and these points being joined, the figure thus produced will be the image of the shadow of the cube on the plane as proposed.

164. The oblique projecting lines $a\,a'$, &c., were assumed parallel to the picture and its auxiliary plane, simply for facility of construction, or else the points a, b, c, e, f, &c., might, as well as the luminary, have been projected on the plane of the shadow by lines in any direction, provided these lines were parallels according to the above principle (158).

165. Draw lines through * and P_1, P_2, and Q, the vanishing points of the sides of the cube; then the images, as $a''b''$, $c''d''$, $e''f''$, of the shadows of the parallel lines of the original solid will meet in a point in the corresponding line drawn through * and the vanishing point of those originals. For the planes passing through * and the parallels ab, cd, ef, &c., must intersect in a common line, passing through * and parallel to those originals: this common intersection will therefore have the same vanishing point, P_1, as those originals; the line $^{*}\text{P}_1$ represents that common intersection. Now the shadows $a''b''$, $c''d''$, $e''f''$ are the intersections of the before-mentioned planes by another, namely, by the plane of the shadow, and these intersections, $a''b''$, $c''d''$, &c., must meet each other in a point in $^{*}\text{P}$, the common intersection of the planes passing through * and the original lines. The same reasoning applies to the other shadows of the corresponding parallel sides of the cube.

PERUVIAN ARCHITECTURE. Remains of ancient Peruvian buildings are dispersed over the western parts of South America, from the equator to 15° S. lat., especially over the Montaña. Nothing certain is known of their date, but the oldest is attributed to Manco Capac, the traditional founder of ancient Peruvian civilisation, who is said to have flourished about three centuries before the conquest of Peru by the Spaniards, or 1200 A.D. These remains are characterised by simplicity, symmetry, and solidity. There are no columns, pilasters, or arches, and the buildings exhibit a singular uniformity and a complete want of all exterior ornaments. The structures, whether mere walls or buildings, are all of stone; the blocks in some instances being squared and laid in horizontal courses, in others consisting of huge polygonal masses; while in both the doorways and openings for light are formed of jambs inclined towards the top, and covered with a large stone as a lintel; being, in fact, in all respects almost the exact counterpart of the Pelasgian masonry of Greece and Italy [Pelasgian Architecture]—a circumstance the more remarkable since, if Peruvian tradition be not altogether at fault, some eighteen centuries must have elapsed between the latest example of Pelasgic construction in Europe and the earliest in Peru.

The great road of the Incas, which runs from Quito to Cuzco and the table-land of the Desaguadero, is made of enormous masses of porphyry, and it is still nearly perfect in several parts of the Montaña. Humboldt obtained an ancient Peruvian cutting instrument, which had been found in a mine not far from Cuzco: the material consisted of 94 parts of copper and 6 of tin, a composition which rendered it hard enough to be used nearly like steel. With instruments made of this material the Peruvians cut the enormous masses of which their buildings were composed. Some of the buildings near Cuzco contain stones 40 feet long, 20 feet wide, and nearly 7 feet thick. These stones are fitted together with great skill, and, as it was supposed, without cement. But Humboldt discovered in some ruins a thin layer of cement, consisting of gravel and an argillaceous earth; in other edifices, he says, it is composed of bitumen. These stones are all parallelopipedons, and worked with such exactness that it would be impossible to perceive the joinings if their exterior surface were quite level; but being a little convex, the junctures form slight depressions, which constitute the only exterior ornament of the buildings. The doors of the buildings are from 7 to 8½ feet high. The sides of the doors are not parallel, but approach each other towards the top. The niches, of which several occur in the inner side of the walls, have the form of the doors.

The walls of Cuzco are formed of huge polygonal blocks of limestone, from 8 to 10 feet in length, and the same in width, and admirably fitted to each other without cement, precisely like those shown in the cut of the Walls of Epirus in Pelasgian Architecture; but it is remarkable that not only is the masonry almost perfect of its kind, but that the walls are planned as fortifications with a degree of skill that excites the highest admiration of the military engineer.

The oldest known building in Peru is that called the house of Manco Capac, which stands on an island in the lake of Titicaca. It is built of rather small irregular polygonal blocks of stones; is curvilinear in plan and has small rude towers. The interior is divided into small square rooms, which are lighted only from the doorways. Not far from it is a later and less rude building of two stories, known as the House of the Virgins of the Sun. It is nearly square in plan, and is divided into twelve small square rooms on each story, those on the ground floor being lighted by the doorways, and those above mostly by very narrow windows, but some are without any opening or light.

The most extensive Peruvian buildings occur in the table-land of Cuzco, which was the most ancient seat of the monarchy of the Incas. There are also ancient remains within the boundaries of the present republic of Ecuador. Near the ridge called Chisinche, not far from the volcano Cotopaxi, are the ruins of a large building called the Palace of the Incas. It was a square, of which each side was about 30 yards long, and it had four doors. The interior was divided into eight apartments, three of which are still in tolerable preservation. Not far from the mountain-pass of Assuay is a building called Ingappilca, or the Fortress of Cañar, consisting of a wall of very large stones, about 5 or 6 yards high; it has a regular oval form, of which the greatest axis is nearly 40 feet long.

In the ruins of the town of Chulcanas, in the department of Truxillo, near the boundary-line between Peru and Ecuador, Humboldt had an opportunity of observing the construction of the private buildings of the Peruvians, and he observes that they consist of one room only, and that probably the door opened into a court-yard.

Of the ancient Peruvian tombs, the majority are square in plan: have the burial-place in the basement; a small chamber above, the door to which, at some height from the ground, is the only opening into the tomb; and flat roofs. Some of the tombs appear to have had domicular roofs; and remains of a few tombs occur circular in plan.

PERUVIC ACID. A colourless, inodorous, crystalline acid, formed by acting upon guanine by a mixture of chlorate of potash and hydrochloric acid.

PERUVIN. [STYRONE.]

PESTILENCE is a general term applied to those diseases of an epidemic character which affect large masses of a population, and are remarkable for their destruction of human life. The two forms of disease to which this term is most frequently applied, are plague and Asiatic cholera.

Plague is a disease of so fatal and malignant a nature, that to this very circumstance it probably owes its nomenclature. The nosological definition of this disease by Dr. Cullen is perhaps as correct as can be given in few words:—"A typhus fever, in the highest degree contagious, and accompanied with extreme debility. On an uncertain day of the disease, there is an eruption of buboes or carbuncles." Dr. Patrick Russell, who practised at Aleppo during the plague of 1760-1-2, informs us that its progress at its commencement is much the same in the several parts of the Levant as in the cities of Europe. It advances slowly, fluctuating perhaps for two or three weeks; and although at that period it generally proves fatal, yet it is often unattended by its characteristic eruptions. Indeed the cases in which the eruption is wanting constitute the most rapidly fatal type of the disease. The general derangement of the system which ushers in an attack of the plague, is much like that which commences the course of ordinary fever. A sense of cold, with some shivering, which is soon followed by heat and acceleration of the pulse, with giddiness, headache, depression of strength and spirits, white tongue, vomiting or diarrhœa, and great oppression about the præcordia, are among the first symptoms of the disease. These are succeeded by a burning pain about the pit of the stomach; by a peculiar muddiness of the eyes; by coma, delirium, and other affections of the sensorium, which terminate by death in some cases on the second or third day, before the pathognomic symptoms, buboes and carbuncles, have appeared. In other cases these last mentioned symptoms are present, together with purple spots and ecchymoses, which belong to the plague in common with other malignant fevers. Though these are the ordinary symptoms of plague, they are not invariably observed in the same individual; but many varieties occur, which chiefly have reference to the greater or less virulence of the disease, and the absence or presence of some particular symptoms. Thus, we are informed by Sydenham that in the infancy of the great plague of London scarce a day passed but some of those who were seized with it died suddenly in the streets, without having had any previous sickness; the purple spots, which denote immediate death, coming out all over the body, even when persons were abroad about their business; whereas after it had continued for some time, it destroyed none, unless a fever and other symptoms had preceded. Dr. Russell describes six classes or varieties of plague, in some of which the fever appears to have been very violent, while in others it was proportionally mild. The most destructive forms of the disease, according to this author, were marked by severe febrile symptoms; and the infected of this class seldom or never had buboes or carbuncles. The bubo however was the most frequent concomitant afterwards; carbuncles, on the contrary, were remarked in one-third of the infected only, and were seldom observed at Aleppo earlier than the month of May, near three months after the disease began to spread. The carbuncle increased in the summer, was less common in the autumn, and very rarely was observed in the winter. The absence of bubo and carbuncle at the commencement of the plague has been one of the grounds of contention among writers as to the real nature of the disease. Diemerbroech and some others assure us that no one symptom is pathognomonic of plague, and Dr. Russell concludes that "the plague, under a form of all others the most destructive, exists without its characteristic symptoms, can admit of no doubt." From all the evidence upon this subject that we have been able to collect, it plainly appears that authors are by no means agreed on the existence of the plague as a distinct disease. The symptoms, morbid changes, history, and mode of propagation of plague, bear so close a resemblance to those of the malignant typhus of this country, that it is difficult to regard them otherwise than as types of the same disease. This opinion is strengthened by the authority of Dr. Mackenzie, who resided thirty years at Constantinople. "The annual pestilential fever of that place," he observes, "very much resembles that of our gaols and crowded hospitals, and is only called plague when attended with buboes and carbuncles." Sir John Pringle too observes, "that though the hospital or gaol fever may differ in species from the true plague, yet it may be accounted of the same genus, as it seems to proceed from a like cause, and is attended with similar symptoms." The buboes which characterise plague consist of inflammatory swellings of the glands in the groin and armpits; the parotid, maxillary, and cervical glands sometimes, but less frequently, become affected. These buboes may either suppurate or gradually disperse: when suppuration occurs, it is seldom till the fever has begun to abate, and is manifestly on the decline, as about the eighth or ninth day. Carbuncles consist of inflamed pustules, or angry pimples, which, instead of suppurating, frequently terminate in mortification. They may be seated on any part of the body.

The morbid changes that are met with in the bodies of those who die from plague are very similar to what we find in typhus, yellow fever, and in the carcases of animals that have died in consequence of a putrid matter injected into their veins. The vessels of the brain and its membranes are gorged with a dark coloured blood; the lungs and liver present traces of inflammation or of gangrene; patches of inflammation and ulceration are met with in the stomach and intestines; the heart is of a pale red colour, easily torn, and full of black blood, which, according to M. Magendie, never coagulates. These changes however are not always found, and the same absence of appreciable organic lesion is sometimes observed in typhus and other diseases which prove rapidly fatal. No age, sex, or profession appears to enjoy an immunity from plague, nor does one attack secure the individual from future infection; but it has been observed that old persons, women, and children suffer less frequently and severely from its attacks than robust adults. Some persons also, who exercise particular trades, as knackers, tanners, water-carriers, bakers, and oilmen, seem to share this advantage; while smiths and cooks were noticed, during the campaign in Egypt, to be more particularly liable to it. One law appears to be universal in all plagues, namely, that the poor are the first and chief sufferers. In Grand Cairo, Constantinople, and Aleppo, it is in the low, crowded, and filthy parts of those cities, occupied by the poorest people, that the plague commits its greatest ravages. The celebrated plague of Marseille, in the year 1720, first appeared in a part of the city noted for the sordid filth, crowded state, and wretchedness of the poor inhabitants. This was likewise true of London, where, from the same circumstance, it obtained the appellation of the Poor's Plague. Like many other diseases, plague is observed in two forms: first, as an indigenous and local disease, peculiar to the inhabitants of certain countries, and from which they are never entirely free; and secondly, as a raging and fatal epidemic, not confined to its original seat, although exhibiting itself there in its most intense forms. It is the epidemic variety of this fatal malady that has engrossed so much attention from the earliest times down to the present; and we shall therefore briefly pass in review some of the principal circumstances which attend its origin, progress, and termination.

It has been observed that nearly all plagues have been preceded by certain natural signs, and by a greater mortality from malignant diseases generally than at other times. Among these precursory signals, great and sudden atmospheric vicissitudes have been noted. Livy (v. 13) attributes the origin of a pestilence to this cause. "The year was remarkable," he observes, "for a cold and snowy winter, so that the roads were impassable and the Tiber completely frozen. This deplorable winter, whether it was from the unseasonable state of the air, which suddenly changed to an opposite state, or from some other cause, was succeeded by intense heat, pestilential and destructive to all kinds of animals." But in the great plague of Athens, of which Thucydides has given so minute a description (ii. 48, &c.), he observes that the year of the plague was particularly free from all other diseases; and he mentions nothing unusual as having occurred in preceding years. The city however was then greatly over-crowded with inhabitants, a great part of the population having taken refuge within the walls of Athens (ii. 16), in consequence of the war. [PERICLES, BIOG. DIV.] Russell informs us that the winter of 1756–7, which preceded the petechial fever of 1758 at Aleppo, and the plague of 1759-60-1-2 in different parts of Syria, was excessively severe. Olive-trees which had withstood the weather for fifty years were killed. In the following summer a dearth ensued from the failure of the crops, and so severe a famine, that parents devoured their own children, and the poor from the mountains offered their wives for sale in the markets to buy food. The connection between famine and pestilence has been noticed in all ages of the world. An enormous increase of insects has frequently been observed to precede a pestilence. We are informed by Short, that in 1612 Constantinople was infested with crowds of grasshoppers of great size that devoured every green thing, and the next year (1613) the plague carried off 200,000 inhabitants of that city. In 1612, swarms of locusts laid waste the vegetable kingdom in Provence; and in 1613 the plague appeared in different parts of France. Locusts and pestilence are frequently mentioned together in the sacred writings; and we find that the plagues of Egypt exhibited a series of phenomena, rising in progression from corruption of the rivers and fountains, swarms of insects, murrain among cattle, thunder and thick darkness, and a tribe of inferior diseases, to that fatal pestilence which swept away the first-born of the Egyptians. In fine, dearth or unwholesome provisions, pestilence among cattle, great abundance of insects, absence or death of birds, blight and mildew, appear, with few exceptions, to have separately or conjointly preceded or attended all such calamities. Plague is usually preceded by other diseases which occasion great mortality. Lord Bacon has observed that "the lesser infections of small-pox, purple fever, agues, &c., in the preceding summer and hovering all winter, do portend a great pestilence the summer following; for putrefaction rises not to its height at once;" and Dr. Mead states, as a general fact, that fevers of extraordinary malignity are the usual forerunners of plague. Indeed nearly all the most remarkable plagues of the last two centuries have been preceded by malignant fevers. The increased number of deaths from this source will be seen by an examination of the London Bills of Mortality at the three last plague epochs in this country, an abstract from which we here present, showing the number of deaths from other diseases besides the plague, in 1625, 1636, and 1665, with that of the year before and after respectively:—

Years.	Common Diseases.	Plague.
1624	12,199	11
1625	18,848	35,417
1626	7,400	134
1635	10,651	. .
1636	12,959	10,400
1637	8,681	3,082
1664	18,291	6
1665	28,710	68,596
1666	10,840	1,998

The season of the year in which plague commits its greatest ravages differs in different countries. In Europe it has invariably raged most violently and fatally in the summer and autumnal months, especially in September. Thus, in the plague of London in 1665, the deaths from the plague were: in June, 590; in July, 4129; in August, 20,046; in September, 26,230; in October, 14,373; in November, 3449; and in December they were under 1000. In Egypt it commences in the autumn, and prevails till the beginning of June, and the vernal equinox is the period of the greatest fatality. Extremes of heat and cold generally check, and not unfrequently entirely arrest its progress. In tropical climates the disease is unknown, and in Egypt, according to Alpinus, to whatever degree pestilence may be raging, as soon as the sun enters Cancer it entirely ceases. The cold weather of northern climates has been observed to check the ravages of plague; and in these countries, when it has broken out in the autumn, its course has been arrested during the winter months. With respect to the progress and termination of plague, the disease appears to be subject to the same laws as regulate the course and termination of other epidemics: it is most fatal at its first outbreak, and becomes less virulent as it increases in extent. The increased mortality which occurs during the advance of plague, and which we have before shown to be at its height in the month of September, arises from the increased extension, and not from the greater malignancy of the disease. With its progress and decline there has usually been observed a progressive increase and decrease in the whole train of diseases, and those which had immediately preceded plague, on its decline reappeared. The former fact will be seen by a reference to the table we have given above.

The causes of plague have been referred by some to a vitiated atmosphere, engendered by epidemic and endemic causes, and wholly independent of contagion; while others have attributed it solely to the latter influence. The truth probably lies between these extremes, and we have little doubt, from an examination of the evidence on both sides of the question, that both these causes do occasionally operate in the propagation of plague. As the foundation of quarantine establishments rests entirely on the supposition of the contagious nature of plague, we shall examine how far this can be supported by a reference to facts. It is asserted by the contagionists that plague is transferred from individual to individual in all the ascertained modes in which diseases are thus communicated—by contact, by inoculation with the matter of buboes, through the atmosphere, and by fomites. According to them, its appearance in Western Europe has been always owing to imported contagion; and where strict isolation from all infected individuals and articles has been observed, there it has never appeared. It is admitted however by several, among whom may be mentioned the respected names of Sydenham, Russell, and Mead, that a peculiar atmospheric condition is essential to the spread of plague; yet they maintain that this is inadequate to its production without importation by fomites, or the arrival of a diseased person from an infected district. In support of this opinion, they refer to the histories of the different plagues that have visited Europe, and above all to that which ravaged Marseille in the year 1720. Its introduction into this city was traced to the arrival of three ships or lazarettos, which, by some means or other, for we learn not how, communicated the disease to a woman living in the Rue de l'Escale. This person being received into the Hotel Dieu, two of the nurses who assisted at her reception, and the matron who changed the linen, were taken ill the next day, and died after a few hours. In a short time it destroyed physicians, surgeons, apothecaries, confessors, and all the other officers and servants, with the whole of the poor in the hospital, including above 300 foundlings. The priests and monks who attended the infected suffered in the same manner as the medical assistants: and lastly, of 230 galley slaves, employed in going into the infected houses and burying the dead, 220 perished in the space of ten or twelve days. Dr. Bancroft justly observes that "it is fortunate for mankind that the communication of the contagion of the plague depends upon the co-operation of so many favourable circumstances, and particularly upon that of a suitable temperature, and of certain aptitudes and susceptibilities in the human subject; for without such requisites, or such obstacles to its propagation, the earth might have long since become desolate."

Those who contend for the non-contagiousness of plague, and therefore for the abolition of the quarantine laws, maintain that these laws, however strictly enforced, have not succeeded in shutting out the plague from pestilential districts: and that countries not possessing indigenous sources of pestilence are not visited with this disease, although unprotected by quarantine establishments. They likewise adduce numerous instances of persons in constant communication with plague patients, and even wearing their clothes, escaping the disease. Odessa has one of the best organised quarantine establishments in the world; yet not long ago the plague broke out in it, entered the town, destroyed a number of inhabitants, and ceased at a particular season. In 1835 the harem of the pasha of Egypt consisted of about 300 persons; but notwithstanding the severest cordon, the plague entered, and seven died within. The cordon was composed of 500 men, who were in constant contact with the town, where the disease was raging violently; of these only three died, so that the proportion of those who perished within to those without was nearly as 4 to 1. The plague of 1665, which ravaged most parts of this kingdom, never visited Oxford, although the terms were kept there, and the court and both houses of parliament were held there; a close correspondence too was maintained between this city and the metropolis, where it was raging. The Persians, although their country is every year surrounded by the plague, seldom suffer anything by it themselves. "The Turks and Moors," says Bruce, "immediately after St. John's day, expose in the market-places the clothes of the many thousands that have died of the plague during its late continuance; and though these consist of furs, cotton, silk, and woollen cloths, which are stuffs the most retentive of the infection, no accident happens to those who wear them." Clot Bey, who while at the head of the medical department in Egypt, treated thousands of cases, says, that removed from malaria or miasm, he has never known the plague to be communicated by contact. He has twice inoculated himself with the pus and blood of those affected with plague, but without producing the disease. Others, however, who have performed this operation on themselves, have contracted the disease and died.

This fully agrees with the evidence that was given before a select committee of the House of Commons, on the contagion of plague, in 1819. It appears from the Custom-house returns, that none of the expurgators of goods in Great Britain, at the quarantine establishments, have ever taken the plague. What then are we to regard as the cause of pestilence, and whence is it to be sought? Undoubtedly in the miasm of pestiferous soils; or of crowded, ill-ventilated, and filthy localities. When plague has at any time become epidemic, these are the spots in which it has first planted itself, and in which it has committed the greatest devastation. Notwithstanding the obviousness of this fact, it is a remarkable circumstance in connection with the history of plague, that no people in the world have been willing to acknowledge their own conntry to be the first or indigenous seat of pestilence. The doctrine that it is imported and not indigenous, is as prevalent in Turkey as it is in Egypt. The Egyptian Levantines insist that it has never been an Egyptian endemic, but has been imported by travellers or goods; while the Turks contend that it is from Egypt. In the eloquent language of Dr. Hancock, "Egypt disowns it; Ethiopia has no such progeny; Syria is too genial for its production; and Constantinople harbours it through neglect or sufferance. As to the north, how could the temperate climate of Britain generate a principle so terribly destructive?" Facts, however, are too numerous and weighty to allow us a moment's hesitation on this point. Wherever civilisation has advanced, there plague has receded, till it is now only to be found lurking among the swamps of Egypt or revelling in the filth of Constantinople. It is the spring, we have seen, that is so fatal to the Egyptians, about which time south winds prevail, loaded with putrid emanations from animal and vegetable substances in the lakes formed by the retiring waters of the Nile. In June, the wind is in the north, passing over the Mediterranean, and this is the most healthy and salubrious season. In Constantinople, the month of August is most fatal, and this is the season of the year when decomposition goes on with greatest rapidity. The exemption of the city of Oxford, in the plague of 1665, is a strong proof of the correctness of these opinions. The following words from Quincy are much to the purpose: "Dr. Plott observes, the reason why Oxford is now much more healthful than formerly, to be, the enlargement of the city, whereby the inhabitants, who are not proportionately increased, are not so close crowdud together; and the care of the magistrates in keeping the streets clear from filth. For 'formerly,' he says, 'they used to kill all manner of cattle within the walls, and suffer their dung and offals to lie in the streets. Moreover about those times, the Isis and Cherwell, through the carelessness of the townsmen, being filled with mud, and the common-sewers by such means stopped, did cause the ascent of malignant vapours whenever there happened to be a flood. But since that, by the care and at the charge of Richard Fox, bishop of Winchester, in the year 1517, those rivers were cleansed, and more trenches cut for the water's free passage, the town has continued in a very healthful condition, and in a particular manner so free from pestilential diseases, that the sickness in 1665, which raged in most parts of the kingdom, never visited any person there, although the terms were there kept, and the court and both houses of parliament did there reside.' " Now what was done in Oxford, as early as 1517, to remedy its unhealthiness, has since been done in all the principal cities of this country and on the Continent. Accordingly we find that the plague has not visited us since 1665. Holland, which has no system of quarantine, has experienced an exemption corresponding to that of our own country. Paris has not been attacked since 1668, and a century has elapsed since the plague of Marseille.

Treatment of Plague.—The preventive treatment of plague will be gathered from what we have said respecting the causes of this disease, and the most effectual barriers that can be opposed to its future introduction into Europe, are, to adopt again the language of Dr. Hancock, "the barrier of cleanliness in our towns and villages against filth and crowded habitations; the barrier of Christian charity towards our poor against famine and distress; the barrier of peace against the desolating evils of war; and the barrier of industry against the vice of sloth." With regard to remedial measures, it appears little can be done towards arresting the progress of plague after it has once declared itself in an individual. Our efforts therefore are limited to removing the patient from those sources of miasm which give origin to his disease, and in placing him in those conditions which are most favourable for his recovery. Free exposure to fresh air, supporting the strength, and regulating the secretions, are the only means which promise much chance of success. When this plan is adopted, we have the authority of our latest writers on this subject for declaring that the mortality of the disease may be considerably diminished. Thirty per cent. only, of those attacked, die under this mode of treatment; while in the lazaretto at Alexandria, 90 per cent. died in 1833, and 77 in 1836. With respect to the management of buboes and carbuncles, they must be treated in the way which is found efficacious in their removal when uncomplicated with plague, and if by these means we are unable to effect their dispersion, suppuration may be promoted by the employment of emollient cataplasms or any other mild stimulant.

In the following chronological table of some of the principal plagues upon record, we have purposely omitted the mention of many which, although described under that name, are obviously a different disease; even among those we have selected, the vagueness with which the symptoms of some are described, leave us in doubt whether the disease was the same as that which at present goes under the name of plague:—

B.C.
1491. The plague of Egypt. (Exodus, xii.)
1490. " in the Wilderness. (Numbers, xi.)
1250. " of Ægina. (Ovid's 'Metam.,' lib. vii. 523.)
1190. " in the Grecian camp at the siege of Troy. (Homer's 'Iliad,' book. i.)
1141. " among the Philistines. (1 Sam., v. vi.)
1017. " in Canaan. (2 Sam., xxiv.)
738. " of Rome. (Plutarch's 'Life of Romulus.')
464. " " (Livy, iii. 6; Dion. Halicar., lib. x.)
454. " " (Livy, iii. 32.)
437. " " (Livy, iv. 21, 25.)
430. " of Athens. (Thucydides, ii. 48, &c.)
404. " of Carthage. (Justin, xix. 2; Diod. Sic. xiii., xiv.)
366. " of Rome. (Livy, vii. 1; Short, 'On Air.')
296. " " (Livy, x. 31, &c.; Orosius, iii. 21.)
213. In the Carthaginian and Roman armies before Syracuse. (Livy, xxv. 26.)
182–177. Rome and all Italy. (Livy, xli. 21.)
126. Numidia and Carthage. (Livy, 'Epit.,' 60; Orosius, lib. 5.)
A.D.
68. Rome. (Tacitus, 'Annals,' xv. 47; xvi. 13; Orosius, lib. vii.; 'Univers. Hist.,' vol. xiv., 139.)
167, and few following years. Rome, and a large part of the known world. (Am. Marcellinus, lib. xxiii.; Echard's 'Rom. Hist.,' vol. ii., 315, &c.)
187. Rome and Italy. (Herodian, lib. i.)
252–270. Rome and a large portion of the globe. (Zonaras, lib. xii.; Gibbon, vol. i. 10.)
407. Most of Europe, Asia, and Africa. (Nicephorus, xiii. 6, 36; Magdeburg, cent. v. 13.)
542–590. A plague raging with intermissions, in most parts of the world. (Niceph., xvii. 18; 'Eccles. Hist.,' lib. iv. 29.)
1345–1350. Europe, and most parts of the world. (Boccaccio 'Decameron,' 'Prima Giornata;' Muratori, iii. 588, &c.; Villari; Short 'On Air,' vol. i., 165; 'Univ. Hist.' vol. xxxii.)
1562 and 1563, London and most of the principal cities of Europe. (Short, vol. i.; Thuanus.)
1575 and 1576. Italy and most parts of Europe. (Thuanus, lib. lxii.; Short, vol. i.; Mercurialis, 'On the Plague of Venice.')
1580 and 1581. Grand Cairo and different parts of France. (Thuanus.)
1600 and 1603. London and various parts of Europe. (Maitland's 'Hist. of London;' Mignot, 'Hist. of the Turkish Empire,' p. 256.)
1611 and 1613. Constantinople, France. (Riverius, lib. xvii.; Short, vol. i.; Mignot.)
1625. London and various parts of Europe. (Short.)
1635 and 1636. London, Nimeguen, and several other places in Europe. (Diemerbroeck, 'Tractatus de Peste.')
1655 and 1656. Most of Europe. Naples suffered very severely, three-fourths of its inhabitants having perished. 'Univ. Hist.,' vol. xxviii., 318.
1663–65. London and most parts of England and Holland. (Sydenham; 'City Remembrancer;' Hodge's 'Loimologia.')
1702–11. North of Europe. (Described, especially as it appeared in Danzig, by Dr. Gottwald; and 'Univ. Hist.,' vol. xxxv.)
1720. Of Marseille. (Chicoyneau's 'Traité de la Peste;' Bertrand's 'Relation Hist. de la Peste de Marseilles.')
1743. Aleppo. (Its 'Natural History,' by Dr. Alex. Russell.)
1751. Constantinople. (Chenier's 'Morocco,' vol. ii., 275.)
1760–62. Aleppo, Jerusalem, and Damascus. ('A Treatise of the Plague. &c.,' by Dr. Patrick Russell.)
1770 and 1771. Constantinople, Poland, and Russia. (Described, especially as it appeared in Moscow, by Mertens; and 'Ann. Regist.,' 1772, p. 155.)
1783–85. Egypt, Dalmatia, Constantinople, &c. (Volney's 'Travels, vol. i., 192; 'Courant,' October 28, 1783, and October 27, 1785.)
1799. In the French army in Egypt. (Sotira, 'Mémoire sur la Peste observée en Egypte pendant la Sejour de l'Armée d'Orient dans cette Contrée;' Baron Larrey, 'Description d'Egypte, &c.')

For further accounts of the plague, as it has appeared more recently, see Tully's 'Hist. of the Plague in the Islands of Malta, Gozo, Corfu, Cephalonia, &c.,' 1821: also Dr. Bowring's 'Observations on the Oriental Plague and on Quarantine, &c.,' 1838; and Dr. Andrew White, 'On Plague and Quarantine,' 1846.

Pestilential, Epidemic, or Asiatic Cholera is a disease not less fatal than that described in the preceding article; and in its endemic origin, its occcasional epidemic eruptions, its selection of victims, and the localities which it ravages, it bears a striking resemblance to plague. Its essential character is, however, perfectly distinct, as will be seen by the following account of the symptoms of cholera. The disease has two well-marked stages: the cold or choleraic, called also the stage of collapse; and the hot or febrile stage, or that in which reaction takes place. The first is generally preceded by certain premonitory symptoms, among the most prominent of which is diarrhœa, accompanied usually with languor and some degree of nausea; the dejections are fæcal and bilious, and often very copious. The commencement of the purging may precede the accession of the febrile stage for several days, or only a few hours may elapse. It is important not to think lightly of this disorder during the prevalence of epidemic cholera, for many a life might have been preserved if timely warning had been taken, and appropriate treatment adopted for removing it, before the accession of the symptoms about to be described.

Symptoms of the cold stage.—The time of its invasion is, in the majority of instances, from two to four o'clock in the morning. The patient is attacked with uneasiness of the stomach, to which speedily succeed vomiting and purging of a watery, colourless, and inodorous fluid, similar to barley-water, or more frequently *to rice-water;* sometimes it is like milk, and occasionally yellowish; but the 'conjee-stools,' as they are termed, which consist of albuminous flakes floating in serum, or discharges of pure serum, are of the most frequent occurrence. These discharges are attended with severe cramps in the extremities, especially in the calves of the legs, and are succeeded by exhaustion, giddiness, and sinking of the pulse; the pulse is small, weak, and accelerated; and after a certain interval becomes imperceptible. The skin is cold from the commencement; and as the disease advances, it becomes gradually colder, and is covered either with a profuse sweat or a clammy moisture. The temperature of the whole body is lower than natural. The features are shrunk and anxious: there is restlessness and agitation, with great thirst, heartburn, and hurried respiration. Notwithstanding the coldness of the body externally, the patient complains of heat, and throws off his bed-clothes. As the cold increases, the skin frequently becomes blue; the eyes, which are dull and suffused, seem drawn into and fixed at the bottom of their sockets; the tongue is cold but moist; the voice is feeble, hollow, hoarse, and interrupted; but the mental functions remain undisturbed to the last. At this advanced period the collapse is complete, the respiration very slow, and the patient, who suffers little or no pain, presents the appearance of a person who has been dead for some time. The urine is usually suppressed throughout the whole of this stage; but the dejections, becoming thinner and thinner, continue to the last. Some patients, although blue, cold, and pulseless, have sufficient strength to go about; many, however, die of exhaustion before all these symptoms have declared themselves. In the majority of cases the spasmodic symptoms are first observed, and afterwards the collapse; the former are characterised by pain, evacuations, and moans; the second, by the suppression of voice, urine, and heat. If, however, the patient get over the cold stage, that of reaction commences. The coldness and blueness gradually disappear; the pulse returns, increasing in force and frequency; to the pale or blue cheek succeeds the flush; the eye brightens; the tongue, which was of a dirty white, becomes cleaner and dry; vomitings are less frequent, but diarrhœa continues; and there is some tenderness of the abdomen, with thirst, great disgust of food, and intense headache. The urine, however, is secreted; and if all goes on well, at the end of two or three days the features assume their usual expression; the stools are less frequent and more natural; the strength and appetite begin to return; the pulse resumes its ordinary character; and the patient is convalescent. Several varieties occur in the duration and intensity of cholera, and complications are sometimes produced of a character not less fatal than the disease itself. We are informed by M. Dalmas, that soldiers attacked in full march will retire from the ranks, lay down their arms by the roadside, and expire in two hours. During the prevalence of the last epidemic in India, several instances were heard of at Houbley and other places in that country, of natives being struck with the disease while walking in the open air; they fell down, retched a little, complained of vertigo, deafness, and blindness, and expired in a few minutes. This rapidly fatal form of cholera has not been observed in this country. The most severe cases that we have met with generally lasted five or six hours; but the average duration of the fatal cases, when they did not terminate in consecutive fever, was from twelve to fourteen hours. When reaction was established, and fever supervened, the duration of fatal cases was from four to ten days. As a general rule to guide us in forming a prognosis, it may be stated that the more complete is the collapse, the greater is the danger; and if the patient survive it, the more violent and malignant is the subsequent fever. The cases in which spasms and vomiting are most violent are by no means the most dangerous.

Morbid Anatomy of Cholera.—Dissection presents us with nothing satisfactory by which we can judge of the nature of the disease. There is general venous congestion of all the important organs in the body; but it is rare that any traces of inflammation are discovered. The gall-bladder is mostly distended with bile, and its ducts are constricted. In the stomach and intestines is found either a transparent or a turbid serous fluid, mixed with a white opaque substance in the form of flakes, and similar in all respects to the matters ejected during life. The mucous membrane lining the intestinal canal is most frequently of a pale white colour, and somewhat more soft and pulpy than in its natural condition; but occasionally some degree of vascularity is observed. The urinary bladder is empty and contracted. With respect to the blood, it is found to be more viscid, and darker coloured than natural, which arises from a deficiency of its saline and watery components, and a relative increase of its solid constituents. In 1000 parts of serum, Dr. O'Shaughnessy found 133 of albumen, whereas healthy serum contains only 78 parts. On comparing the blood with the matter found in the intestines, it is manifest that the latter contains all the ingredients of the blood, except the red globules; and that the aqueous and saline parts pass out of the circulation more rapidly than the albuminous. This state of the blood explains the congestion more especially in the lungs, and accounts for the derangement of the functions of the respiratory system.

History and Statistics of Cholera.—There appears to be little doubt that pestilential cholera has from time immemorial visited the various populations of the world. It was described by Sydenham in the 17th century, and various outbreaks are recorded during the 18th century. It however excited the greatest attention in Europe during the second quarter of the present century. That this form of cholera is more or less indigenous in Europe is the opinion of most medical writers at the present day. The circumstances which cause the sporadic form to assume a contagious and epidemic character are not well understood. During the present century Europe has sustained three outbreaks of this disease. The first in 1828-29, 30 and 31; the second in 1847-48, and 49; the third in 1852-3, and 4. The history of the first outbreak is as follows:—It originated in the district of Nuddeah and in some other parts of the delta of the Ganges, about the end of May or the beginning of June, 1817. During that year it did not extend beyond the territory of Lower Bengal; but in 1818 and the early part of 1819 it diffused itself throughout the extreme length and breadth of the Indian peninsula, yet leaving untouched many districts placed between its lines of movement. Its progress along the lines selected was wonderfully uniform, being, for some successive months, at the rate of about one degree in a month. As early as 1818, it extended itself beyond the boundaries of Hindustan into the Birmese empire and other parts of Eastern Asia, and making gradual progress through these countries, reached China in 1820, and in the following year visited the numerous and populous islands of the Indian Archipelago. The Isle of France suffered its invasion in 1819, and some cases occurred in the same year at one point in Bourbon. In 1821 it extended along the shores of the Persian Gulf, and, during this and the following year, spread through parts of Arabia, Persia, and Syria, and closely threatened Europe. It appeared in the Russian territories in 1823, at Teflis, Orenburg, and Astrakan; but its farther northern and western progress was stopped for a time. It however reappeared in Orenburg in 1828, and again in 1829, and in 1830 advanced through the southern provinces of the Russian empire, till it reached Moscow on the 28th of September of that year, and Petersburg the year following. Warsaw was attacked in March, 1831; Danzig in May; Berlin, in August; Hamburg and Sunderland in October; and London and Paris in 1832. At the end of 1833 it had reached Mexico and several other parts of America. We see that the course of the epidemic was principally from east to west, and it was observed that prior to its appearance in many countries, and during its continuance, easterly winds were uncommonly prevalent; but most accurate and extensive meteorological observations, made daily during the continuance of the disease, prove that neither variations of temperature, fluctuations of the barometer, change of wind, nor the prevalence nor absence of moisture, affect in the slightest degree its duration or intensity. Bowel complaints appear to have preceded the cholera in most places, and to have continued for some months after its cessation. In many localities the disease existed only for a few weeks, while in others it lingered for several months. In the first case, the mortality was invariably high; in the last, the malignancy of the disease generally diminished as its stay was prolonged. Into whatever country or town the disease advanced, its first and most deadly fury was expended upon the poorest and most miserable of the population, and upon those who inhabited crowded districts, or low humid localities bordering on a port or river. Among this class of individuals whole families were sometimes cut off by it; indeed it is a peculiar feature of epidemic cholera that its ravages are confined almost exclusively to the poor. When the disease has appeared in a family occupying a station in life above the labouring class, we have the authority of Dr. Brown for declaring that in every case it has been confined to the individual first attacked, and has not in any instance spread to the other members of the family. The mortality from this disease is very great; but it varies somewhat in different countries and at different stages of its epidemic career. During its early prevalence in India, in 1817 and 1818, we learn, from the 'Report to the Medical Board at Bombay,' that there is reason to believe that of 1294 cases which received no medical assistance, every individual perished; and it is added, that it is not ascertained that any person has recovered to whom medicine had not been administered. This appalling statement however is without parallel, and it is gratifying to know that where the premonitory symptoms have been combated by early and judicious treatment, the mortality has always been diminished. This is strikingly exemplified by the statistical records kept at our different military stations in various parts of the world. In all situations and under all modes of treatment, about one in two died of the cases in civil, and one in three of those in the military hospitals; a result doubtless to be attributed to the strict surveillance exercised over the troops, by which nearly one-half of the cases among them were noticed in the premonitory stage, and consequently could be treated with a greater prospect of success than those in the civil hospitals, where the great majority of the patients were far advanced in the disease before they applied for medical aid. Of the severe cases however the mortality is probably nearly the same in all, being about 60 per cent. One of the most extraordinary features of this epidemic, observes Major Tulloch, is that the proportion of deaths to the number attacked has been very nearly alike in all the military commands of which the medical records have been investigated: for instance—In the United Kingdom, the deaths were 1 in 3¼; in Gibraltar, 1 in 3⅙; in Nova Scotia, 1 in 3¼; in Canada, 1 in 3; in Honduras, 1 in 3; in the Mauritius, 1 in 8⅓. The Mauritius appears to be the only exception to this; so that either the epidemic was less severe in its character, or the remedies employed were more successful.

The influence of age on the mortality by this disease among the troops of the line serving in Canada is exemplified in the following table:—

Age.	Ratio of Deaths at each Age, per 1000 of strength by Epidemic Cholera.
Under 18	—
18 to 25	15·5
25 to 33	28·
33 to 40	36·6
40 to 50	70·6

It appears from the authority to which we are indebted for the foregoing table, that females were attacked in very nearly the same proportion as males, but that the cases proved more generally fatal. Children were in a great measure exempt, though, when attacked, they rapidly sunk under it. The greater mortality of the disease in females has also been observed in this country. Dr. Ogden informs us that of 145 fatal cases of cholera at Sunderland, 63 were males and 82 females. The information which we possess on the relative mortality of the disease in the different races of mankind is rather meagre. The native Indians of North America suffered from it in an equal degree with the white population; and the same was observed with regard to the Sepoys in our Indian army. In the Mauritius, whose population in 1831 was 90,000, of which 25,000 were whites and the rest coloured, the total number of deaths recorded in the civil and military hospitals was 1327. Of these 168 were whites, 162 coloured, and 997 blacks, principally negroes, who seemed peculiarly subject to the disease. At this date, more than 2000 out of 4300 slaves belonging to government were cut off by it, and of those belonging to the planters nearly as many.

The disease as it appeared in Europe in the two last outbreaks presented no new features. There was the same great mortality at the onset. It travelled from city to city in the same manner and gradually disappeared. It broke out in England in 1848, and was present in London in 1849. It subsided and again appeared in 1853, and in London in 1854. Since that time it has gradually subsided, and no great epidemic has occurred in Europe since.

The number of persons attacked in a community by cholera has varied very considerably. In no instance has a whole population been attacked during an outbreak. In the marching corps of our army the number attacked has been from 17 to 330 for 1000 men. Moreau de Jonnès has given the following estimate for the numbers attacked in the countries of Europe.

France	1 in 300	Belgium	1 in 120
Russia	1 in 20	Great Britain and Ireland	1 in 131
Austria	1 in 30	Holland	1 in 144
Poland	1 in 32	Germany	1 in 700
Prussia	1 in 100		

Causes of Cholera.—That the whole series of phenomena results from the action of a morbific poison on the body, there can be no doubt; that this morbific matter is indigenous to some countries, and apparently has its origin in certain peculiar conditions of the soil, is supposed to be true from the effects which we find to be produced upon animal bodies living in these districts. But why the miasm arising from the overflow of the Nile should produce plague; that of the Ganges, cholera; that of the parts situated in the tropics, yellow fever; or our own marshes, simple intermittent—we are entirely ignorant; nor can we, in the present state of our knowledge, at all account for the epidemic spread of some of these endemic diseases.

Notwithstanding the extensive knowledge acquired from the recent outbreaks of the disease in Europe, no consistent theory of its cause has been proposed. Whilst its history would seem to point out the production of a poison in the interior of Asia, which was gradually conveyed to other parts of the world, there is not wanting evidence to show that similar epidemics have occurred without any trace of such origin. It seems not impossible that, under certain meteorological or other external circumstances, the ordinary diarrhœa or cholera of a district may acquire a contagious character; that is, the body may generate a poisonous matter, which, being carried into an otherwise healthy system, may engender the disease. Such a contagious character is occasionally assumed by diseases which do not ordinarily present this character, as erysipelas and dysentery. The following summary of the various theories which have been entertained to account for the spread of cholera is given by Dr. Aitken, in his 'Science and Practice of Medicine':—

1. “That the disease spreads by an atmospheric influence, or epidemic constitution by a succession of local outbreaks, and that the particular localities affected are determined by certain 'localising conditions,' which are, first, all those well-known circumstances which render places insalubrious; and second, a susceptibility to the disease in the inhabitants of such places, produced by the habitual respiration of an impure atmosphere.”

2. “That the cause of cholera is a morbific matter, which undergoes increase only within the human body, and is propagated by means of emanations from the bodies of the sick; in other words, simply by contagion.”

3. “It is supposed that the poison of cholera is swallowed, and acts directly on the mucous membrane of the intestines, and is at the same time reproduced in the alimentary canal, and passes out much increased with the discharges; and that these discharges afterwards, in various ways, but chiefly by becoming mixed with the drinking waters in rivers and wells, reach the alimentary canals of other persons, and produce the like disease in them.”

4. “Assuming that the cause of cholera is a morbific matter, or poison, it is supposed that it is reproduced only in the air, and within the bodies of those whom it affects, and that its diffusion is due to the agency of the atmosphere.”

5. “It is supposed that the cholera poison is increased by a species of fermentation, or other mode of reproduction, in impure, damp, and stagnant air; and it is maintained that it nevertheless is distributed and diffused by means of human intercourse, it being carried in ships and other vehicles, and even in the clothes, especially in the foul clothes of vagrants, and the accumulated baggage of armies.”

6. “It is assumed that the material causes of the disease may be increased and propagated in and by impure air, as well as in and by the human body.”

Those who deny the existence of any specific poison, give the greatest prominence to meteorological conditions and the external circumstances that induce a predisposition to the disease. Those who admit the existence of a poison, cannot deny the controlling influences exercised by these agencies.

Although there is no evidence to connect all attacks of cholera with a particular state of the atmosphere, there is much evidence to show that cholera occurs, as a rule, with an increased temperature, and that, *cæteris paribus*, the higher the temperature the more virulent is the disease. During the first outbreak of cholera in Great Britain, the temperature of the preceding year had not only been unusually high, but the atmosphere, both inland and sea, was unusually stagnant, close, and hot. This state of the atmosphere was observed both in the second and third outbreaks. Mr. Glashier observes, that there was a misty condition of the atmosphere, and that the readings of the barometer were remarkably high; while in the two last a total absence of ozone was observed. In other parts of the world similar phenomena have been observed. Such states of the atmosphere are attended with a marked tendency to putrefactive change in organic substances, and the consequent diffusion of their products in the air.

But whilst these general conditions of the atmosphere have existed during an outbreak of cholera, the occurrence and spread of the disease has been determined by a variety of circumstances, which have acted as predisposing causes in individuals. Amongst the most active of these may be mentioned impure water, lowness of site of dwelling, and the emanations of animal and vegetable refuse.

The action of impure water is well illustrated in the history of the two epidemics occurring in London in 1849 and 1854. The district of Lambeth, in 1849, was supplied with water by two companies, the Lambeth and Vauxhall water companies, both deriving their water from the Thames at Battersea. In this year, the population which was supplied by those companies suffered equally from cholera. But when the cholera revisited London in 1854, the Lambeth company was obtaining a new supply of water higher up the river, at Thames Ditton, beyond the tidal action of the river. The consequence of this improved supply was very remarkable in its action on the predisposition of the inhabitants to take cholera; for although the Lambeth company supplied houses in the same streets, and over precisely the same character of population, as the Vauxhall company, it was found that the deaths from cholera in the latter population were as 7 to 1 of the former. In all respects the supply of water was the same, but that in the one case the company supplied a water more highly charged with organic impurities than in the other. A still more striking case, illustrative of the influence of impure water in the production of cholera, occurred in the district of Broad Street, Golden Square, St. James's, Westminster, in 1854. In the course of five or six days, from the 30th of August, not less than five hundred persons died of cholera out of a population of not more than four or five thousand. After a rigorous investigation, it was ascertained that the majority of those persons had partaken of water from the pump in Broad Street, which on examination was found to communicate with a cesspool in an adjoining house. ('Report on the Cholera Outbreak in the Parish of St. James, Westminster, in 1854.') Numerous other examples are recorded of the connection of cholera with the drinking of impure water.

With regard to the locality of houses, Dr. Farr has shown, for London, that nothing has so constant a relation to the fatality of cholera as the elevation of site. He has shown that, just as we ascend from the banks of the river Thames to the higher localities around it, the mortality of cholera diminished. This is undoubtedly connected with the fact that the greatest accumulation of organic refuse occurs on the banks of rivers into which the sewage of a city is poured.

The effluvia which pass off from decomposing animal and vegetable matter seem to have a great influence in predisposing the system to the reception of the choleraic poison. It is well known that the atmosphere of dissecting rooms, and places where animal bodies are decomposing, produce on those exposed to it a tendency to diarrhœa. This is also the case with the excretions of animals, when they are allowed to undergo putrefactive changes. Hence it has been found that diarrhœa and cholera prevail especially in those houses and streets which are undrained, and where human refuse is allowed to accumulate in cesspools. The instances recorded of the breaking out of cholera in the neighbourhood of foul drains, or of recently opened cesspools, are very numerous and conclusive on this point. In many towns in England, where the inhabitants suffered severely from a first attack, they obtained during the subsequent visitations an entire immunity, by the improvement of the drainage and the substitution of water-closets for privies and cesspools.

Independently of external causes, there are certain facts connected with the individual that act as predisposing causes. Thus, with regard to *age* and *sex*, Dr. Farr found that males suffered more than females at the ages under 25 years, but between 25 and 45 the females suffered more than the males. During the prevalence of cholera in Paris in 1832, it was found that the mortality was least from 6 years to 20, greater from 30 to 40, and greatest of all above 40 years. *Habits of life* exercise a great influence in predisposing to cholera, and there is no question that, in all countries, the lower classes have suffered more than the upper classes. This was observed in India, where, in all the large cities, the natives suffered more than the European population; where the Brahmin merchant suffered less than the ryot, and the ryot less than the pariah. In the cities of Europe, everywhere the poor and ill-fed suffered most. As a rule, Mohammedan nations have suffered more than European, and the Hindoos more than Mohammedans. As indicating the influence of low diet, it has been stated that the Mohammedans suffered much more during their rigid fasts. The excessive *use of alcoholic liquors* has everywhere been observed as a predisposing cause to cholera, whilst entire abstinence from them seems also to have invited attacks. Exhaustion from *fatigue* also invites the action of the poison. This has been remarkably exemplified in the movements of the army. When troops have been marched a long distance, they have been immediately seized with cholera on reaching their destination, whilst soldiers who have remained in camp during the same time have experienced no attack at all.

Treatment of Cholera.—Premising, in a prophylactic point of view, the superiority of avoiding all the predisposing causes of cholera to the absurd practice of swallowing specifics against the disease, our treatment must be regulated according to the state in which we find the patient. The diarrhœa may be treated by a dose of calomel and opium combined with some aromatic, at once, and small doses of opium should be continued every hour till the diarrhœa is restrained. Bleeding has been recommended at this period of the disorder, but all experience shows this to be a dangerous practice. If the patient is already in a state of collapse, the various modes of treatment which have been adopted prove how little is to be effected when the disease has advanced to this stage. Major Tulloch informs us that the principal remedy of the American aborigines consisted in merely swallowing large quantities of charcoal mixed with lard; yet very nearly the same proportion recovered as among the white inhabitants of the towns who had the advantage of the best medical science. In this country, blood-letting, cold affusion, hot-baths, emetics, purges, astringents, sedatives, and stimulants of the most powerful kind, have been successively tried with very doubtful advantage. The plan however which has excited most attention is that by salines. Medical men, guided by chemical analysis, conceived the project of supplying by artificial means the serum which was found wanting in the blood. With this view lavements and potions of an alkaline solution, resembling serum in composition, were administered; but not being able by this means to arrest the vomiting, it was recommended and put into practice by Dr. Latta of Leith to inject the same fluid into the veins. This was first done by means of one of Reid's syringes, the temperature of the solution being kept at from 108° to 110° Fahr. Of 74 bad cases treated in this method, 22 recovered, and in one case only did any unfavourable symptoms occur, and this was from phlebitis, or inflammation of the veins. As much as 33 lbs. of this alkaline solution have been injected in the space of 52 hours, and with a successful result. Some practitioners have even exceeded in amount this quantity. The composition of the saline injection employed by Dr. Latta consisted of two drachms of common salt and two scruples of carbonate of soda dissolved in sixty ounces of water; but this formula has been slightly varied in different cases. The immediate effects observed on injecting this fluid into the veins are, an increase of the temperature and respiration, a reappearance of the pulse, if before imperceptible, or it becomes fuller, stronger, and slower, when it was before small, frequent, and feeble. The collapsed appearance of the countenance gradually vanishes; it becomes fuller and more natural; the eyes brighten, the thirst diminishes, and the patient expresses himself in terms of gratitude or satisfaction at the wonderful change wrought in his feelings. But this change is evanescent; the purging continues, and the patient is shortly reduced to the same hopeless state in which he was previous to the adoption of this treatment.

The failure of all heroic methods of treatment has induced the trial of almost all possible forms of treatment. All the metals have been given, as well as the non-metallic agents, the vegetable alkaloids, and mineral acids. Emetics, purgatives, diuretics, sudorifics, all have been tried, and although many of these remedies have been vaunted as cures, the terrible logic of statistical calculation has demonstrated that no one system can claim to be more successful than another. At the commencement of the epidemic all die alike, as the more predisposed are cut down, a larger number recover, and it is at this period the medical practitioner begins to attribute the recoveries to the success of his treatment. The London College of Physicians obtained the returns of the treatment of several thousand cases, and came to no conclusion as to any particular system. It may, however, be remarked that whatever remedy was given it was accompanied with some of the preparations of opium, and contrasting those plans of treatment which contained opium as an element, with those in which this remedy was omitted, it was found that the former were the more successful. Amidst then the vast experience of remedies in this deadly malady we have only this fact presented with certainty that opium alone in one form or another offers some chance of relief.

PETALISM. [Ostracism.]

PETARD. [Artillery.]

PETECHIÆ are small spots of a dark red colour produced by the effusion of drops of blood in the skin just beneath the cuticle. At first sight they look very like flea-bites, but they do not disappear when they are pressed with the finger. They usually indicate an altered state of the blood, and are often symptoms of very serious diseases, as in typhus fever (some varieties of which have hence been called petechial fever), scurvy, purpura, &c. They commonly appear also in very severe cases of small pox, measles, and scarlet fever, and are amongst the worst symptoms by which those diseases are marked.

PETECHIAL FEVER. [Petechiæ.]

PETER-PENCE, a tax anciently levied throughout England, according to some authorities, of a penny upon each house; according to others of a penny upon every house which contained twenty pennyworth of any kind of goods, and paid to the pope. This payment, in ancient times, passed under various denominations: Rome-fee, Rome-penning, and Rome-scot were the Saxon names; Denarii S. Petri and Census S. Petri, in Latin. The earliest payment of it is attributed by some to Ina, king of the West Saxons, A.D. 720; by others to Offa, king of Mercia, A.D. 790. At one period of his reign, Edward III. discontinued this payment, but it was revived by Richard II. It finally ceased at the Reformation.

(Du Cange's *Glossary; Leg. Edw. Conf. & Will. Conq.*)

PETER'S, ST. [Rome, in Geog. Div.]

PETININE. Synonymous with *butylamine.* [Organic Bases.]

PETIT-SERJEANTY. [Serjeant.]

PETITION. A petition is an application in writing, addressed to the lord chancellor, in which the petitioner states certain facts as the ground on which he prays for the order and direction of the court. Petitions are either *cause* petitions or not. A cause petition is a petition in a matter of which the court has already possession by virtue of there being a suit concerning the matter of the petition; and the petitioner is generally either a party to such suit, or he derives a title to some interest in the subject-matter of the suit from a party to it. When there is no suit existing about the matter of the petition, it is called an *ex parte* petition.

Some cause petitions are called petitions of course, and relate to matters in the ordinary prosecution of a suit, and before a decree. Such petitions are granted upon application of the party petitioning; and they may be presented at any time, whether the courts are sitting or not.

Other petitions in a cause, which are not petitions of course, and may be called special petitions, have for their object to carry a decree into execution. Thus a party who has an interest in a fund in court, a legatee for instance who was a minor when the decree was made, may, when he is of age, apply by petition to have his share paid to him, because his right to it has been recognised by a decree or order of the court, or by a master's report which has been confirmed. The nature of the petitions in a cause will of course vary with the subject-matter of the suit.

Petitions, not in a cause, are of various kinds, and many of them are presented under the authority of particular acts of parliament. These also are called special petitions. Thus a petition may be presented for the appointment of guardians to infants, and for an allowance for their maintenance; for the purpose of procuring an order of court that infant trustees and mortgagees may execute conveyances; and for various other purposes. In matters of lunacy, the form of proceeding in the first instance is by petition, the prayer being for a commission to inquire into the state of mind of the alleged lunatic. [Lunacy.] In subsequent proceedings relating to the property of a person, when found lunatic by a jury, a petition is the regular and usual course of proceeding; and suits are not commenced or defended for the lunatic without the previous approval and direction of the court.

All special petitions must be presented to the court to which they are addressed, in order to be answered: until they are answered, the court is not fully possessed of the matter of the petition. The answer, which is written on the copy of the petition and signed by the judge, requires the attendance before him of all parties concerned in the matter of the petition at the hearing thereof. It is the business of the petitioning party to serve all proper parties with notice of this petition, and the answer to the petition becomes an order of the court, upon every person whom the petitioner chooses to serve with the petition, to attend at the hearing of it; and if such person be absent at the hearing, he will be bound by the order made on the petition. Service of the petition consists in delivering a true copy of the petition as answered to the clerk in court whose attendance the petitioner thinks necessary, or to the party himself. In some special cases, the petitioner is permitted, on special motion, supported by an affidavit that he is unable to serve the party personally, to leave the copy of the petition at the party's house with one of his family, and this will be considered good service. Special petitions frequently require to be supported by affidavits of the petitioner or some other person, or of both; and such affidavits may be filed at any time after the petition is answered. If a petitioner choose to serve a party with a petition, whose presence is considered by the court to be unnecessary, he must pay such party the cost of attending at the hearing of the petition.

A petition is heard in court by the counsel for the petitioner stating the substance and prayer of the petition, and by reading or briefly stating the contents of the affidavits filed in support of the petition, if any have been filed. If the prayer of the petition is opposed by any of the parties who have been served with it, they are heard by their counsel, and their affidavits also, if any have been filed, are read or briefly stated to the court. On hearing the matter of the petition and the affidavits on both sides, the court either dismisses the petition or makes such order as it thinks fit. The order when made is drawn up, passed, entered, served, and enforced like any other decree or order of the court.

PETITION OF RIGHT. Where the crown or a subject has a cause of action against a subject, the ordinary mode of putting that cause of action into a course of legal investigation is by the king's writ, requiring the party to appear in court to answer the complaint. Where the claim is against the crown itself, as this course cannot be pursued, the mode of proceeding provided by common law is to present a petition to the crown, praying for an inquiry and for the remedy to which the party conceives himself to be entitled. As by Magna Charta the king is not to delay right, he is bound, if the petition presents that which has the semblance of a legal or equitable claim, to indorse the petition with the words "let right be done;" which indorsement operates, in the case of a claim of a legal nature, as a warrant and command to the lord chancellor to issue a commission to inquire into the truth of the matters alleged in the petition. A commission accordingly issues to six or eight persons, who summon a jury, of whom not less than twelve or more than twenty-three are impannelled, and who, under the superintendence of the commissioners, hear the evidence which the petitioner, or, as he is called, the suppliant, has to adduce in support of his statement. If the jury negative the allegations contained in the petition, the commission is at an end; but the suppliant is at liberty to sue out a new commission or commissions till a jury return an inquisition in which the allegations are found to be true. The crown may, upon this return, insist that the facts alleged by the suppliant, and found by the inquisition, do not in point of law entitle the suppliant to the remedy which he claims. The question of law thus raised by demurrer to the inquisition is argued before the lord chancellor. The crown, however, notwithstanding the finding of the jury, may deny the truth of the facts, or, admitting them to be true, may allege other facts which show that the suppliant is not entitled to what he claims. To such facts the suppliant must reply. Any issue of fact joined between the suppliant and the crown is tried in the court of Queen's Bench, the lord chancellor not having the power to summon a jury. Final judgment is given for or against the suppliant according to the result of the argument upon the demurrer or of the trial of the issue.

If the suppliant in his petition pray that the investigation may take place in a particular court, and the royal indorsement on the petition directs that course to be pursued, the proceedings take place in the court indicated by the indorsement, instead of the Court of Chancery.

Before the abolition of the feudal tenures by the Commonwealth (confirmed after the Restoration, by 12 Car. II., c. 24), the rights of the crown and of the subject being often brought into collision, occasions for proceeding by petition of right were very frequent, and as this mode of proceeding was dilatory and expensive, two acts, passed in the reign of Edward III., enabled parties aggrieved in certain cases by legal proceedings of the crown, to enter their claim upon those proceedings, without being put to their petition of right, with its expensive commission to inquire. This new course was called a "traverse of office," where the subject denies the matters contained in the "office" or *ex parte* record constituting the king's title, and a "monstraunce de droit," where the facts upon which the king's title rests are admitted, but their effect is avoided by the allegation of other facts showing a better title in the claimant. In modern practice the petition of right is not resorted to, except in cases to which neither a traverse of office nor a monstraunce de droit applies, or after those remedies have failed.

The petition of right is supposed by Lord Coke and others to be so called because the investigation prayed for is demandable as of right, and not granted as a matter of grace or favour; but the Latin term "petitio justitiæ," shows that the words are used in the sense of a "petition *for right*."

The petition of right hitherto spoken of is the method of redress provided by the common law. The statute 23 & 24 Vict. c. 35, has provided a simpler mode of proceeding. It enables the suppliant to entitle his petition in any of the supreme courts of law or equity, at Westminster; and to leave the same with the home secretary for the fiat of the crown. When this fiat is obtained, the petition is served on the solicitor to the treasury, who must appear and answer it, in the name of the attorney-general; all the subsequent pleadings and proceedings, including the trial, being according to the ordinary practice of the court in which the suit is pending. The suppliant and the crown in proceedings under this statute may recover costs, which are neither paid nor received by the crown upon a petition of right at common law, so that the statutory proceeding must in due course supersede the other.

(*Blackst. Com.*,' Mr. Kerr's ed., vol. iii., ch. 17.)

PETITION OF RIGHT. In the first parliament of Charles I., which met in 1626, the commons refused to grant supplies until certain rights and privileges of the subject, which they alleged had been violated, should have been solemnly recognised by a legislative enactment. With this view they framed a petition to the king, in which, after reciting various statutes by which their rights and privileges were recognised, they pray the king "that no man be compelled to make or yield any gift, loan, benevolence, tax, or such-like charge, without common consent by act of paliament,—that none be called upon to make answer for refusal so to do,—that freemen be imprisoned or detained only by the law of the land, or by due process of law, and not by the king's special command, without any charge,—that persons be not compelled to receive soldiers and mariners into their houses against the laws and customs of the realm,—that commissions for proceeding by martial law be revoked: all which they pray as their rights and liberties according to the laws and statutes of the realm."

To this petition the king at first sent an evasive answer:—"The king willeth that right be done according to the laws and customs of the realm, and that the statutes be put in due execution, that his subjects may have no cause to complain of any wrongs or oppressions contrary to their just rights and liberties, to the preservation whereof he holds himself in conscience obliged as of his own prerogative." This answer being rejected as unsatisfactory, the king at last pronounced the formal words of unqualified assent, "Let right be done as it is desired." (1 Car. I., c. 1.) Notwithstanding this, however, the ministers of the crown caused the petition to be printed and circulated with the first insufficient answer.

PETROLIN. [Bitumen.]

PETROSELINUM. [Parsley.]

PEUCEDANIN. [Imperatorin.]

PEUCYL. *Terebilene.* A liquid resembling camphine, obtained by the action of lime upon the monohydrochlorate of turpentine.

PEUTINGERIAN TABLE is the name given to a map of the roads of the ancient Roman world, which is on parchment, and was found in a library at Speyer in the 15th century. It was bequeathed by the proprietor Conrad Celtes to his friend Conrad Peutinger, a learned man of Augsburg, who began to prepare a copy of it for publication, but died in 1547, before he could effect his purpose. Mark Velter however copied it on a scale less than one-half of its original size, and sent his copy to Ortelius, who forwarded it to Muretus, who published it in 1598. This reduced copy has been inserted in the Ptolemy of Bertius, in Horn's 'Orbis Delineatio,' and in Bergier's 'Histoire des grands Chemins de l'Empire Romain.' The original map remained at Augsburg, in the possession of Peutinger's descendants, till 1714, when it was purchased by a bookseller, and sold by him to Prince Eugene, who gave it to the imperial library of Vienna. An exact copy of it was made by F. C. Von Scheyb, at Vienna, with an introduction and index, and dedicated to the empress Maria Theresa; 'Tabula Itineraria Peutingeriana, quæ in Augusta Bibliotheca Vindobonensi nunc servatur, adcurate exscripta à Fr. Christoph. De Scheyb, cum Indice,' fol., Vienna. 1753. The map is 21 feet in length, and about one foot wide. The author, whoever he was, did not intend to draw a proper geographical map, with the relative positions of countries, but merely to collect all the great roads of the empire into a long narrow strip, marking the stations upon each, and the distances between the stations, for the information of travellers and chiefly of military and civil officers. The towns on the roads are marked by small houses; some, being worthy of particular notice, are designated by square buildings like barracks; and some more important towns and military stations, such as Aquileia, Ravenna, &c., are distinguished by walls and towers. Rome is distinguished by a circle with a crowned figure seated in the middle, and the port of Trajan is conspicuously sketched near the right bank of the Tiber, at the mouth of the river. Constantinople is marked by a circle and a figure, which however is not crowned. Antioch is the only other city which is also distinguished by a circle and a figure, in which last Mannert thinks that he recognises the Virgin Mary, which he believes to be an interpolation of some copyist of the middle ages, who had before him an older map of the time of the Pagan emperors. (Mannert's 'Introduction' to his new edition of Peutinger's Table, folio, Leipzig, 1824.) That the original map was drawn while the old religion of the empire was still dominant, seems proved by the heathen temples which are marked upon it, whilst there is no Christian name, with the exception of St. Peter's at Rome, which is probably also an interpolation of the copyist.

Several other particulars on the map seem to fix the date of its original construction to about the time of Alexander Severus, after the Persians had overthrown the Parthian dominion, A.D. 226. The Persian empire is marked in its full extent and written in large capitals, whilst Parthia is indicated by smaller characters as a province. Palmyra is marked as an important place, with roads leading to it through the desert, which would seem to refer to an epoch previous to its destruction by Aurelian. Edessa in Macedonia is marked under that name, whilst in the Antonine Itinerary it is called Diocletianopolis. This and other evidence collected by Mannert indicate at all events an epoch between the reign of Alexander Severus and the end of the 3rd century, making allowance for the interpolations of subsequent copyists.

The Peutingerian Table does not always agree with the Antonine Itinerary; several stations and towns which are in the one are not in the other; the distances between the stations marked on both sometimes disagree; besides which, in consequence of the form of the map, several roads which are distinct on the Itinerary are placed on the map consecutively, as if they all formed one line; whilst others, which are single roads on the Itinerary, are cut into two or three in the map. However the Itinerary is still of great use in explaining the map, and the two together are among the most valuable ancient works on geography which have come down to us.

The map extends to the right, or east, as far the mouths of the Ganges. Roads are traced through India to several emporia, or places of trade, on the coast. To the west the map ends abruptly on the borders of Spain, including farther north only the eastern part of Britain. It is evident, as Mannert maintains, that one leaf is wanting, and it has perhaps been lost.

PEW. The word pew seldom occurs in writers upon ecclesiastical law, who almost invariably use the expression "church seat."

Originally there were no pews in churches, and the only fixed seats were stone benches carried along the sides of the churches, of which examples still remain in Salisbury and other cathedrals, and in Romsey church, Hants, Portbury, Somersetshire, and many other of our old parish churches. But in the 14th, and still more generally in the 15th century, open seats or benches of wood, with carved ends, were fixed across the nave (but leaving a broad central passage), though the practice was still perhaps not universal. These, legally termed "church seats," were commonly called "pews," but pews in the modern sense of the word, namely, enclosed seats, did not come into use until about the period of the Reformation. Before that time no cases are to be found of claims to pews, although in the common-law books two or three claims are mentioned to seats in a church, or particular parts of a seat.

By the general law and of common right, all the pews in a parish church are the common property of the parish; they are for the use *in common* of the parishioners, who are all entitled to be seated orderly and conveniently so as best to provide for the accommodation of all. The right of appointing what persons shall sit in each seat belongs to the ordinary and the churchwardens, who are his officers to place the parishioners according to their rank and station. A parishioner has a right to a seat in the church without any payment for it; and if he has cause of complaint in this respect against the churchwardens, he may cite them in the ecclesiastical court to show cause why they have not seated him properly; and if there be persons occupying pews who are not inhabitants of the parish, they ought to be displaced in order to make room for him. This general right, however, of the churchwardens as the officers of the ordinary is subject to certain exceptions, for private rights to pews may be sustained upon the ground of a faculty, or of prescription, which presumes a faculty.

The right by faculty arises where the ordinary or his predecessor has granted a licence or faculty appropriating certain pews to individuals. Faculties have varied in their form: sometimes the appropriation has been to a person and his family "so long as they continue inhabitants of a certain house in the parish;" the more modern form is to a man and his family "so long as they continue inhabitants of the parish" generally. The first of these is perhaps the least exceptionable form.

Where a faculty exists, the ordinary cannot again interfere; but where a party claiming by faculty ceases to be a parishioner, his right is determined. There may be, however, a prescription for a person living out of the parish to have a pew in the *body* of the church.

With respect to seats in the chancel, the law has not been settled, and great inconvenience has been experienced from the doubts continued to be entertained. It is said that the churchwardens have no authority over pews in the chancel, and it has been said that the rector, whether spiritual or lay, has in the first instance at least a right to dispose of the seats; claims have also been set up on behalf of the vicar; and the extent of the ordinary's authority to remedy any undue arrangement with regard to such pews has been questioned.

With regard to aisles or isles (wings) in a church, the case is different. The whole isle, or particular seats in it, may be claimed as appurtenant to an ancient mansion or dwelling-house, for the use of the occupiers of which the aisle is presumed to have been originally built. In order to complete this exclusive right, it is necessary that it should have existed immemorially, and that the owners of the mansion in respect of which it is claimed should from time to time have borne the expense of repairing that which they claim as having been set up by their predecessors.

The purchasing or renting of pews in churches is contrary to ecclesiastical law, pew-rents, under the church-building acts, being exceptions to the general law; and rents taken in populous places being usually sanctioned by special acts of parliament. Pew-rents in private unconsecrated chapels do not fall under the same principle, such chapels being private property.

PEWTER. An alloy of tin and lead, intermediate in hardness between lead and Britannia metal. The best pewter consists of four parts of tin and one of lead.

PHALANX (φάλαγξ), a name given by the Greeks generally to the whole of the heavy-armed infantry in an army, but particularly to each of the grand divisions of that class of troops. The primary signification of phalanx is uncertain; a straight bar or rod of any material appears to have been so called, and the word may have been applied to a corps of troops, in line, from a fancied resemblance in the latter to such object. Ultimately, from their superior military efficiency, it became appropriated to the Spartan phalanx and the Macedonian phalanx.

The Greek troops are represented by Homer as disposed in masses consisting of many ranks, in order that they might resist, or give impetus to the shock of conflict; and the word *phalanges* is, in several parts of the Iliad, applied to the masses of the combatants, both Greeks and Trojans:

'Αμφὶ δ' ἄρ Αἴαντας δοιοὺς ἵσταντο φάλαγγες

('Il.,' xiii. 126; see also 'Il.,' iv. 332, vi. 83); and the close order of the Greeks previously to coming into action is described in 'Il.,' xiii. 130, and the succeeding lines.

A like disposition prevailed among the Egyptians in the earliest times of their monarchy, and of this fact some interesting vestiges are preserved in the sculptures on the walls of the temples at Ipsambul and of the palace at Luxor. At the former place an Egyptian army is represented as marching in separate divisions of chariots and foot soldiers drawn up in quadrangular bodies, in ranks, and in close order. Each man of the infantry is armed with cuirass and helmet, and carries a shield and a short javelin; and among the figures is that of Sesostris in full panoply, standing in a highly ornamented car. (Rosselini, 'I Monomenti dell' Egitto,' plates 87 to 103.) But, from the nature of the arms and the apparent discipline of the troops, it may be inferred that, at the epoch to which the monuments relate, the tactics of the Egyptians were in a very advanced state, and consequently that the order of battle there represented was in use among that people at a time much more remote than the age of Sesostris.

The ancient Jewish army, modelled probably on that of the people who had long held them in servitude, was divided into bodies of 1000 men each, which were again divided into companies of 100 men (2 Sam., c. 18); and it is plain, from other passages in the Scriptures, that these were further subdivided into sections. It consisted both of heavy and of light armed troops: the former wore helmets, coats of mail, and greaves, and in action they carried bucklers and used both spear and swords; the latter also carried shields and used bows or slings. The men who, from the different tribes, assembled at Hebron to confirm the election of David, are described as being armed with spear and shield, and their discipline is indicated by the expression—they could keep rank.

The troops in the army of Crœsus are said by Xenophon to have been drawn up in vast masses, the depth of the Lydians being thirty men, while that of the Egyptian auxiliaries was one hundred; and it is added that the whole army had the appearance of three great *phalanges*. ('Cyropædia,' lib. vii.) It is sufficiently evident therefore that the deep order of battle, with a regular arrangement of the men in rank and file, and some systematical division of the phalanx into sections, prevailed in the earliest times; but it is to the Greek writers that we must go for an account of the particular scales of subdivisions by which the evolutions of the phalanx on the field of battle were facilitated, and which, joined to the high discipline of the troops, gave to the body so denominated the reputation which it enjoyed till the fall of the Macedonian kingdom. The formation of such scales of subdivisions, and some changes in the arms or armour of the men, are probably what are meant when it is said that Lycurgus, Lysander, and Epaminondas introduced the *phalanx* among the Lacedæmonians, the Argives, and the Thebans. The Macedonian phalanx, the formation of which is ascribed to Philip, the father of Alexander, appears to have been a body of 6000 men, chosen for their good military qualities, particularly well armed, and subject to certain strict regulations. And its efficiency was so great, that it is styled a new invention by Diodorus, and the name of the country became afterwards very generally applied to it.

Xenophon, though constantly using the word *phalanx* in speaking of the whole body of troops which he commanded in the retreat from Cunaxa, when he has occasion to mention the formation or employment of a small body of men for any particular purpose, gives it the name of λόχος, and such body appears to have consisted either of 50 or 100 men. On one occasion, some lochi being detached from the army, two of them, amounting to 100 men, are said to have been cut off ('Anabasis,' lib. i.); and at another time, from an apprehension that the order of the phalanx would be broken in ascending a mountain, the army was divided into separate lochi of 100 men each. ('Ib.,' lib. iv.) But in the 'Cyropædia' (lib. ii.) a division of 100 men is called τάξις, and this is stated to have been subdivided into sections of ten and of five men each. The scale just hinted at was probably peculiar to the Athenian army, for Xenophon describes the Spartan troops as formed into six *μόραι*, each commanded by a polemarch; he adds also that the mora was divided into four λόχοι, eight πεντηκοστὺς, and sixteen ἐνωμοτίαι, in which the number of men appears to have varied, and to have consisted of from 25 to 36 men. ('De Repub.,' lib. xi.) The mora is said to have consisted of 600 men, but its strength appears to have varied considerably at different times. These were the divisions of the Spartan phalanx.

The only existing works expressly written on the subject of the Greek tactics are those of Ælian and his abbreviator Arrian, and these authors lived in the time of Hadrian and Antoninus, that is, long after the age in which the phalanx was superseded by the legion. Therefore, since their descriptions do not agree with what we find concerning the phalanx in the works of Thucydides and Xenophon, it seems reasonable to conclude that they appertain to the state of this body of troops in and subsequent to the times of Philip and Alexander. Ælian makes the Macedonian phalanx to consist of 16,384 men of the class called ὁπλῖται, or heavy-armed infantry; but this must be understood to be the whole body of that denomination in an army, and to be composed of four simple phalanges. Joined to the phalanx is a division (ἐπίταγμα), consisting of half that number of men of the class called ψιλοὶ, or light armed troops, and another, called also an epitagma, of cavalry (ἱππεῖς), consisting of one-fourth of the number.

The *peltastæ* (πελτασταὶ), who are also mentioned by Ælian, but not as appertaining to the phalanx, united in some measure the firmness of the heavy with the agility of the light armed men. They were first instituted by the Athenian commander Iphicrates, and in the course of time they became very numerous in the Greek armies: they served as the guards of the princes, and were often reckoned among the heavy-armed troops.

The simple phalanx, according to Ælian, consisted of 4096 men; one half of that number, or 2048 men, constituted the merarchy (*μεραρχία*); and one-fourth, or 1024 men, was called a chiliarchy (*χιλιαρχία*). One-fourth of the last constituted a syntagma (*σύνταγμα*), or xenagy (*ξεναγία*), which was a complete square of 16 men each way; and the lowest subdivision was called lochus (*λόχος*), decuria (*δεκὰς*), or enomoty (*ἐνωμοτία*), which is, by that writer, considered as a single file of 16 men. The officers do not appear to be included in the numbers of the different divisions: each xenagy had its own chief or captain (*συνταγματάρχης*) at the head, and a lieutenant (*οὐραγός*) brought up the rear. The leader of a single file is called by Ælian a decurion, perhaps because originally the file consisted of 10 men. A phalangarch commanded each phalanx.

Ælian divides the epitagma of light troops into sections, each of which has half the strength of the corresponding division in the phalanx; the lowest division is the iochus or file, which consists of 8 men. The epitagma of cavalry is divided in the same proportions as the bodies of infantry, down to the lowest subdivision, which is called *ἴλη*, and is made to consist of 64 men.

The phalangists were armed with helmet, cuirasses, and greaves; and in the early ages they carried an oval buckler and a pike, the latter about 10 feet long. The change introduced by Philip in the arms of the hoplitæ consisted in the substitution of a larger shield, and of the *σάρισσα*, a pike from 18 to 20 feet long. The arms of the peltastæ seem to have differed from those of the hoplitæ chiefly in the buckler (from whence their designation is derived) being round and only about two feet three inches in diameter, and in the pike being short. It is said that Iphicrates, instead of a metal cuirass, allowed to this class of troops only a corslet of strong linen; but apparently this regulation was not always followed. The light-armed troops were frequently provided with a helmet only, and their arms were small javelins, bows, or slings.

A phalanx, in line, was considered as being constituted of two equal parts or wings (*κέρατα*); there was no central division, but the place of junction of the two wings was called the *ὀμφαλὸς*. In the usual order of battle it was drawn up with its front parallel to that of the enemy, but it not unfrequently happened that one wing was kept retired. This last method was practised by Epaminondas at the battle of Leuctra; the wing engaged was strengthened so as to have 50 men in depth, and the line gradually diminished to the opposite extremity, where it was only six men deep. Sometimes also two phalanges advanced in columns, with their heads united, the two lines gradually diverging to the right and left; and this is that disposition which was called *ἔμζολον*, or the wedge.

The phalanx was frequently drawn up in the form of a quadrangle, which might be solid or hollow, according to circumstances; and this disposition was called the plinth (*πλινθίον*), or the plæsium (*πλαίσιον*). When a double phalanx was formed with their fronts in reversed positions, the order was called *αμφίστομος*. The order called *αντίστομος* seems to have been similar to the last, except that the men faced in opposite directions, from the centre towards the wings.

When standing at open order, each soldier in the phalanx was allowed a square space about six feet each way; but when prepared for action, this was reduced to three feet, and occasionally to about eighteen inches. The file-leaders and the rear-rank men were always chosen from the best of the troops, for on the first depended chiefly the success of the charge, and the latter performed the important duty of urging on the men immediately before him, in order that the whole body might not give way by the counter-pressure of the enemy's mass.

After the introduction of the Macedonian sarissa, above mentioned, the phalanx might present a formidable array of five ranks of such weapons projecting horizontally before the front of the line; for, admitting the men to be three feet from each other in depth, and that each man held in his hands about six feet of the length of the weapon, the point of that which belonged to the fifth man would project two feet beyond the file leader. Ælian also mentions another and perhaps a preferable practice, which was that of giving to the men from the first to the third or fourth rank spears successively longer in proportion to the distance of the rank from the front; in which case all those weapons must have projected equally before the line of troops.

The position of the phalanx was sometimes changed by a wheel of the whole body on either extremity as a pivot; and this was done with the men drawn up in close order. But the reversion of the front was performed in one of the three following ways:—The Cretan method, as it was called, consisted in making each file countermarch almost upon the ground it occupied, the file-leader going to the right-about, and moving to the rear, all the men of the file following him till the rear-rank man came into the line which was before the front. The Spartan method was also performed by a countermarch, but the file-leader moved to the rear, followed by the other men, till he arrived at a distance from his first place equal to twice the depth of the phalanx, the rear-rank man only changing his front. Lastly, the Macedonian method was performed by the front-rank man going right about on his own spot, the others passing him in succession and arranging themselves behind him. These movements appear to have been preferred by the Greeks to a simple change of front to be effected by making each man turn upon the ground he occupied, since they allowed the file-leaders to constitute always the foremost rank of the line.

The number of men in front of the phalanx was doubled by causing every second man in the depth to move up to the interval between every two men in the rank immediately before him; thus reducing the depth of the phalanx to eight files without extending the front. And when the front was to be extended without increasing the number of men in it, the troops merely, by a flank movement, opened out from the centre each way. Arrian justly observes that these evolutions should be avoided when in presence of the enemy; and he adds that it would be preferable to extend the front by bringing up cavalry or light troops to the wings.

On a march, the phalanx was thrown into a column, whose breadth depended on that of the road; and a formation of some separate bodies, consisting of 100 men each, for the purpose of protecting the main body while returning to its former order after having passed a defile, is mentioned by Xenophon ('Anabasis,' lib. iii.) as being then, for the first time, employed. The march of two phalanges in parallel and contiguous columns is stated to have been sometimes made by the columns keeping their proper fronts towards the exterior; but sometimes both columns were in like positions, the front of one and the rear of the other being towards the exterior, on the two sides of the line of march.

The strength of a Grecian army consisted in the deep array of its heavy infantry. No body of men less protected by defensive armour could make any impression upon the solid phalanx: and the latter, by the momentum of its charge, could not fail to overwhelm any troops who were differently formed. But the advantage of the phalanx, while it continued embodied, did not extend beyond the immediate field of battle; and the enemy, if he thought proper to decline an engagement, could, without interruption, except that which might arise from the light-armed troops and cavalry, ravage the country, and by cutting off its supplies compel the army to retreat. The phalanx moreover could only be advantageously employed on ground which was nearly level and free from obstacles; since whatever tended to derange its compact order, necessarily diminished or annulled the effect of its charge. At the battle of Issus, the phalanx of Alexander, while in a state of disorder, as the troops were passing the river, was engaged with the Greeks in the service of Darius; and though it succeeded in repelling the enemy, it sustained considerable loss. (Arrian, 'Exped. Alex.,' lib. ii.)

Polybius, in comparing (lib. xvii., extract 3) the efficiency of the phalanx with that of the Roman legion, observes that the latter never opposed the former on a line parallel to its front, but always with one wing thrown back; by which means it broke the line, or else compelled the phalanx to change its disposition; in either case there were formed intervals of which the legionary soldiers could avail themselves to engage the phalangists in flank, and thus render their close array and their unwieldy weapons useless.

PHANTASCOPE. An amusing toy based on the principle of the persistence of impressions on the retina, after the object has changed its position. The *Thaumatrope* and *Phenakistascope* rest on the same principle.

PHANTASMAGORIA. [MAGIC LANTERN.]

PHARISEES, a sect among the ancient Jews. The name is derived from the Greek Φαρισαῖοι, and this most probably from the Hebrew פָּרַשׁ, *parash*, to separate. Suidas says, "The Pharisees are by interpretation ἀφωρισμένοι (the separated), because they divided and separated themselves from all others, in exactness of life and in attention to the injunctions of the law."

The origin of this sect is unknown. Josephus, who was himself one of the Pharisees, speaks of them as flourishing long before he was born. He says ('Antiq.,' b. 13, c. 9), "At this time (about 150 B.C.) there were three sects of the Jews, the Pharisees, the Sadducees, and the Essenes." On several occasions he describes the Pharisees as the chief sect, and as possessing great authority among the people.

They believed in the existence of angels and spirits, and held the doctrine of the resurrection; but their notion of the latter appears to have been Pythagorean, namely, that there is a resurrection of the soul only by a transmigration into another body. From the benefits of this resurrection they shut out all the notoriously wicked, consigning them at once to eternal misery, upon the separation of the soul from the body. While the Essenes maintained that all things were ruled by absolute fate, and the Sadducees that all things were under human control, the Pharisees adopted a middle course, maintaining that some things were predestinated, and others left for men to determine. It was a leading maxim of the Stoics that some things were in our power, and others not in our power; and Josephus tells us that the sect of the Pharisees was very much like that of the Stoics.

But they were mainly distinguished by their zeal for "the traditions of the elders," to which they attached an importance equal to that of the Mosaic writings; and it was from a strict adherence to these traditions, as well as from an observance of the punctilios of the law itself, that they were called Pharisees. Several of these traditions are mentioned in the New Testament, but they are only a small portion of the whole. "To go through them all," says Prideaux, "would be to transcribe the Talmud, a book of twelve volumes in folio."

The Pharisees are represented in the New Testament as a hypocritical, proud, and arrogant people, pretending to be emphatically "the separated," trusting to themselves that they alone were righteous, and despising all other men. This was their character as a body; but there were among them individuals free from these bad qualities, such as Nicodemus, Joseph of Arimathæa, Gamaliel, and, as some think, Simeon, who uttered the hymn called "Nunc dimittis," to whom must be added Josephus, their historian.

(Josephus, *Antiq.*, xiii. 9, 18; xvii. 3; xviii. 2; *De Bell. Jud.*, ii. 7; *De Vitâ suâ*; Suidas, Φαρισαιοι; Prideaux, *Connection*; Jahn, *Heb. Ant.*, b. iii., c. 1, §§ 316–20.)

PHARMACOPŒIA, a book published by the colleges of physicians with the sanction of government, containing directions for the preparation of medicines.

PHA'RMACY, in a comprehensive sense, means the department of natural science which treats of the collection, preparation, and preservation of medicines, and also of the art of dispensing them according to the formulæ or prescriptions of medical practitioners. It is however more commonly used in a limited sense, as a branch of chemical science, and termed pharmaceutical chemistry, or the application of the laws of chemistry to those substances which are employed for the cure of diseases, so as to render them more commodious, or their administration more easy, and their action more perfect and certain. It should not be understood as merely depending upon some mechanical processes, such as trituration, rasping, or other means of subdivision, or even the simpler chemical actions involved in the processes of infusion or decoction, but as requiring a knowledge of vegetable physiology, and an acquaintance with the chemical constitution of the substances to be prepared. In many continental nations this department is the subject of very strict legal enactments, and forms an important part of medical police, especially as regards the dispensing of poisonous drugs; while in Britain any one who chooses may affix the terms chemist and druggist to his name, and may deal in the most useful or dangerous ingredients, without that previous education which would fit him to be the appropriate assistant to the physician, whose most judicious plans are often frustrated by the ignorance or carelessness of those to whom the compounding of his prescriptions are entrusted. Efforts are making both in parliament and out, by the Sale of Poisons bill, and other measures, and still more by the precautionary exertions of the Pharmaceutical Society, founded by the late Jacob Bell to remove this reproach. [MATERIA MEDICA.]

PHASE (*φάσις, phasis*, appearance). When a phenomenon changes its character gradually, any particular state which it is necessary to distinguish is called a phase. Thus we have the phases of the moon, meaning the different forms which the enlightened part takes during the month; the phases of the weather, meaning the succession of heat and cold, wet and dry, &c.

PHASES OF THE MOON. [MOON.]

PHENAMIDE. [ANILINE.]

PHENAMYLOL. [PHENYLIC GROUP.]

PHENATES. [PHENYLIC GROUP.]

PHENETOL. [PHENYLIC GROUP.]

PHENIC ACID. [PHENYLIC GROUP.]

PHENIC ALCOHOL. [PHENYLIC GROUP.]

PHENYL. A prefix used in organic chemistry to denote the presence of the radical phenyl in the compound to the name of which it is added. Descriptions of such bodies will generally be found under the name of the compound to which it is prefixed.

PHENYLAMINE. [PHENYLIC GROUP.]

PHENYL-BENZAMINE. [BENZOIC GROUP.]

PHENYL-BIBENZAMINE. [BENZOIC GROUP.]

PHENYL-CAMPHORAMIC ACID. [CAMPHOR.]

PHENYL-CAMPHORAMIDE. [CAMPHOR.]

PHENYL-CARBAMIC ACID ($C_{14}H_7NO_4$) *Carbinilic acid, Anthranilic acid.* The action of potash upon indigo or phenyl-urea produces phenyl carbamic acid, which crystallises in colourless prisms, slightly soluble in cold water, but easily dissolved by hot water.

PHENYL, CYANIDE OF. [BENZOIC ACID.]

PHENYL-FORMIAMIDE. [FORMYL.]

PHENYLIC GROUP. This is one of the groups of organic compounds that belong to the BENZOIC SERIES. It includes a great number of substances, of which the chief are at present only scientifically interesting, at the same time many are employed in the arts; as for example, aniline, benzole, and carbolic and carbazotic acids.

Phenyl ($C_{12}H_5$) is the radical contained in, or from which are derived, all the members of the phenylic group. It and its derivatives somewhat resemble methyl and the compounds of methyl. While methyl, however, belongs to those radicals having the general formula C_nH_{n+1}, phenyl obviously belongs to those of the general formula C_nH_{n-7}. Phenyl itself has not yet been isolated.

Hydride of phenyl ($C_{12}H_5$, H), *phene* or *benzole* or *benzine*, has already been treated of in a separate article [BENZOLE]. Under the same head are also described the chlorine, bromine, and peroxide of nitrogen, derivatives of hydride of phenyl. The peroxide of nitrogen derivative, or *nitrobenzol* $\left(C_{12}\left\{\begin{matrix}H_4\\NO_4\end{matrix}\right\}, H\right)$ yields AZOXIBENZIDE on being heated with alcoholic solution of potash; and azoxibenzide yields AZOBENZIDE by distillation. By the action of reducing agents, such as sulphide of ammonium, azoxibenzide, and azobenzide yield *benzidine* ($C_{24}H_{12}N_2$). Benzidine occurs in lustrous white plates, soluble in boiling water, alcohol, or ether. With acids it forms crystalline salts from solutions of which caustic alkalies throw down a white precipitate of benzidine.

Hydrated oxide of phenyl ($C_{12}H_5O$, HO). *Phenic acid. Phenic alcohol. Phenol. Carbolic acid.* This body is produced in the manufacture of coal gas; hence, the name *phenic*, and thence *phenyl*, from the Greek *φαινω*, "I light," in allusion to the use of coal gas. The method of isolating, and the properties of phenic alcohol have already been detailed [CARBOLIC ACID.] It combines with bases to form *phenates*, some of which are crystalline.

By the ordinary processes of substitution, phenic acid gives rise to the bodies whose names and formulæ are here appended. Many of them were discovered by Laurent, who gave them peculiar, but convenient, names on a principle already alluded to under NAPHTHALIC GROUP.

Phenic or carbolic acid	HO, $C_{12}(H_5)$, O
Bichlorophenic acid or chlorophenesic acid . .	HO, $C_{12}(H_3Cl_2)$, O
Trichlorophenic acid, or chlorophenisic acid, or chlorindoptic acid	HO, $C_{12}(H_2Cl_3)$, O
Pentachlorophenic acid or chlorophenusic acid . .	HO, $C_{12}(Cl_5)$, O
Bromophenic acid or bromophenasic acid . .	HO, $C_{12}(H_4Br)$, O
Bibromophenic acid or bromophenesic acid . . .	HO, $C_{12}(H_3Br_2)$, O
Tribromophenic acid, or bromophenisic acid, or bromindoptic acid	HO, $C_{12}(H_2Br_3)$, O
Nitrophenic acid or nitrophenasic acid . . .	HO, $C_{12}(H_4NO_4)$, O
Bichloronitrophenic acid or chloronitraphenisic acid	HO, $C_{12}(H_2Cl_2NO_4)$, O
Bi-iodonitrophenic acid or iodenitraphenisic acid .	HO, $C_{12}(H_2I_2NO_4)$, O
Binitrophenic acid or nitrophenesic acid . .	HO, $C_{12}(H_3 2NO_4)$, O
Bromobinitrophenic acid or bromanitrephenisic acid	HO, $C_{12}(H_2Br 2NO_4)$, O
Trinitrophenic acid, picric acid, or nitrophenisic acid, or CARBAZOTIC ACID	HO, $C_{12}(H_2 3NO_4)$, O
Picranisic acid (isomeric with trinitrophenic acid) .	HO, $C_{12}(H_2 3NO_4)$, O

Binitrophenic acid and trinitrophenic acid respectively yield *nitrophenamic acid* ($C_{24}H_{12}(NO_4)_2N_2O_4+4Aq$), and *picramic acid* ($C_{12}H_5(NO_4)_2NO_2$) when acted upon by sulphide of ammonium. All these acids form with bases salts that mostly are crystalline.

Phenic acid combines with the oxides of methyl, ethyl, and amyl to form :—

1. Phenate of methyl	$\left.\begin{matrix}C_{12}H_5O\\C_2H_3O\end{matrix}\right\}$
2. Phenate of ethyl	$\left.\begin{matrix}C_{12}H_5O\\C_4H_5O\end{matrix}\right\}$
3. Phenate of amyl	$\left.\begin{matrix}C_{12}H_5O\\C_{10}H_{11}O\end{matrix}\right\}$

1. Phenate of methyl or *anisol* is prepared by distilling anisic acid with caustic baryta. Its sp. gr. is 0·991. Boiling point 305·6° Fahr. By substitution it yields

Bibromphenate of methyl or bibromanisol .	$\left.\begin{matrix}C_{12}(H_3Br_2)O\\C_2H_3O\end{matrix}\right\}$
Nitrophenate of methyl or nitranisol . . .	$\left.\begin{matrix}C_{12}(H_4NO_4)O\\C_2H_3O\end{matrix}\right\}$
Binitrophenate of methyl or binitranisol .	$\left.\begin{matrix}C_{12}(H_3 2NO_4)C\\C_2H_3O\end{matrix}\right\}$
Trinitrophenate of methyl or trinitranisol .	$\left.\begin{matrix}C_{12}(H_2 3NO_4)O\\C_2H_3O\end{matrix}\right\}$
CHRYSANISIC ACID (isomeric with trinitranisol)	$\left.\begin{matrix}C_{12}(H_2 3NO_4)O\\C_2H_3O\end{matrix}\right\}$

The nitro-, binitro-, and trinitro-phenate of methyl yield the three following bodies by the action of sulphide of ammonium.

Methyl-phenidine or ANISIDINE . . .	$C_{14}(H_9)NO_2$
Methylnitrophenidine or nitranisidine . .	$C_{14}(H_8NO_4)NO_2$
Methylbinitrophenidine or binitranisidine .	$C_{14}(H_7 2NO_4)NO_2$

Sulphuric acid converts phenate of methyl into *methylsulphophenic acid* $\left(\left.\begin{matrix}C_{12}(H_4, C_2H_3) & O\\ & HO\end{matrix}\right\} S_2O_6\right)$ called also *sulphanisolic acid*, while anhydrous sulphuric acid transforms it into *sulphanisolide*.

2. Phenate of ethyl, *phenetol* or *salithol*, is prepared by submitting to distillation the perfectly dry compound of salicylate of ethyl with baryta. It is a colourless liquid, lighter than water, of agreeable aromatic odour, very soluble in alcohol or ether, but insoluble in water. It boils at 341·6° Fahr. Chlorine and bromine convert it into

crystalline products. Fuming nitric acid attacks and forms consecutively :—

Nitrophenate of ethyl or nitrophenetol .	?
Binitrophenate of ethyl or binitrophenetol .	$\left.\begin{matrix}C_{12}(H_3 2NO_4)O\\ C_4H_5O\end{matrix}\right\}$
Trinitrophenate of ethyl or picric ether .	?

Binitrophenate of ethyl yields *ethyl-nitrophenidine* or nitrophenetidine ($C_{16}(H_{10}NO_4)NO_2$) by the action of sulphide of ammonium.

3. Phenate of amyl or *phenamylol* is formed on heating a mixture of phenate of potash and iodide of amyl in a sealed tube to a temperature of about 220° Fahr. It is a limpid, colourless oil, of agreeable odour. Its boiling point is about 436° Fahr. Nitric acid strongly attacks it, and the resulting compound yields *amyl-nitrophenidine* by the action of sulphide of ammonium.

Oxyphenic acid. ($C_{12}H_6O_4$) *Binoxide of phenyl; pyrocatechin; pyromorintannic acid.* This body is a product of the dry distillation of CATECHU or of morintannic acid [TANNIC ACID.] The aqueous portion of the distillate is evaporated and set aside; the impure oxyphenic acid that deposits may be purified by recrystallisation from water, and finally by sublimation.

Oxyphenic acid crystallises in colourless rectangular prisms; it is very soluble in water or alcohol, but only slightly so in ether.

Trinitroxyphenic acid. ($C_{12}(H_3\ 3\ NO_4)O_4$) *Oxypicric acid. Styphnic acid.* The composition of this body indicates it a derivative of oxyphenic acid, but the latter body does not yield it on being acted upon by nitric acid. It is most readily obtained by acting upon asafœtida or extract of Brazil-wood with nitric acid; many other gum-resins also yield it under similar circumstances. The liquid product of the action of nitric acid upon these bodies is neutralised with carbonate of potash and crystals of styphnate of potash obtained by evaporation; these may be recrystallised from a small quantity of boiling water or the styphnic acid precipitated by nitric acid. Brazil-wood extract furnishes about 18 per cent. of styphnic acid. It may be obtained in large yellow prismatic crystals from solution in alcohol. It combines with acids to form crystalline salts, called *styphnates* or *oxypicrates*. They all explode violently when gently heated.

Sulphites of phenyl. Hydride of phenyl dissolves in fuming sulphuric acid, and forms *phenylsulphurous* or *sulphobenzidic acid*, $\left.\begin{matrix}C_{12}H_5S_2O_4, O\\ H\ O\end{matrix}\right\}$. It may be looked upon as the hydrated oxide of the radical *sulphophenyl* ($C_{12}H_5S_2O_4$). It forms extremely stable salts with acids called *phenylsulphites*, or *sulphobenzidates*. Nitric acid converts it into *nitrophenylsulphurous* or *nitrosulphobenzidic acid*, $\left.\begin{matrix}C_{12}(H_4NO_4)S_2O_4, O\\ H\ O\end{matrix}\right\}$.

Chloride of sulphophenyl ($C_{12}H_5S_2O_4$, Cl) is a colourless oil, of sp. gr. 1·378, and boiling point 489·2 It is formed on distilling phenylsulphite of soda with oxychloride of phosphorus. It is readily attacked by ammonia, with production of *sulphophenylamide;* and the latter, by the ordinary process of substitution, yields the following primary, secondary, and tertiary monamides, including a tertiary diamide :—

Sulphophenylamide	$N\begin{cases}C_{12}H_5S_2O_4\\ H\\ H\end{cases}$
Sulphophenylargentamide	$N\begin{cases}C_{12}H_5S_2O_4\\ Ag\\ H\end{cases}$
Disulphophenylamide	$N\begin{cases}C_{12}H_5S_2O_4\\ C_{12}H_5S_2O_4\\ H\end{cases}$
Sulphophenylsuccinylamide	$N\begin{cases}C_{12}H_5S_2O_4\\ (C_8H_4O_4)''\end{cases}$
Sulphophenylbenzoylamide . . .	$N\begin{cases}C_{12}H_5S_2O_4\\ C_{14}H_5O_2\\ H\end{cases}$
Sulphophenylbenzoylargentamide . . .	$N\begin{cases}C_{12}H_5S_2O_4\\ C_{14}H_5O_2\\ Ag\end{cases}$
Sulphophenyldibenzoylamide . . .	$N\begin{cases}C_{12}H_5S_2O_4\\ C_{14}H_5O_2\\ C_{14}H_5O_2\end{cases}$
Sulphophenylbenzoylacetylamide . . .	$N\begin{cases}C_{12}H_5S_2O_4\\ C_{14}H_5O_2\\ C_4H_3O_2\end{cases}$
Sulphophenylcumylamide	$N\begin{cases}C_{12}H_5S_2O_2\\ C_{20}H_{11}O_2\\ H\end{cases}$
Sulphophenylbenzoylcumylamide . . .	$N\begin{cases}C_{12}H_5S_2O_4\\ C_{14}H_5O_2\\ C_{20}H_{11}O_2\end{cases}$
Sulphophenylbenzolsuccinyldiamide . .	$N_2\begin{cases}(C_{12}H_5S_2O_4)_2\\ (C_{14}H_5O_2)_2\\ (C_8H_4O_4)''\end{cases}$

Phenylide of sulphophenyl, or *sulphobenzide* ($C_{12}H_5S_2O_4$, $C_{12}H_5$), is also a product of the action of fuming sulphuric acid upon hydride of phenyl. Unlike phenylsulphurous acid, however, it remains insoluble when the product referred to is diluted with water.

Sulphate of phenyl $\left(\left.\begin{matrix}C_{12}H_5O\\ H\ O\end{matrix}\right\} S_2O_6\right)$. *Sulphophenic* or *phenylsulphuric acid.* A combination of phenic and sulphuric acids. It forms crystalline salts with ammonia and baryta.

Chloride of phenyl, or *chlorhydrophenide* ($C_{12}H_5$, Cl). A product of the action of oxychloride of phosphorus on phenic acid. It is an almost inodorous liquid, heavier than water.

Chloride of binitrophenyl, or *binitrochlorhydrophenide* ($C_{12}(H_3 2NO_4)$, Cl), is produced on acting upon binitrophenic acid with perchloride of phosphorus. It much resembles chloride of phenyl.

Aniline, phenylia, or phenylamine $\left(N\begin{cases}C_{12}H_5\\ H\\ H\end{cases}\right)$, and its numerous interesting derivatives, will be found described in a separate article [ANILINE], or under ORGANIC BASES.

Cyanide of phenyl ($C\ {}_2H_5Cy$). *Benzonitrile.* Obtained by the distillation of dried benzoate of ammonia, as described under BENZOIC ACID. It a colourless oil, having an odour resembling that of bitter almond oil. It is soluble in alcohol or ether, but almost insoluble in water. Its sp. gr. is 1·0073; boiling point, 376° Fahr. Fuming nitric acid converts it into *cyanide of nitrophenyl* ($C_{12}(H_4NO_4)$, Cy), or *nitrobenzonitrile.*

PHENYL-PHTHALIMIDE. [NAPHTHALIC GROUP.]

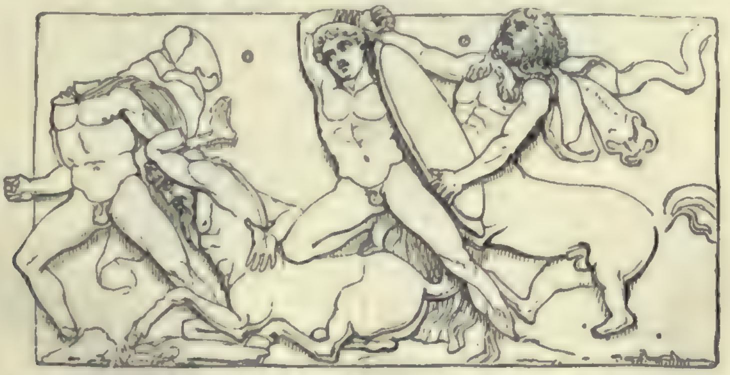
PHENYL-SULPHURIC ACID ($C_{12}H_6S_2O_8$). *Sulphophenylic acid.* A monobasic acid bearing the same relation to phenylic alcohol as sulphovinic acid sustains towards common or vinic alcohol.

PHENYL-SULPHUROUS ACID ($C_{12}H_6S_2O_6$). *Sulphobenzidic acid.* A crystalline organic acid, obtained by gently heating benzole with its own volume of sulphurous acid. Its salts are monobasic and very stable.

PHIAL, LEYDEN. [ELECTRICITY.]

PHIGALIAN MARBLES, a series of sculptures in alto-rilievo, preserved in the British Museum, which are so called from having been discovered among the ruins of a temple at the ancient Bassæ on Mount Cotylion, not far from the site of Phigalia. The subjects represented in them are the battle of the Centaurs and Lapithæ, which occupies eleven slabs, and that of the Greeks and Amazons, in twelve slabs. The height of each is 2 feet 1 inch, and the whole length about 100 feet. These rilievi formed a frieze round the interior of the cella, and were elevated about 22 feet from the ground.

Fig. 1.



Pausanias (viii. 41), describing the edifice from which these marbles were brought, says, "After that at Tegea, it may be considered the most beautiful of all the temples of the Peloponnesus." The roof of the building was of stone. It was dedicated to Apollo Epicurius, or the *Deliverer*, a title conferred upon him because he had delivered the Phigalians from a pestilence.

These sculptures are of various degrees of merit as regards execution;

but the composition, expression, and style of art prove that they came from a fine school of design. The evidence of this in the works themselves is confirmed by the history (which has fortunately reached our times) of the temples which they decorated. The name of the architect was Ictinus, the same who, when Phidias was appointed to superintend the various public works carried on at Athens during the administration of Pericles, was associated with Callicrates to erect the Parthenon—one of the most splendid monuments of the golden age of art. This gives us the proximate date of the execution of the sculptures under consideration. The Parthenon was finished about 437 B.C. The temple of Apollo at Bassæ may therefore be attributed to about the same period.

Fig. 2.

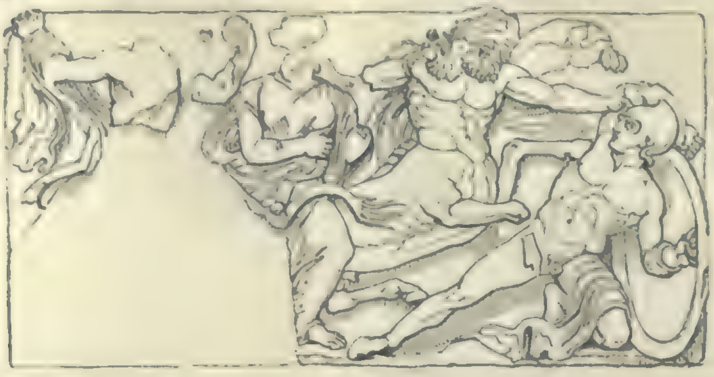


Fig. 3.

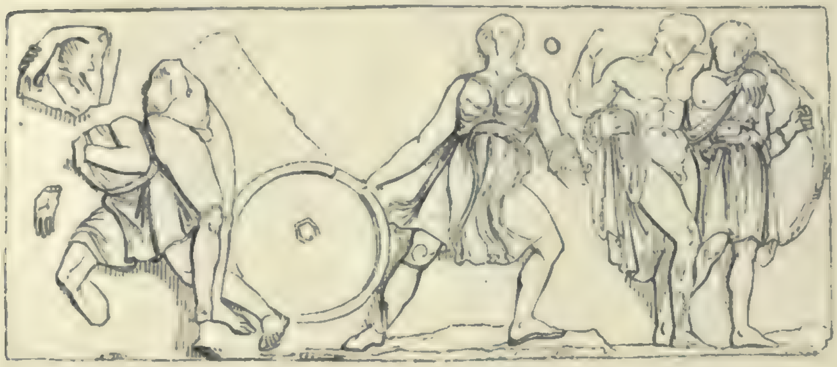

Fig. 4.

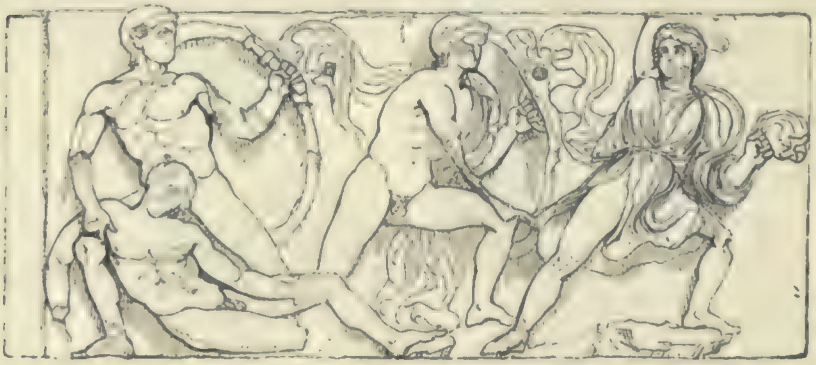

Fig. 5.

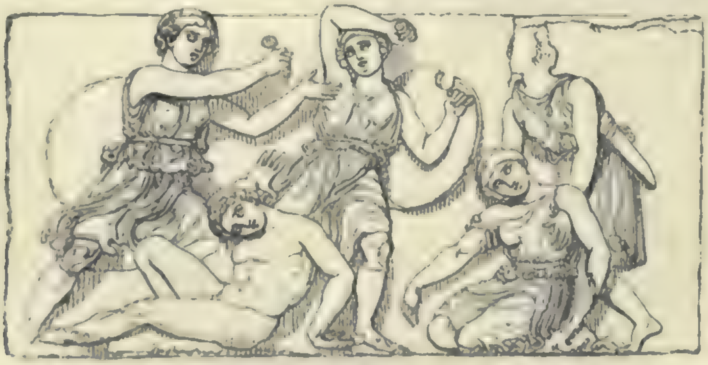

The quality of the design of these rilievi warrants the assumption that the eminent sculptor who directed the decoration of the former great work of Ictinus may have contributed the advantage of his skill by suggesting the fine compositions of the sculptures for his present undertaking. It is not difficult to discern in them the same sentiment and character which pervade the marbles of the Parthenon. This correspondence is particularly observable in comparing portions of the Phigalian frieze with the metopes of that building (see *figs.* 1 and 2 [Phigalian Marbles]; the third cut in the article CENTAUR, which is one of the Phigalian series; and *fig.* 1 under ELGIN MARBLES), where the same subject, the battle of the Centaurs and Lapithæ, is represented. The same may be remarked with respect to other parts of this fine series, whether it be considered for the energy displayed in violent action (*figs.* 1, 2, and 4; and the cut in the article CENTAUR), for grace and tenderness where gentler expression is to be conveyed (*figs.* 3 and 5), for playful flow of lines (as in groups in *figs.* 3 and 4), or for the just balancing of parts as the means of producing a harmonious whole. Throughout there is the stamp of careful thought, and evidence of an intimate knowledge of art, combined with a free and bold style. Among the excellencies of *treatment*, as it is technically called, the value and quality of flesh and drapery in contrast, are finely exhibited in parts of *figs.* 3 and 4. The few specimens here chosen for illustration are sufficient to show the claim these marbles have to our admiration as compositions. The difference alluded to in the merit of the execution may probably be owing to the working out of the general design having been entrusted either to pupils or to various and inferior artists, the idea and the compositions alone being furnished by the master-mind.

These interesting specimens of Greek sculpture were discovered in the year 1812. They were purchased for the British Museum in 1814, and arrived in England in the following year. The slabs were found, with two or three exceptions, lying on the floor or pavement of the temple, under the identical places they had originally occupied. They were much mutilated, both from the injury they had sustained from their own weight in falling, and from the heavy masses of the building which had fallen on them. They have been put together with great care, the pieces being secured by copper bolts; but in no instance has their integrity been impaired by restorations. For detailed descriptions of these marbles, the reader is referred to the elaborate work of Baron von Stackelberg, 'Der Apollotempel zu Bassæ in Arcadien,' &c., Rome, 1826; also to Part IV. of 'Description of the Ancient Marbles in the British Museum;' and to the 'Elgin Marbles,' in the 'Library of Entertaining Knowledge.'

PHILIPPIANS, EPISTLE TO THE, is one of the epistles written by St. Paul during his first imprisonment at Rome. [Paul, St., in Biog. Div.] Like the other early churches planted out of Palestine, the church at Philippi in Macedonia consisted of Jews and Gentiles, the latter forming the larger portion. These Philippians must, however, have had cultivated minds, and have been acquainted with the manners, customs, and philosophy of the Greeks, since the epistle contains allusions the force of which no other persons could fully understand. They were first converted by the preaching of St. Paul about twelve years before the date of this epistle, which was written apparently (ii. 24) but a short time before his release from his imprisonment at Rome, A.D. 63.

The occasion of its composition seems to have been the following: the Philippians, having heard that St. Paul was a prisoner at Rome, sent contributions for his relief by the hand of Epaphroditus, whom Theodoret and others represent as their bishop. St. Paul, being much rejoiced by this proof of their affection towards him, and by learning how great was their proficiency in all Christian excellences, sends back Epaphroditus with this epistle.

In this epistle, of which the canonical authority is incontestable, St. Paul discovers much of his own character, the traits of which cannot fail to create in the mind of an attentive reader an idea of true dignity. He delicately proposes his own conduct for the imitation of the Philippians; and, with no mixture of affected humility, he disclaims all personal merit for whatever wisdom or goodness they had seen in him or heard of him. His language is for the most part constructed with great skilfulness; his thoughts are arranged in an order exactly suited to his design; and his manner is at once affectionate and authoritative.

PHILIPPICS. [Demosthenes, in Biog. Div.]

PHILLIRIN ($C_{54}H_{34}O_{22} + 3$ Aq.) A white crystalline substance of a silvery lustre found in the bark of the *Phillyrea latifolia*. It is inodorous, bitter, slightly soluble in cold water, moderately so in boiling water or alcohol, and nearly insoluble in ether. Boiled with dilute hydrochloric acid it is transformed into phillygenin (a resinous substance of the formula $C_{42}H_{24}O_{12}$) and grape sugar.

$$\underbrace{C_{54}H_{34}O_{22}}_{\text{Phillyrin.}} + 2HO = \underbrace{C_{42}H_{24}O_{12}}_{\text{Phillygenin.}} + \underbrace{C_{12}H_{12}O_{12}}_{\text{Grape sugar.}}$$

PHILO'LOGY (*φιλολογία*). It is difficult to attach a precise meaning to this word, as it is used in different significations by different writers. Among the Greeks and Romans, the term philology was originally used to signify a love for the investigation of all subjects connected with literature (Plat., 'Theaet.,' c. x. p. 146; c. xlvii. p. 161; Cic. 'ad Div.' xvi. 21; Ernesti, 'Clavis Ciceron.,' under *φιλολογωτερα*.) The Alexandrine critics applied the term philologus to a person who was well acquainted with the ancient Greek writers, and with the subjects treated of in their works; and we learn from Suetonius ('De Illustr. Grammat.,' c. 10), that Eratosthenes, who lived in the 2nd century before the Christian era, was the first who obtained this name, in consequence of his extensive and varied learning. In later times, a philologus was merely a person skilled in language, and the word became almost synonymous with grammaticus.

Some modern writers have included under the term philology the study of Greek and Roman antiquities, but the majority of writers appear to regard the study of the theory of language and of languages in general as the only subjects strictly belonging to philology.

The reader who wishes further information respecting the different meanings attached to the word philology, may consult Ast's 'Grundriss der Philologie,' Landshut, 1808; and the first essay in Wolf and Buttmann's 'Museum der Alterthums-Wissenschaft,' Berlin, 1807.

PHILOSOPHY, from the Greek *philosophia* (φιλοσοφια). literally signifies "love of wisdom or knowledge," and a philosopher (φιλόσοφος), is a "lover of wisdom." Pythagoras (Diog. Laert., *Procem.*) is said to have first used the term philosophy, and to have called himself a philosopher, instead of a sophus (σόφος), or "wise man," for, he added, no one is wise but God. Among the Greeks, philosophy was sometimes viewed as comprising or consisting of three parts, physic (φυσικόν), ethic (ἠθικόν), and dialectic (διαλεκτικόν). Physic treated of the universe and that which it contained; ethic treated of things that concerned human life and man. The term dialectic is explained in the article Organon.

The terms philosophy, philosophical, philosopher, are often used in our own language apparently with no great precision, though it is not difficult to deduce from the use of these terms the general meaning or notion which is attached to them. We speak of the philosophy of the human mind as being of all philosophies that to which the name philosophy is particularly appropriated; and when the term philosophy is used absolutely, this seems to be the philosophy that is spoken of. Other philosophies are referred to their several objects by qualifying terms; thus we speak of natural philosophy, meaning thereby the philosophy (whatever that word may mean) of nature, that is, as the term nature is generally understood, of material objects. We also speak of the philosophy of positive law, understanding thereby the philosophy of those binding rules, properly called laws. The terms philosophy of history, philosophy of manufactures, and other such terms, are also used. All objects then which can occupy the mind may have something in common, called their philosophy; which philosophy is nothing else than the general expression for that effort of the mind whereby it strives, pursuant to its laws, to reduce its knowledge to the form of ultimate truths or principles, and to determine the immutable relations which exist between things as it conceives them. The philosophy which comprises within itself all philosophies is that which labours to determine the laws or ultimate principles in obedience to which the mind itself operates; and both those laws or ultimate truths, which must be considered as constituting the mind what it is, and which are therefore independent of all external impressions, and those laws by which the mind operates upon the sensuous impressions produced by objects which it conceives and can only conceive as being external to itself.

Thus every kind of knowledge, the objects of which are things external, has its philosophy or principles, which, when discovered and systematised, form the science of the things to which they severally belong. But inasmuch as the mind, in striving after this science, must act by its own laws and powers, and as these must in their form, viewed independently of their special objects, always be the same laws and powers (for we cannot conceive the mental powers to vary or differ in their essential qualities merely because they are applied to things that are conceived as different), we therefore assume that the mind has its laws and powers, which may be discovered by observation, as we discover by observation the laws or principles which govern the relations of things external to the mind, or conceived as external. Thus the human mind, by the necessity imprinted upon it, seeks to discover the ultimate foundation of all that it knows or conceives; to discover what itself is, and what is its relation to all things. Accordingly it strives to form a system out of all such ultimate laws or principles. Such a system may be called a philosophy, in the proper and absolute sense of the term, and the attempt to form such a system is to philosophise. Systems of philosophy have existed in all nations; even in the most uncivilised, in some form, and particularly in the form of a religion; for the highest aim of philosophy is to ascertain the relation of man to the infinite Being whom he conceives as the end and limit of all his inquiries. In nations which have made further progress in mental culture, the systems of philosophy are not limited to the dogmas of a religion, but those who have leisure, and whose minds have been disciplined, have in all ages ventured to transcend the limits of the religious system of their society or age, and to form what are called philosophical systems. The history of such systems is the history of philosophy, which thus viewed is a history of the progress of the human mind towards the knowledge of itself, a knowledge which, imperfect as it is, is the accumulation of many centuries, and the work of many contributors.

PHILOSOPHY OF THE HUMAN MIND. [Metaphysics.]

PHILOSOPHY, POSITIVE. The distinction of philosophy as positive and negative, was adopted by the German school. Thus Kant's 'Kritik der Reinen Vernunft,' his 'Prolegomena zu einer jeden Künftigen Metaphysik,' and his 'Kritik der Urtheilskraft,' are regarded as forming a sort of Prima Philosophia, preparatory to a positive or formal and detailed system of metaphysics. For though the philosophies which have successively arisen in Germany since Kant's day, such as the Scientific-doctrine of Fichte, the Transcendental Idealism of Schelling, the Phenomenology and Logic of Hegel, or the Metaphysic of Herbart, are all genealogically descended from Kant's Critical review (the review which reason was made by him to engage in, of the faculties of the soul), yet Kant himself, in his Kritik, did not profess to do more then pave the way for a system or dogmatik of speculative philosophy. Kant's main question proposed for solution in the criticism of reason was, "are metaphysics possible?" or, are synthetic judgments *à priori* possible?—judgments, or propositions, that is—the truth of which is not learned from experience, and which also are not merely analytical, or judgments in which the predicate barely unfolds the subject. Thus "all body is extended," is an analytical judgment: "all men are mortal," is synthetical indeed, but then it is *à posteriori*, being founded on experience: but, "every change must have a cause," is synthetical *à priori*, being universal and necessary, and founded in nothing but "pure understanding and reason." Now all such axioms, conceptions, and principles as are *à priori*, being enumerated, are regarded by those who make a distinction between positive and negative philosophy, as forming a negative philosophy, or as drawing the ground for a positive constructive system. Kant held out the expectation of such a system, as a superstructure to be erected by himself on the basis of the 'Kritik:' such a system of pure speculative reason I hope "to furnish myself, under the title, Metaphysic of Nature; which shall have far richer matter than this Kritik, though the latter was necessary, first to exhibit the sources and conditions of its possibility, and to cleanse and level a soil altogether overgrown with weeds." ('Kritik:' Vorrede.) Such a system would have been, in the German phrase, a positive philosophy: but the Transcendental Criticism professes only to examine and secure the foundation on which, the author says, "every future metaphysic" must be built, and is, relatively to such supposed system, merely negative.

The Positive Philosophy that Kant and the German metaphysicians only contemplated was at length propounded by M. August Comte, in his 'Cours de Philosophie Positive,' in 1830-1842, and his 'Discours sur l'Ensemble du Positivisme,' 1848. According to his system the human mind has passed through certain stages: the *theological*, in which supernatural agencies are necessary; the *metaphysical*, in which supernatural aids are dismissed, and their place supplied by abstract ideas. These stages he deems incorrect, and holds that the mind now arrives at the last and highest stage the *positive*, in which it grasps all that can be known with certainty, such as scientific truths, and holds that in other more complex subjects, such as Biology and Sociology (social science), definite laws prevail which may be ultimately discovered by strict observation and deduction, and that nothing is to be believed that cannot be proved. [COMTE, in BIOG. DIV.]

PHILTER (*φίλτρον, philtrum*), was a potion given among the Greeks and Romans to excite love. It is doubtful of what these potions were composed, but their operation was violent and dangerous, often depriving those who drank them of their reason. (Ovid, 'Ar. Amat.,' ii. 106.) Lucretius is said to have died from drinking a potion of this kind; and the madness of Caligula is attributed by some to a similar potion, which was given him by his wife Cæsonia. (Suet., 'Cal.,' 50; Juv., vi. 615, 616.) The most powerful love potions were prepared by the Thessalians, whence Juvenal speaks (vi. 610) of Thessala philtra.

PHLOGISTICATED AIR. An obsolete name for NITROGEN.

PHLOGISTON, an hypothetical substance, by supposing the existence of which Stahl [STAHL, in BIOG. DIV.] explained the phenomena of combustion. He imagined that by combination with phlogiston a body was rendered combustible, and that its disengagement occasioned combustion, and after its evolution there remained either an acid or an earth: thus sulphur was by this theory supposed to be composed of phlogiston and sulphuric acid; and lead, of the calx of lead and phlogiston, &c.

At this period, however, oxygen had not been discovered, and although Jean Rey had shown that metals by burning increased in weight, and Hooke and Mayow had attributed combustion to the presence of the air in which it occurs, yet the doctrine proposed by Stahl maintained its ground for about half a century. Soon after the discovery of oxygen gas by Dr. Priestley, the experiments which others had made on the calcination of the metals were repeated with great accuracy by Lavoisier; the consequence was, that the phlogistic theory gave way to the antiphlogistic; for the combustion, which had been attributed to the extrication of phlogiston, was known in all common cases to be derived from the absorption of oxygen, and this explained the increase of weight which bodies acquired by combustion, whereas on the phlogistic theory they ought to have suffered a diminution by the process.

PHLORETIC ACID. [PHLORIZIN.]

PHLORETIN. [PHLORIZIN.]

PHLORIDZIN. [PHLORIZIN.]

PHLORIZEIN. [PHLORIZIN.]

PHLORIZIN ($C_{42}H_{24}O_{20}+4$ Aq.) *Phloridzin*, a peculiar vegetable matter which exists in the bark of the trunk and roots of the apple, pear, cherry, and plum trees. According to Stass it is most readily obtained, and in large quantity, by treating either the fresh or dried roots of the apple tree with weak alcohol at the temperature of about 150° Fahr. When the digestion has been continued for some hours, the clear solution is to be poured off, and the alcohol distilled; the residual liquor on cooling deposits phlorizin, which is to be rendered colourless by animal charcoal.

Phlorizin, when deposited from a saturated solution, has the form of silky tufts; but when obtained by the slow cooling of a dilute solution, it is in long flat brilliant needles. The taste of phlorizin is rather bitter, followed with slight sweetness; it is scarcely soluble in cold water, but boiling water dissolves it in large quantity; alcohol and pyroxylic spirit also readily take it up, and at all temperatures; ether, even when boiling, dissolves only traces of it, though, when mixed with alcohol, it dissolves it very well; it has no action on vegetable colours.

Phlorizin is by various processes, described by M. Stass, converted into *phlorizein* ($C_{42}H_{30}N_2O_{26}$), *phloretin* ($C_{30}H_{14}O_{10}$), *Phloroglucin* ($C_{12}H_6O_6+4$ Aq.), *Rufin* ($C_{42}H_{20}O_{16}$), *phloretic acid* (C[illegible]$H_{13}(NO_4)O_{10}$?); for an account of these, we refer to his memoir contained in the 69th vol. of 'Annales des Chimie et de Physique.'

PHLOROGLUCIN. [PHLORIZIN.]

PHLORONE. ($C_{18}H_{14}O_2$) A yellow oil obtained by the dry distillation of camphorate of lime. It emits an odour like peppermint.

PHOCENIC ACID. [VALERIANIC ACID.]

PHOCENIN. Synonymous with VALERIN.

PHŒNIX (*Φοῖνιξ*), one of the most renowned of the fabulous monsters of antiquity, defined by the Arabians to be a "creature whose name is known, its body unknown." (Richardson's 'Arabic and Persian Dict.') The earliest author who mentions it is Hesiod (ap Plut., 'De Defectu Orac.,' cap. 11; and ap. Plin., 'Hist. Nat.,' lib vii. cap. 49), who merely says that it lives nine times as long as a crow The first detailed description and history that we meet with is in Herodotus, whose words on that account deserve to be quoted at length. "There is also," says he, in his account of Egypt (lib. ii., cap. 73), "another sacred bird, the name of which is the phœnix; I have not myself seen it except in a picture, for it seldom visits them, only (as the people of Heliopolis say) every five hundred years. And they say that he only comes when his sire dies. And he is, if he is like his picture, of size and shape as follows: part of his plumage is gold-coloured, and part crimson; and he is for the most part very like to the eagle in outline and bulk. And this bird, they say, devises as follows, but they say what is to me beyond belief: that setting out from Arabia, he brings his sire to the temple of the sun; that he covers him with myrrh, and buries him in the temple of the sun; and that he covers him thus: first he forms an egg of myrrh as large as he is able to bear, and afterwards tries whether he can carry it; and when he has made the trial, upon this he hollows out the egg, and puts his sire into it, and covers with other myrrh that part of the egg where he had made the hole and put in his sire; and when his sire lies inside, the weight [of the egg] is the same [as it was before it was hollowed out], and having covered him up, he conveys him to Egypt into the temple of the sun. Such are the things which they say this bird performs." Such is the story as told in Herodotus, and it is substantially the same as what was afterwards, though with various embellishments, repeated and believed for more than a thousand years. It would be tedious and useless to quote the words of each author who forms the link in the chain: it will be sufficient to mention that between the times of Herodotus and Tacitus, the fable of the 'Phœnix' is told more or less fully and circumstantially by numerous classical writers. Of these writers perhaps the only passage curious enough to be particularly noticed is that in Lampridius, who tells us that Heliogabalus promised his guests a phœnix for supper; he was, however, obliged to be content with a dish of the tongues of phœnicopters (or flamingoes).

But it is not only in heathen authors that this fable is to be found; it is mentioned and believed by the Jewish rabbinical writers, and by the early fathers of the Christian church. The very words of several of these writers may be seen in Bochart (*loco cit.*); but the only rabbinical addition to the story worth noticing is preserved by Rabbi Osaia in his 'Berescith Rabba,' cap. 19 (ap. Bochart *loco cit.*), who says that the reason why the phœnix lives so long, and is in a manner exempt from death, is because it was the only animal that did not eat of the forbidden fruit in Paradise. A somewhat similar bird seems to have been known to the Arabians under the name of *Anka*. Mr. Lane, in the notes to his translation of the 'Tales of a Thousand and One Nights' (ch. 20, note 22), tells us, on the authority of Kaswini, that the anka is the greatest of birds; that it carries off the elephant as a kite carries off the mouse; that, in consequence of its carrying off a bride, God, at the prayer of a prophet named Handhalah, banished it to an island in the circumambient ocean, unvisited by men, under the equinoctial line; that it lives one thousand and seven hundred years; and that when the young anka has grown up, if it be a female, the old female bird burns herself; and if a male, the old male bird does so.

Many of the early fathers believed the story so firmly that they did not hesitate to bring it forward as a proof of the resurrection; and that, not as an *argumentum ad hominem*, when disputing with heathens, but seriously, and in writings addressed to converts to Christianity. St. Clement is the first who uses this argument (*loco cit.*), in which he is followed by St. Cyril and Tertullian (*locis cit.*), and Epiphanius ('Ancor.,' sec. 84, p. 89). The passage in St. Cyril (which also contains two or three additional embellishments) will serve as a specimen. "God knew men's unbelief," says he (in Mr. Church's translation, Oxford, 1838), "and provided for this purpose a bird called a phœnix. This bird, as Clement writes, and as many more relate, the only one of its race, going to the land of the Egyptians at revolutions of five hundred years, shows forth the resurrection; and this, not in desert places, lest the mystery which comes to pass should remain unknown, but in a notable city, that men might even handle what they disbelieve. For it makes itself a nest of frankincense and myrrh and other spices; and entering into this when its years are fulfilled, it evidently dies and moulders away. Then from the mouldering flesh of the dead a worm springs, and this worm, when grown large, is tranformed into a bird; and do not disbelieve this, for thou seest the offspring of bees also fashioned thus out of worms, and from eggs which are most moist thou hast seen the wings and bones and sinews of birds issue. Afterwards this phœnix, becoming fledged and a perfect phœnix, as was the former one, soars up into the air such as it had died, showing forth to men a most evident resurrection from the dead. The phœnix indeed is a wondrous bird, yet is irrational, nor sings psalms to God; it flies abroad through the sky, but it knows not the only-begotten Son of God. Is then a resurrection from the dead given unto this irrational creature, which knows not its maker; and to us, who ascribe glory to God and keep his commandments, shall there no resurrection be granted?"

Origen seems to doubt its truth ('Cont. Cels.,' lib. iv., cap. 98, p. 229), and Photius blames St. Clement for his credulity in mentioning it ('Biblioth.,' cod. 126, p. 305); but these two are (so far as the writer is aware) the only two of the ancient authors who did not believe it. This, however, ought not to lessen the authority of the fathers on other matters, nor should it be made a subject of reproach against them that "they were not proficients in a branch of knowledge which has been a peculiar study of modern times." (See Mr. Newman's preface to Mr. Church's 'Translation of St. Cyril,' Oxf., 1838.)

It would be almost impossible to enumerate all the more modern authors who, during the middle ages, expressed their belief in the existence of the phœnix, for the list would include almost all the writers on natural history, besides a great number of others. Perhaps the most curious circumstance relating to it is what is told us by Camden ('Britannia,' p. 783, ed. Lond., 1607), namely, that Pope Clement VIII. sent, in 1599, to Lord Tyrone, the chieftain of the Irish rebels, a phœnix's feather. This was mentioned in his work only eight years after the event took place, but we are not informed how the pope procured the feather, or what had become of it at the time when Camden wrote. Sir Thomas Browne, in his 'Vulgar Errors' (of which the first edition was published in 1646), thinks it necessary to state at some length his reasons for disbelieving the existence of the phœnix (book iii. ch. 12); and in 1552 he was attacked for this and other pieces of incredulity by Alexander Ross, in a work entitled 'Arcana Microcosmi, or the Hid Secrets of Man's Body discovered,' &c. With respect to the phœnix, the writer is not surprised at its seldom making its appearance, its instinct teaching it to keep out of the way of the tyrant of the creation—man; "for had Heliogabalus, that Roman glutton, met with him, he had devoured him, though there were no more in the world!" ('Arca. Micr.,' p. 202.) Alexander Ross, who was really a person of some sense and learning, was probably one of the last believers in the phœnix, which is now given up entirely to the poets; indeed, since the appearance of the 'Rejected Addresses,' almost abandoned even by them.

PHŒNIX, a southern constellation of Bayer, which may be best described as close to (but farther from the south pole than) the bright star in Eridanus (Achernar). Its principal stars are as follows:—

PHOSGENE GAS. [Chlorocarbonic Acid Gas.]

PHOSPHATES. [Phosphorus.]

PHOSPHIDES. [Phosphorus.]

PHOSPHITES. [Phosphorus.]

PHOSPHO-BERGAMIC ACID. [Bergamot, Essence of.]

PHOSPHO-GLYCERIC ACID. [Glycerin.]

PHOSPHORESCENCE. When phosphorus is exposed to the air it undergoes slow combustion, and emits a feeble light which is visible in the dark. Certain mineral substances emit a phosphorescent light when gently heated, such as phosphorite and chlorophane. The light however soon ceases and cannot be renewed until the body has been exposed to the sun, or to the electric flash produced by discharging a Leyden jar. Several kinds of sea fish become luminous soon after death, and the waters of the ocean frequently appear luminous from the presence of luminous animalculæ: this, however, is a subject which belongs to our Natural History Division—Luminosity of Organic Beings.

PHOSPHORIC ACID. [Phosphorus.]

PHOSPHORIC ACID, MEDICAL PROPERTIES OF. Dry phosphoric acid is sometimes used in the form of pills, but this is not an eligible mode; the common form is that of solution, constituting the dilute acid of the 'Pharmacopœia.' This differs from the other dilute mineral acids in not affecting so strongly the digestive organs, on which account it may be persevered in for a longer time. It is peculiarly suited to disordered states of the mucous surfaces, and also to states of debility, characterised by softening of the bones and a phosphatic condition of the urine. In this latter state it is often more efficacious when combined with iron, in the form of a phosphate of that metal; or better, the pyrophosphate. The same combination is of great utility in most cases of diabetes. In passive hemorrhages, phosphoric acid, properly diluted, quickly arrests the bleeding, as it coagulates the blood. This property is possessed in a stronger degree by the undiluted acid; and hence if injected into a vein, causes death. A poisonous dose of the strong acid may be counteracted by chalk, or carbonate of soda.

PHOSPHOROUS ACID. [Phosphorus.]

PHOSPHOVINIC ACID, *Ethyl-phosphoric acid.* [Ethyl.]

PHOSPHORUS. This elementary, solid, non-metallic body was discovered in 1669, by Brandt, an alchemist of Hamburg; he kept the mode of preparation for a long time secret, but as he could not conceal the fact of its being obtained from urine, Kunkel tried to procure it from the same source, and he succeeded in the attempt.

It will not be requisite to describe the original mode of preparing this very peculiar substance; therefore we shall only give an outline of the method at present employed. It has been shown that animal bone [Bone, in Nat. Hist. Div.] contains a large quantity of phosphoric acid combined with lime, forming a phosphate of that earth. It was first proposed by Scheele to obtain phosphorus from bones. For this purpose the bones are ignited or calcined in contact with air till they become white; when this happens it is a proof that the charcoal derived from the decomposition of the animal matter is entirely burnt off. In this state they consist of phosphate of lime mixed with little else than a small portion of carbonate of lime. After being reduced to a fine powder, they are mixed with sufficient water to form a thin paste, and digested for a day or two with two-thirds their weight of sulphuric acid. In this case sulphate of lime is formed, and the greater part of it remains insoluble, and a superphosphate of lime remains in solution; this is to be evaporated, and the precipitate formed being separated, the clear fluid, which is chiefly phosphoric acid, is to be evaporated nearly to dryness, and mixed with about a fourth of its weight of powdered charcoal; this mixture is to be strongly heated in an earthen retort, the beak of which is immersed in water; by the action of the heat the phosphoric acid yields oxygen to the carbon, and the results are carbonic acid or oxide, which is evolved in the gaseous state, and the vapour of phosphorus, which is condensed by passing into water.

The crude phosphorus thus obtained is mixed with wet sand and purified by redistillation from a large cast-iron retort, the neck of which just dips below the surface of water contained in a flat earthenware pan. The phosphorus is from time to time removed by an iron ladle and cast into sticks by fusing under warm water in a vessel that has a long glass tube attached to its lower part by a stopcock. The tube is surrounded by cold water contained in a tub, and at first its end is closed by a cork. On opening the tap the melted phosphorus flows into the glass tube, and when it has solidified, the cork is carefully withdrawn, and with it the rod of phosphorus, fresh liquid phosphorus continuing to flow in. By this means the whole of the phosphorus may be drawn out in one continuous stick of any required diameter, and coiled round in the tub or cut into pieces with scissors while still under water.

Phosphorus is solid, translucent, and nearly colourless; it is so soft that it may be indented by the nail, and it is very readily cut. When heated to 111·5° Fahr. it fuses, and at 550° is converted into vapour; it has a peculiar smell when exposed to the air, but this is probably derived from the action of the oxygen of the air upon it. Neither water nor alcohol dissolves phosphorus, but it is slightly dissolved by ether and by oils. It emits light when exposed to the air in the dark, and hence its name (from *φῶς, light,* and *φέρειν, to carry*). It is extremely inflammable, and has been known to take fire spontaneously in the atmosphere when the temperature was not above 60° Fahr. Its specific gravity is about 1·83. Phosphorus is also soluble by the aid of heat in naphtha, bisulphide of carbon, and dichloride of sulphur; on cooling from solution in the last-mentioned it has been obtained in dodecahedral crystals, and by mere fusion and slow cooling of a larger quantity, it has been procured in octohedral crystals.

Phosphorus may be *granulated* by fusing under alcohol, or in water containing a little urea, and well agitating till cold.

Amorphous, or *red Phosphorus* is an allotropic variety that has long been known to chemists, but has been extensively manufactured only since the year 1848. It is most easily made by keeping ordinary phosphorus for several days at a temperature of 450° or 460° Fahr. It forms a red or purple friable amorphous mass. Its specific gravity melting point and igniting point are higher than ordinary phosphorus. It is insoluble in bisulphide of carbon, is neither dangerously inflammable nor poisonous, and does not communicate to the workpeople engaged in handling it, that painful disease of the jaws that ordinary phosphorus imparts. These properties have secured for it extensive use in the manufacture of lucifer matches, and it was at one time hoped that it would quite supersede the white variety: unfortunately however, it gradually attracts oxygen from the air and the phosphorous and phosphoric acids produced are so exceedingly deliquescent that matches prepared with amorphous phosphorus are liable to become damp.

Black Phosphorus is another amorphous variety of this element. It is obtained by very suddenly cooling melted phosphorus.

The equivalent of phosphorus is 32.

Oxygen and Phosphorus combine with great readiness, and form four distinct compounds, namely :

1. Oxide of phosphorus	P_2O
2. Hypophosphorous acid	PO
3. Phosphorous acid	PO_3
4. Phosphoric acid	PO_5

1. *Oxide of Phosphorus.*—This is prepared by melting phosphorus in hot water, and in this state forcing a jet of oxygen gas upon it. The phosphorus burns under water, and the results are phosphoric acid, which remains in solution, and which we shall presently describe, and a red pulverulent body, which remains at the bottom of the vessel, and is the oxide of phosphorus. It is inodorous and tasteless, and is insoluble in water, alcohol, ether, or oil. It undergoes no change in the air, even when heated to above 600° Fahr.; but at a low red heat it burns. In chlorine gas it inflames. It decomposes nitric acid readily, and combining with its oxygen, becomes phosphoric acid. It does not possess either acid or alkaline properties.

2. *Hypophosphorous Acid* was discovered in 1816 by M. Dulong. When phosphide of barium is acted upon by water, both suffer decomposition, and there are formed phosphuretted hydrogen, phosphoric acid, hypophosphorous acid, and baryta; the earth combines with both the acids, and the phosphate of baryta being insoluble, is precipitated, while the hypophosphite is soluble, and sulphuric acid being added to the solution, sulphate of baryta is precipitated, and free hypophosphorous acid remains in solution; by evaporating this, a viscid strongly acid substance is obtained, which is hydrated hypophosphorous acid.

Hypophosphorous acid is liquid, uncrystallisable, has a powerful taste, is heavier than water, and cannot be obtained in a dry state. When subjected to the action of heat, it is quickly decomposed into phosphuretted hydrogen gas, which escapes, and phosphorous and phosphoric acids. Water dissolves this acid in all proportions; it acts very powerfully as a deoxidising agent, but nevertheless combines with many salifiable bases, forming salts which are termed *hypophosphites*; these salts are remarkably soluble in water; they are usually deliquescent, and crystallise with great difficulty. From the circumstance that neither this acid nor its salts can be obtained free from water, its true formula is probably PH_2O_3, that is phosphoric acid in which two atoms of oxygen are replaced by two of hydrogen.

3. *Phosphorous Acid*, like the preceding, is entirely an artificial product; it is obtained in the greatest purity by subliming phosphorus through bichloride of mercury in a glass tube. During the action of the heat, the phosphorus takes half the chlorine from the mercury, and they form a volatile compound which condenses into limpid liquid chloride of phosphorus: when this is mixed with water, mutual decomposition occurs; the hydrogen of the water and the chlorine of the chloride form hydrochloric acid, while the oxygen and phosphorus unite to form phosphorous acid. By evaporation the hydrochloric acid is expelled, and when evaporation has been continued until the residue, while hot, has the consistence of a syrup, it becomes a solid crystalline mass on cooling, which is hydrated phosphorous acid. This acid dissolves very readily in water, has a sour taste, reddens vegetable blue colours, and combines with some bases to form salts, which are called *phosphites*.

Phosphorous acid is also formed when phosphorus is burnt in rarefied air. When phosphorus is exposed to air and moisture, it has been long known that a dense sour fluid is formed by the absorption of oxygen: this was supposed by M. Dulong to be a peculiar acid, and he called it phosphatic acid; it was however subsequently shown by Davy to be a mixture of phosphorous and phosphoric acids.

Phosphite of Ammonia is procured by adding carbonate of ammonia to the acid to saturation. It crystallises in deliquescent needles; when heated, it is decomposed, giving out ammonia; and by the continued application of heat, the phosphorous acid remaining is converted into phosphoric acid. It is not a salt of any importance.

4. *Phosphoric Acid.*—This acid exists largely in nature, not only, as has been already mentioned, in combination with lime, forming bone, but also in some vegetable products, and often in the bowels of the earth, combined with lime, forming a mineral which, when crystallised, is frequently called *apatite*. [See also PHOSPHATITE, in NAT. HIST. DIV.] It also occurs in combination with oxide of iron, copper, lead, manganese, and uranium; but the quantity of these compounds is by no means large, and they are regarded chiefly as objects of curiosity.

Phosphoric Acid may be artificially formed by the direct combination of its elements. When a piece of phosphorus is inflamed, and immediately covered by a large bell glass, white flakes of phosphoric acid are produced, which fall like snow in the vessel. When exposed for a short time to the air, the acid deliquesces. So great is its affinity for water, that when collected, and a little water added to it, it is converted into a hydrate with explosive ebullition, owing to the heat which is evolved during combination. Phosphoric acid, when free from water, may be volatilised in a glass tube by the heat of a spirit-flame; the hydrate is even more readily dissipated.

Phosphoric acid is also formed when phosphorus is heated in moderately strong nitric acid; the nitric acid is decomposed, and yields oxygen to form the phosphoric acid. By evaporation in a platina capsule, hydrated phosphoric acid is obtained.

Phosphoric acid is colourless, inodorous, dense, extremely sour to the taste, and acts strongly on vegetable blue colours; it does not, however, like sulphuric acid, destroy the skin when applied to it. Phosphoric acid is peculiarly disposed to combine with different proportions of water, and these compounds exhibit properties so different, that they might be supposed to be three different acids, instead of different hydrates of the same acid. When the dry acid, obtained as described from the combustion of phosphorus, is thrown into water, a mixture of the three hydrates is obtained in variable proportions; but they may be separately obtained in a pure state from the common phosphate of soda of the shops, after it has been purified by solution and recrystallisation. Decompose a warm solution of this salt by means of a solution of acetate of lead, and wash the precipitated phosphate of lead, and then pass a current of hydrosulphuric acid through it while suspended in water. When the excess of hydrosulphuric acid has been expelled by heat, a very sour fluid remains, which is a *terhydrate of phosphoric acid* ($3HO, PO_5$).

This terhydrated acid is unalterable by boiling its solution or keeping it for any length of time. The class of salts which it forms are *phosphates*, which give a yellow precipitate with nitrate of silver ($3AgO, PO_5$). Common phosphate of soda contains, therefore, this terhydrated phosphoric acid.

Pyrophosphoric Acid.—Professor Clark, of Aberdeen, first discovered that when common phosphate of soda is heated to redness, it is completely changed in some of its properties, and after being dissolved in water, it affords crystals of a new salt, which he named *pyrophosphate of soda* ($2NaO, PO_5$). It gives a white precipitate with nitrate of silver ($2AgO, PO_5$), instead of a yellow one. If a solution of this salt be decomposed by one of acetate of lead, and the precipitated phosphate of lead be treated with hydrosulphuric acid as already described, and then evaporated in vacuo, over sulphuric acid, without the application of heat, the remaining solution is pyrophosphoric acid, consisting of $2HO, PO_5$.

Metaphosphoric Acid.—If equivalent proportions of ordinary phosphate of soda ($2NaO, HO, PO_5$) and terhydrated phosphoric acid ($3HO, PO_5$) be evaporated to dryness, a tribasic phosphate of soda is obtained, containing ($NaO, 2HO, PO_5$), and this, on being treated as the last, gives an acid liquor, containing the metaphosphoric or monohydrated phosphoric acid (HO, PO_5).

Glacial phosphoric acid is also in general mostly metaphosphoric acid. This hydrate is characterised by producing a white precipitate in solution of albumen, and in solutions of the salts of earths and metallic oxides; precipitates which are remarkable semifluid bodies, or soft solids without crystallisation.

Hydrogen and Phosphorus combine in three different proportions. When phosphide of calcium is thrown into hot water containing hydrochloric acid, a yellow powder precipitates, which is a solid phosphide of hydrogen, containing P_2H.

Phosphuretted Hydrogen Gas (PH_3).—This gas was obtained by Gengembre in 1783: it is procured by boiling phosphorus in a solution of potash, or in small quantity on bringing phosphide of calcium into contact with water. The gas which arises is spontaneously inflammable; and during its combustion there are formed water and phosphoric acid: it is colourless, and has a disagreeable odour resembling that of onions. Water dissolves about two per cent. of this gas; but the solution, unlike that of sulphuretted hydrogen gas, has no acid properties. It deposits solid phosphuretted hydrogen when exposed to light. The specific gravity of this gas, according to Dumas, is 1·761. Its spontaneously inflammable property is due to the presence of *liquid phosphuretted hydrogen* (PH_2). The latter may be separated by passing the freshly-made gas through a tube immersed in a freezing mixture. It burns explosively when exposed to the air, and renders hydrogen, carbonic oxide, &c., spontaneously inflammable.

Phosphuretted hydrogen gas decomposes some metallic solutions, such as those of copper and mercury, and metallic phosphides are precipitated. When it is pure, it is entirely absorbed by sulphate of copper and chloride of lime.

Chlorine and Phosphorus combine in two proportions, forming the pentachloride and terchloride.

Terchloride of Phosphorus (PCl_3).—When a mixture of bichloride of mercury and phosphorus is heated, we have already had occasion to notice that terchloride of phosphorus is produced. When first procured, it has generally a reddish colour, owing to the presence of a little uncombined phosphorus. When this has had time to deposit, or when it is purified by slow distillation, it becomes limpid and colourless. It has a suffocating odour, and fumes when exposed to the air. Its specific gravity is 1·616. It does not alter the colour of dry litmus-paper; but if moist, then hydrochloric and phosphorous acids are formed, which redden it strongly. The vapour of this compound is combustible, and acts with great energy upon water, producing the changes which have been described.

Pentachloride of Phosphorus (PCl_5) is obtained by the spontaneous combustion of phosphorus in chlorine gas; a white, flaky, volatile compound is formed, which is the perchloride. It is volatile, rising in vapour at 200°. It is fusible under pressure, and crystallises in prisms. It reddens dry litmus-paper, owing, as has been suspected, to its acquiring oxygen and hydrogen from the decomposition of the paper. Like the protochloride, it acts strongly upon and decomposes water; but the results are hydrochloric acid and phosphoric, instead of phosphorous, acid.

Phosphide of Nitrogen (PN_2?).—This compound cannot be obtained by direct action; it is the result of the action of ammonia on the chlorides of phosphorus. The changes which occur are effected with difficulty, but the phosphide of nitrogen eventually obtained has the following properties:—It is a light white powder, and, although formed of very volatile constituents, it remains fixed and infusible even at a red heat, when the access of air is prevented; but if that be present, white vapours of phosphoric acid are formed. This compound is remarkable, also, for its indifference even to the most powerful re-agents; it is insoluble in water and in acids, nitric acid even attacking it only after long continued exposure to it. Chlorine and sulphur do not act upon it; it is insoluble in alkaline solutions, but when heated with solid hydrate of potash, ammonia is evolved. According to Gerhardt, it contains hydrogen, and its formula is HN_2P.

Sulphur and Phosphorus may be made to combine in all proportions by fusion in an exhausted flask or under water; but the operation requires great caution. The resulting sulphides are very inflammable, and mostly crystalline.

Phosphorus and Iodine. [Iodine.]

Phosphorus and Bromine. [Bromine.]

Phosphorus may be made to combine with the greater number of the metals; the most important of these compounds (*phosphides*) will be found under each particular metal.

Detection of Phosphorus.—Phosphorus is very poisonous. It is readily detected in a mixture containing organic matter by placing the suspected mixture in a flask, adding sulphuric acid, suspending a piece of paper streaked with solution of nitrate of silver from the upper part of the flask, and gently heating; if phosphorus be present, the paper will exhibit black marks of phosphide of silver. The absence of sulphuretted hydrogen, and of arsenic, must be previously ascertained; the one by acetate of lead paper suspended in the flask, the other by Marsh's test.

Detection and Estimation of Phosphoric Acid.—One of the best tests for phosphoric acid is the production of a white crystalline precipitate in the presence of ammonia, on the addition of a soluble salt of magnesia. The resulting ammonio-phosphate of magnesia, on being ignited, is converted into phosphate of magnesia, which contains 63·33 per cent. of phosphoric acid.

PHO'SPHORUS, MEDICAL PROPERTIES OF. This elementary substance exists as an essential constituent both of vegetable and animal bodies; yet when applied in a concentrated and pure state to any organised structure, it acts upon it as a violent and corrosive poison. Into animal bodies it is introduced in a diluted and combined state, by which it is disarmed of its virulence, as an ingredient of many common articles of food. One of the chief sources of it is the starch of the cereal grains, such as wheat-flour, in the ashes of which, when burnt, it amounts to 23 per cent. (Prout's 'Bridgewater Treatise,' book iii.); also alliaceous plants, such as onions, in which it exists as a phosphate of iron; polygonous and other plants, in which it occurs as a phosphate of lime. It also exists not only in the bones and other hard parts of animals, but in many of the fluids, especially the excretions. Thus it is found in the milts and roes of fishes, the substance of oysters, the yelk of eggs, in the liver, and also the brain, in which organ of the human being it amounts to from 2 to 2¼ per cent.

Phosphorus is of all stimulants the most powerful and diffusible, but, on account of its activity, highly dangerous. Its poisonous action seems to be connected with its strong affinity for oxygen, by which it is converted into phosphorous and phosphoric acids. Hence when brought into contact with the animal tissues, it abstracts oxygen from them, and produces an eschar, resembling a burn: the phosphorus in this way loses weight and is absorbed, so that the exhalation from the lungs and the cutaneous perspiration are impregnated with the vapour, and, under certain circumstances, luminous. A very small quantity of solid phosphorus, even one grain and a half, has proved fatal. Solutions of phosphorus in oils, fixed or volatile, or in ethers, are still more active and dangerous. The vapour of phosphorus is accused of causing a peculiar affection of the jaw-bone in persons working much with it, such as manufacturers of congreve matches. This evil may be prevented by wearing a sponge before the mouth and nostrils, and the observance of great cleanliness, especially using a solution of soda for washing the hands. Acetate of potash is useful in the dysuria which follows poisoning by phosphorus.

Little use is made of phosphorus or its oleaginous solutions in medical practice in Great Britain, though in cases of extreme prostration of the nervous system it is not without its value.

In the event of a poisonous dose being taken, bland mucilaginous, not oily, fluids should be freely administered, followed by magnesia or chalk in boiled water.

PHOSPHURETTED HYDROGEN. [Phosphorus.]

PHOTOGRAPHY is both an *art* and a *science*. As an art it enables us to draw, depict, or write by means of light. As a science it teaches us how to observe and to investigate the effects produced by light upon all natural bodies, whether animate or inanimate, mineral, vegetable, or animal. Its study as an art is of comparatively recent date, but the science had previously excited the attention of nearly all the most eminent investigators in modern science. The names of Davy, Wedgwood, Thomas Young, Wollaston, and the two Herschels in this country—of Scheele, Ritter, Seebeck, Berthollet, and Becquerel on the Continent—testify to this effect. Photography is worthy of special attention from the fact that it requires for its rational and thoroughly successful pursuit a knowledge of chemistry, optics, and physics generally, together with an amount of artistic taste and manual dexterity, such as must be useful not only for purposes of mental training, but under a variety of circumstances in actual life. The variety of its parts and aims gives it a special charm for those who like to have a pursuit admitting of both activity of mind and body; its processes are as much carried on out of doors as in close laboratories. Further it has this charm, that while it furnishes problems of the greatest interest and intricacy for the most advanced philosopher in optics or chemistry, it has its practical processes, which may be readily apprehended, and exercised for purposes of utility or recreation by those who are but little skilled in physical manipulations.

The history of photography has been so fully treated of by Mr. Robert Hunt, in his 'Researches on Light,' and in his 'Treatise on Photography,' and also by the Abbé Moigno, in his 'Repertoire d'Optique Moderne,' that we need not do here more than recapitulate in a brief manner the points of chief interest which they have given at greater length.

It may be well to say at the outset, that it was not till the year 1839 that Photography acquired for itself distinct recognition, through the investigations of Fox Talbot and Daguerre, which resulted in the introduction of the two processes known as the Calotype or Talbotype, and Daguerreotype. As usual in the history of art and science, approximations had been attained to by earlier experimentalists. It is interesting to inquire into the labours of some of these. Proceeding historically, we shall find that observations relating to the *science* of photography precede the first attempts at establishing the principles of the art.

In 1722 Petit noticed that solutions of nitrate of potash and muriate of ammonia crystallised more readily in the light than they did in darkness. In 1777 Scheele wrote, "It is well known that the solution of silver in acid of nitre, poured on a piece of chalk and exposed to the beams of the sun, grows black. The light of the sun reflected from a white wall has the same effect, but more slowly, heat without light being without effect." Again, "Fix a glass prism at the window, and let the refracted sunbeams fall on the floor. In this coloured light put a paper strewed with *luna cornua* (chloride of silver), and you will observe that this *horn silver* grows sooner black in the violet ray than in any of the other rays."

Senebier repeated these experiments, and also experimented on the influence of light in the bleaching of wax.

In 1798 Count Rumford sent to the 'Philosophical Transactions' a memoir entitled 'An Inquiry concerning the Chemical Properties that have been attributed to Light.' In this paper the Count attempts to prove that all the effects produced upon metallic solutions by bright sunshine are due to heat. In 1802 Mr. Harrup refuted this view, and showed that several salts of mercury were reduced by light alone, and not by heat.

In 1801 Ritter proved the existence of rays in the solar spectrum, which are to be found beyond its visible limits, and that these rays have the power of darkening chloride of silver. These researches having excited attention, MM. Berard, Seebeck, Berthollet, Sir W. Herschel, Sir H. Englefield, Wollaston, Davy, and others, made various experiments which tended still further to confirm the proof that light had a special influence over bodies beyond that exercised through its heat; and that the colour of the light was in some way related to this newly observed action of the sunbeam.

Before proceeding to notice the early efforts of those who laid the foundation of the *art* of photography, with which we are now to be chiefly engaged, we may observe that Priestley, Senebier, Ingenhousz, De Candolle, Saussure, and Ritter, directed attention to the influence of light upon plants—an interesting and important subject. Others followed in a similar track, still, however, leaving the matter in a comparatively obscure condition. The action of light on the human frame, and on animal life generally, has not yet been fairly investigated. That some special action will be detected there can be no doubt. We have long thought that light will come to be considered as important an element to health as fresh air and wholesome food. It may possibly be that much mental or bodily labour, exercised in the absence of the stimulus of daylight, is indirectly injurious to animal life.

But let us proceed to trace rapidly the *art* of photography to its source. In the Journals of the Royal Institution of Great Britain for 1802 will be found a paper by "Thomas Wedgwood and Humphry Davy"—the first a brother of the famous porcelain manufacturer, the second the Sir Humphry Davy of a later period. Their joint paper was entitled 'An Account of a Method of Copying Paintings upon Glass and of making Profiles by the Agency of Light upon

Nitrate of Silver; with Observations by H. Davy.' This paper contains the complete germs of the photographic art, namely, the application of an optical instrument to imprint upon a sensitive chemical surface the images of all natural objects illuminated by the sunbeam, or other source of light. The instruments used by these observers were the camera obscura and the solar microscope: but let us first see how this important invention took shape in the mind of Wedgwood.

According to Davy, Wedgwood first commenced his researches with a view to copy the images of the camera obscura; and for this purpose, says Davy, "he first used nitrate of silver, which was mentioned to him by a friend as a substance very sensible to the influence of light." This nitrate of silver was applied in solution to surfaces of white paper and leather. "White paper or white leather," to quote the words of the memoir of 1802, "moistened with solution of nitrate of silver, undergoes no change when kept in a dark place; but on being exposed to the daylight, it speedily changes colour, and, after passing through different shades of grey and brown, becomes at length nearly black. The alterations of colour take place more speedily in proportion as the light is more intense. In the direct beam of the sun two or three minutes are sufficient to produce the full effect; in the shade several hours are required; and light transmitted through different-coloured glasses acts upon it with different degrees of intensity." . . . . "When the shadow of any figure is thrown upon the prepared surface, the part concealed by it remains white, and the other parts speedily become dark. For copying paintings on glass the solution should be applied on leather, and in this case it is more readily acted on than when paper is used. After the colour has been once fixed on the leather or paper, it cannot be removed by the application of water, or water and soap; and it is in a high degree permanent. The copy of a painting, or the profile, immediately after being taken must be kept in an obscure place; it may, indeed, be examined in the shade, but in this case the exposure should be only for a few minutes: by the light of candles or lamps, as commonly employed, it is not sensibly affected." No means were found to fix permanently the impressions thus produced. And, as regards the primary end of Wedgwood's researches, we are told that "The images formed by means of a camera obscura have been found to be too faint to produce in any moderate time an effect upon the nitrate of silver." Davy adds, "In following these processes, I have found that the images of small objects produced by means of the solar microscope, may be copied without difficulty on prepared paper. This will probably be a useful application of the method; that it may be employed successfully, however, it is necessary that the paper be placed at but a small distance from the lens."

The muriate (chloride) of silver was found to be more sensitive to light than the nitrate. "Even in the twilight, the colour of the moist muriate of silver spread upon paper slowly changed from white to faint violet; though under similar circumstances no immediate alteration was produced upon the nitrate." Davy concludes with these remarkable words: "Nothing but a method of preventing the unshaded parts of the delineations from being coloured by exposure to the day, is wanting to render this process as useful as it is elegant."

From this time the art in England slumbered until 1834, when Mr. Fox Talbot, without knowing what had been done, commenced experiments with the same end in view.

But we must now turn to a neighbouring country, France. In 1813, M. Niépce, of Chalons on the Saone, was engaged in a task identical in conception with that of Wedgwood. He was endeavouring, by means of bituminous varnishes and metal plates, to fix permanently the images of the camera, and he succeeded to a remarkable extent. His experiments were carried on until 1827, in which year he presented a memoir with specimens to the Royal Society of London; but, as he kept his processes secret, no notice was taken of his labours. Niépce returned to France dispirited. He there, however, continued his experiments, making pictures on a surface of bitumen laid upon a metal plate, which he afterwards engraved by ordinary engraver's acid. The rationale of his process is this:—Light is capable of hardening a bituminous surface in such a way that the usual solvents of bitumen no longer act readily upon the altered part of the surface, and therefore only the shaded portions of a partially illuminated plate would yield to such solvents as the mineral naphthas, for example, furnish. But when a metal plate had been partially laid bare by the removal of the bitumen in the shadows, nothing was easier than to etch such a plate by aqua fortis, and this was what Niépce did. A plate thus made and prints from it were in the possession of the late Mr. Robert Brown, of the British Museum. It is to be hoped that they are placed in the Museum itself. M. Niépce named his art *Heliography.*

In 1829 M. Niépce became acquainted with a M. Daguerre [DAGUERRE, L. J. M., in BIOG. DIV.], who was noted for his dioramic paintings, and who was, it is alleged, also engaged upon methods for fixing the images of the camera. A deed of partnership was executed between the two experimentalists, and they jointly pursued their labours until the death of Niépce, in July, 1833. A new arrangement was then made between his son, M. Isidore Niépce and Daguerre.

At length came the memorable year 1839, when the whole scientific and artistic world was startled at the announcement that objects could be made to draw their own pictures with an accuracy and minuteness quite unattainable by hand. In January, 1839, the first specimens by Daguerre were shown, but the process was withheld until the month of July. This enabled Mr. Fox Talbot to secure to himself the merit of priority of publication of a method by which sun-drawn pictures could be successfully produced. He, on the 13th of January, communicated to the Royal Society a paper, entitled 'Some Account of the Art of Photogenic Drawing, or the Process by which Natural Objects may be made to delineate themselves without the Aid of the Artist's Pencil.' And on the 21st of February in the same year, he gave another communication on the method of preparing sensitive paper and of fixing the images obtained. That the two experimentalists, Talbot and Daguerre, were independent discoverers is evident from the dissimilarity of their processes; the light and camera obscura being the only means strictly in common.

Mr. Talbot's method consisted in washing letter-paper over repeatedly with alternate solutions of salt and nitrate of silver; at a certain stage a surface was obtained which gave images under the influence of the camera, and these images were fixed by immersion in a strong solution of salt and water, in which the unaltered parts of the chloride of silver were soluble. This process was not very sensitive, and was therefore set aside by Mr. Talbot's later discoveries of 1840.

Let us now examine the nature of Daguerre's process called the Daguerreotype. A plate of silvered copper is highly polished, and then exposed to the vapour of the chemical element iodine, which imparts to the plate a series of colours, depending on the quantity of iodine absorbed. The exposure to the vapour was carried on until the plate assumed a rosy tint, or simply a deep orange-yellow, bordering on red. The plate was now sensitive, and had only to be exposed at the focus of the camera obscura in order to obtain a picture of any strongly illuminated object. Some minutes were necessary even in full sunshine. The plate was then withdrawn into the darkened room in which it had been prepared, and there it was exposed to the vapour of heated mercury, which has the wonderful property of attaching itself only to those parts of the iodised plate which have been exposed to light; and this deposit takes place in proportion to the original intensity of light of the image. Thus a picture was produced which represented in shades of black and white the original optical image seen on the ground-glass screen of the camera.

A solution of the hyposulphite of soda was used to fix the image by removing the compound of iodine and silver which still veiled in some degree the shadows on the plate. Subsequently M. Fizeau improved the appearance of Daguerreotypes by imparting to them a warm tinge by a thin film of gold which was thrown down upon the image by a spontaneous electro-chemical action.

The original Daguerreotype process was not sufficiently sensitive to be used in portraiture. To Mr. Goddard, who deserves reward, we owe the great improvement of the introduction of a second chemical agent, which now enables us to make pictures in a second of time. In 1840 Mr. Goddard combined bromine with iodine, and at once published the result in the 'Athenæum' journal. In the dull weather of November of that year, he obtained portraits in a few seconds; Daguerre's process requiring many minutes, even in a strong light. Mr. Claudet, at a later date, used chlorine with iodine for a similar end; but the bromine is still used in preference.

One of the best modes of procedure now adopted is the following:—Take a plate of silvered copper and polish it by means of tripoli powder and oil of lavender or rosemary, applied by cotton velvet, finishing the polish by *clean* cotton velvet alone. Then expose the silver to a mixture of iodine and pure sand in such a manner that the vapour of the iodine shall act equally upon the surface of the silver plate, to which it imparts a coating which is seen to be coloured when examined by light reflected from any white surface, a piece of paper for example. As soon as the plate has assumed an orange-yellow colour it is removed, and then exposed to the vapour issuing from a peculiar red compound of bromine with lime, called "bromide of lime." Over this it absorbs bromine, and assumes a rose tint; and as soon as this shade of colour has been obtained, the plate must be removed and again exposed to the iodine vessel until the rose colour has deepened into a plum tint. The plate is then ready for exposure in the camera obscura. No time can be stated for these various exposures, as temperature influences the results. A few seconds in each case suffice. The plate must be prepared in a room which can be darkened, the light of a candle, or that obtained through yellow glass, being alone used at the last iodising, and in some of the subsequent operations. After exposure in the camera, the plate is exposed to the vapour of mercury for a few minutes, the mercury being at a temperature of about 180° Fahr. Here the picture is developed by the action of the mercury upon the bromo-iodised surface, the mercury being, it is believed by some, deposited upon the plate in proportion to the amount of light which fell upon its surface during its exposure in the camera. On its removal from the mercury box the plate is partially fixed by washing its surface with a strong solution of hyposulphate of soda. The final fixation is effected by boiling upon the plate a solution of a double salt, called hyposulphite of soda and gold. The image is now fixed upon the plate, and may be coloured by brushing over it colours in very fine powder. The image should be kept so as to exclude the vapours of an impure atmosphere, such as is usually found in large towns. Sulphuretted vapours will at once darken the light part of the image. The film of stain may, however, generally be removed by a solution of cyanide of potassium. The Daguerreotype is still unsurpassed in delicacy of detail.

Having given an account of the Daguerreotype, we might proceed to relate the history of Mr. Fox Talbot's researches, which led to the invention of the first successful process in photography on paper; but as these will be found detailed in Mr. Talbot's work 'The Pencil of Nature,' and in the specifications of his patents, we prefer to pass at once to consider a process which has now almost superseded all others, and which certainly sprang out of Mr. Fox Talbot's discoveries. Mr. Talbot used iodide of silver with nitrate of silver in excess, upon paper, for the purpose of procuring an image which remained latent until developed by a solution of gallic acid. The process now used, and called the Collodion process, of Mr. Scott Archer, consists in the use of a film, on glass, of collodion, containing also iodide of silver with an excess of nitrate, the development being accomplished by pyro-gallic acid, or by sulphate of iron, the use of which we owe to Mr. R. Hunt, in the place of gallic acid. The analogy is complete, but the latter materials give a greater delicacy of result.

Collodion is made by dissolving in ether and alcohol cotton-wool which has been altered in its properties by treatment with strong acids. The following is a good mode of proceeding, and is due mainly to the researches of Mr. Hadow.* Take of pure nitrate of potash in fine powder 510 grains, of oil of vitriol (specific gravity 1·833 about) 15½ drachms, of water 1½ drachm; stir together, and when at a temperature of from 150° to 155° Fahr. add, bit by bit, 15 grains of cotton-wool to each ounce of the acid mixture. Allow the cotton to soak for four or five minutes, and then wash it many times in water until it is quite free from acid. Then, to make the collodion, take 9 grains of the dry cotton, and add 6 drachms of pure ether (sp. gr. ·725 to ·730), and 2 drachms of pure alcohol (sp. gr. ·818 to ·820). The cotton should at once dissolve. In another bottle prepare what is called the "iodising solution," by taking alcohol (sp. gr. ·818 to ·820) one ounce, iodide of potassium 12 grains, iodide of cadmium 4 grains; dissolve the salts in the alcohol, and keep the solution for use. To make "iodised collodion," mix 6 drachms of collodion with 2 drachms of the iodising solution; this mixture changes by keeping, and should therefore be made only in moderate quantities. Having prepared the iodised collodion, a plate of glass is covered with it by pouring a quantity on the centre of the plate, and then allowing the liquid to flow to the corners in such a way that the glass shall be uniformly covered; the excess is then run off at one corner into a bottle set apart for the purpose. After a few seconds the film of iodised collodion is sufficiently firm to be fit for immersion (in the dark) in what is called the "nitrate bath." This bath is made by dissolving 30 grains of nitrate of silver in one ounce of distilled water. The nitrate of silver should be pure, and free from excess of nitric acid, and it should be saturated, when in solution, with iodide of silver: a little acetic acid, too, may be added. The plate is immersed in this bath for a few minutes, drained, and then exposed in the camera obscura. To develope the image, a solution of pyrogallic acid containing one grain of the salt to one ounce of water acidulated by 20 drops, or minims, of glacial acetic acid is poured upon the plate. If the image is not intense enough, a little weak solution of nitrate of silver must be added. The image obtained is fixed by a strong solution of hyposulphite of soda, in which it is immersed; or, instead, a weak solution of cyanide of potassium may be poured upon the plate, and left there until the yellow film of iodide of silver disappears. The plate is then washed and dried, and protected by a film of varnish, a spirit varnish being usually preferred for this purpose.

The picture thus obtained is, as in the calotype or Talbotype process of Mr. Fox Talbot, a *negative* one—that is to say, a picture having its light and shade reversed; though by modifying the collodion process *direct* positives may be at once obtained: a good negative, however, is a more valuable acquisition. In order to obtain copies correct in light and shade and position, a *positive* has to be made. There are many processes by which this can be done; but we will here give only one, which answers perfectly. Take the white of a fresh egg and beat up with every fluid ounce of it 12 grains of common salt: remove the froth thus obtained, and continue beating until all has become froth. Leave this froth to itself, and the greater part of the white of egg will become again liquid. Pour this liquid into a flat shallow dish, and upon it place carefully, so as to exclude bubbles of air, a sheet of thin paper (French paper is usually chosen); leave the paper for two or three minutes floating, so as to coat only one side with the "salted albumen," as the white of egg mixture is now called. Then carefully remove the sheet, and pin it up by a corner to dry. This operation can be carried on in daylight. To make this paper sensitive, it is floated upon a solution of nitrate of silver containing 100 grains of nitrate to one ounce of water. Here it is left for a minute, and then removed and suspended to dry. This last operation must be performed in a room lighted by yellow light, as in the case of the daguerreotype and collodion final preparation. Upon the dry paper the negative picture is placed face to face, and the whole exposed in a proper 'pressure-frame' to the sun or to daylight, or to the electric light for ten minutes or a quarter of an hour by night. After a few minutes the picture is found printed, and must next be fixed by immersion in a solution of hyposulphite of soda, one part of the salt in four parts of water. Ten or fifteen minutes' immersion would suffice to fix the picture; but in order to produce an agreeable tint of colour, a longer immersion is had recourse to, with the addition to the "fixing bath" of a few grains of a neutral solution of chloride of gold. After several hours' immersion in this bath, the picture is removed, and washed repeatedly with plenty of water; hot distilled water being used at last. This fixing bath is made fresh for each day's work. The pictures, when washed and dried, may be mounted on cardboard by means of starch, gum, or gelatine; paste is supposed to injure the picture under some circumstances. Exposure of the finished picture to *impure atmospheric vapours*, and to damp, is to be avoided. Mr. Malone has advised that the picture should be heated in a solution of caustic potash in order to secure its greater permanency. He also insists on the injurious action of sulphur in certain forms upon the print.

The process just described yields perfect results, and has superseded all others for the purpose of making 'Photogenic Drawings,' as they were formerly termed. Leaves, grasses, prints, feathers, lace, and indeed any well-defined object, translucent or not, may be depicted by simple contact with the prepared paper and subsequent exposure of the whole to light, under a sheet of glass pressed tightly on by springs or screws, as in the ordinary 'copying-frame.' In the absence of the sun, a quarter of an hour's exposure to the electric light will produce a good positive impression.

There is another branch of photography which is worthy of the attention of the student, but which has not yet come into practical operation in a perfectly satisfactory manner. It is that of photographic engraving. The labours of Niépce, Grove, Fizeau, Talbot, Pretsch, Poitevin, and others have done much to forward this art, and are well worthy of attention. Although the first Niépce laid the foundation of the art of Photographic Engraving, by his experiments on asphaltum, or Jew's pitch, it is to Mr. Talbot that we are indebted for opening up new processes in which organic substances such as starch, gum, albumen, and gelatine mixed with a salt of chromic acid furnish a photographic deposit which is capable of being worked by the ordinary processes of the engraver and lithographer. Mr. Talbot's plan is to pour upon a steel plate a mixture of bi-chromate of potash and gelatine, so as to obtain by drying a sensitive film: upon this film a positive photographic drawing is placed; now, by exposure to light, the gelatine becomes hardened, or nearly insoluble wherever the light has fallen through the positive picture. An engraving acid poured upon the plate will now etch only the shaded parts of the plate, and thus an engraved surface is obtained to be printed from with printer's ink. Mr. Pretsch, instead of etching the plate obtained by the action of the light on the gelatine compound, acts upon it by liquids; and what is most remarkable, gets a grained image in relief from which a mould is taken for the purpose of being electrotyped to form the copper-plate to print from. By proper manipulation, Mr. Pretsch can produce plates fit to print by the method called surface-printing, as with an ordinary wood block.

Of course, impressions taken from these plates by proper means can be conveyed to porcelain or glass, and burnt in by the enameller in the usual manner, or as at first devised by Mr. Malone, and described in a joint patent taken out with Mr. Talbot. To Messrs. Ponton and Becquerel we owe the first application of chromium to general photographic purposes. Mr. Pauncey and others have also devised ingenious processes by which pigments or inks may be made to adhere only to the altered gelatine and chromium compound surface, whether on paper, stone, glass, porcelain, or metals. These processes are as yet under trial. They lack the delicacy of tint of the albumen process, but they will doubtless yield ultimately valuable results.

Stimulated by the experiments of Sir John Herschel, M. Ed. Becquerel and others, M. Niépce de St. Victor commenced a series of beautiful experiments upon coloured flames and their photographic images. He laid before the Academy of Sciences, Paris, a detailed memoir upon the subject on the 4th of March, 1851. This was followed by others on June 2, 1851, Feb. 9, 1852, and November 8, 1852. By the method described in these papers, M. Niépce succeeded, he says, in obtaining upon silver plates which had been rendered sensitive by a chloride of copper, images which faithfully reproduced the colours in coloured engravings, flowers both artificial and natural, lay-figures dressed in stuffs and gold and silver lace, precious stones, &c. These were obtained both by the process of photographic printing and in the camera; the light and brilliant colours being obtained with comparative ease, but the darker and more sombre colours more slowly. The colours he rendered more vivid and at the same time more lasting by the action of ammonia. But beautiful as were the results, and much more nearly than in any other previous experiments as they seemed to approach the solution of the problem of photographing the colours of nature, they proved to be only comparatively permanent. The colours soon began to fade and eventually disappeared altogether. This method (due to M. Ed. Becquerel) M. Niépce named Heliochrome. M. Ed. Becquerel, by the use of silver plates, coated with a dark compound of chlorine and silver, obtained by the voltaic decomposition of hydrochloric acid, has succeeded in obtaining coloured images of the solar spectrum, but no method of fixing them permanently has been discovered.

---

* See also Mr. Hardwich's formula in the 'Journal of the Photographic Society' for 1860.

In scientific photography much remains to be done. We know but little of the properties of light in its influence on vegetation and animal life. Mr. Robert Hunt and others have, however, established some interesting facts in the former direction, and lately some experiments made upon the eggs of insects seem to show that light of various colours and intensities acts differently according to its colour and other peculiar qualities. There is no branch of science which will better repay the philosophical experimentalist for his investigations than that of photography. The most marvellous and unexpected results have been constantly obtained.

Those who would pursue photography further should consult Hunt's 'Researches on Light,' the Abbé Moigno's 'Répertoire d'Optique Moderne,' and Mr. Hardwich's 'Treatise on Photographic Chemistry.' There are many papers also of interest to be found in the 'Comptes Rendus' of the Paris Academy of Sciences, in our own Royal Society's 'Transactions,' and above all in the journals of the various Photographic Societies.

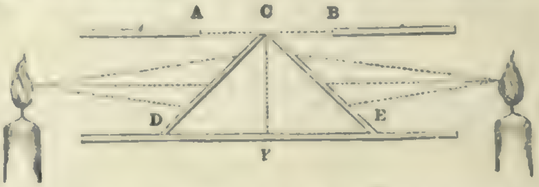
PHOTOMAGNETISM. A term sometimes applied to Dr. Faraday's beautiful discovery, by which the phenomena of magnetism have been placed in relation with those of light. [MAGNETISM.]

PHOTOMETER (literally "light-measurer," from φῶς and μέτρον), the name given to instruments constructed for the purpose of measuring the relative illuminating powers of different sources of light. When light or heat falls upon any substance, it is disposed of either by reflection, absorption, or transmission, or else by two of them, or all three of them combined. If two substances could be found which would reflect, absorb, and transmit calorific rays with the same intensity, and likewise reflect luminous rays equally, but differ in their powers of absorbing and transmitting light, we should then possess the means of at least ascertaining whether the absorption of light alone will produce effects analogous to what is observed to follow the absorption of heat. For this purpose it would be only necessary to prepare a differential thermometer whose bulbs were of the substances possessing the properties alluded to. The calorific rays accompanying the incident light would, by acting equally upon the two bulbs, produce no change in the indications of the instrument, and the only alteration, if any, which could ensue, would arise from the unequal absorption of light by the two bulbs. This alteration, however, when observed, though it might be considered a correct measure of the quantity absorbed, could not be taken for a measure of the quantity or brightness of the incident light, unless it could be further shown that the quantity absorbed by the same substance is proportional to the quantity of incident light, whatever may be its nature, that is, whether it be solar light, gas light, &c.

The photometer invented by Leslie differs from the instrument we have supposed, merely in its being in some respects less deserving of the name. It consists of a differential thermometer having one of its bulbs of plain transparent glass, the other of the same material coated either with Indian-ink or black enamel. Leslie remarks:—"The rays which fall on the clear ball pass through it without suffering obstruction; but those which strike the dark ball are stopped and absorbed at its surface, where, assuming a latent form, they act as heat. This heat will continue to accumulate till its further increase comes to be counterbalanced by an opposite dispersion, caused by the rise of temperature which the ball has come to acquire. At the point of equilibrium therefore the constant accessions of heat derived from the action of the incident light are exactly equalled by the corresponding portions of it again abstracted in the subsequent process of cooling. But in still air the rate of cooling is, within moderate limits, proportional to the excess of the temperature of the heated surface above that of the surrounding medium. Hence the space through which the coloured liquid sinks in the stem will measure the momentary impressions of light, or its actual intensity." Allowing that the light incident upon the clear ball is wholly transmitted, and that that which strikes the dark ball is wholly absorbed, assumes a latent form, and then acts as heat, it by no means follows that the effect produced upon the instrument was wholly or even chiefly attributable to the absorption of light, since we learn from Leslie's own experiments that the calorific rays which accompany the incident light would be more abundantly absorbed by the dark than by the light ball. This has since been so satisfactorily established by the observations of Thomson and others, that, as a measurer of light, the instrument may be regarded as useless.

The defects of Leslie's photometer were to a considerable extent obviated by the late Professor Ritchie, who, in 1825, communicated to the Royal Society the description of a new photometer. In order to intercept the calorific rays accompanying the light experimented upon, he transmitted the latter through a thick circular disc of glass into a metallic air-tight cylinder, the diameter of which was considerable compared with its depth. The axis of the cylinder was placed horizontally, and the aperture covered by the glass was the only one through which the light was admitted. Across the interior of the cylinder was stretched a circular sheet of dark paper, which absorbed the transmitted light, and, as was supposed, thereby converted it into heat, which became sensible by its expanding the air within the cylinder. A second cylinder of the same form and construction was placed by the side of the first so that the line of axes might coincide, but with the aperture for the admission of light turned in the contrary direction, and in that position they were connected by a bent thermometer tube containing a coloured fluid, which served to prevent the air of one cylinder from mixing with that of the other. So long as the air in the two cylinders possessed the same degree of elasticity, the level of the fluid in the two branches of the tube was of course the same; and a variation of level indicated a variation in the elasticity of the two bulks of air, arising from the more energetic action of the medium admitted through one aperture than through the other. To compare the relative intensities of two lights, the instrument was placed anywhere between them, and approached towards one or the other, until it was found that the position of the fluid in the tube was the same as when the instrument was not under the influence of the lights. Supposing the whole of the calorific rays and none of the luminous rays to have been intercepted by the glass, this position determined the point at which the intensity of the two lights was the same; and hence, since the intensity of light varies inversely as the square of the distance from its source [LIGHT], it followed that at equal distances from their respective sources their intensities were directly proportional to the squares of their observed distances from the instrument.

The same gentleman afterwards constructed a very simple instrument which affords a good measure of the relative brightness of two lights, provided they are of the same colour. The principle originated with Bouguer, who published it in his 'Traité d'Optique,' in 1760. The annexed figure represents a vertical section of the instrument. It consists of a rectangular box open at both ends and blackened upon its inner surface. On the top is a long narrow rectangular slip A B, covered with tissue or oiled paper. Within are two sheets of plane looking-glass, C D and C E, cut from the same slip to ensure uniformity of reflection. Each sheet has the same width as the box, and its length equal to the hypothenuse of a right angled isosceles triangle, whose side is the height of the box. Their reflecting surfaces are turned towards the open ends of the box, and their upper extremities rest against each other along a line, which in the figure is projected into the point C, and which divides the aperture A B into two equal parts, separated by a narrow strip of black card to prevent the mingling of the lights reflected from the two planes. In using the instrument it is placed between the lights whose intensities are to be compared, so that they may be reflected from C D and C E upon the tissue paper A B. It is then approached nearer to one or the other until, to an eye situated above A B, the two portions A C and B C appear equally illuminated, which, on account of the immediate proximity of A C and B C, may be determined with tolerable correctness, the colour of the two lights being supposed the same. The distances of the lights from the vertical C F being measured and squared, give the direct ratio of the intensities.



There is a mode of comparing the illuminating powers of two lights suggested by Count Rumford, which is remarkable for the facility with which it may be applied, and the simplicity of the requisite apparatus, nothing more being needed than a smooth surface of small extent and of a light uniform colour, and a blackened stick for throwing a shadow. The surface is illuminated by the two lights experimented upon, which are to be so placed, that when the stick is interposed between them and the surface, the two shadows may be nearly in contact, which will enable the eye to decide whether they are of equal depth, and will at the same time ensure the intercepting of rays equally inclined to the surface. So long as the shadows are of unequal depth, one of the lights must be brought nearer to or withdrawn farther from the surface till an equality of depth is obtained, and then the squares of the perpendicular distances of the lights from the surface give the ratio of their intensities. If an equality between the inclination of the intercepted rays to the surface cannot be obtained, then, when the two shadows are of the same depth, the intensities of the lights will be directly proportional to the squares of their perpendicular distances from the surface, and inversely proportional to the sines of the inclinations of the intercepted rays to the surface.

Suppose, for example, it were required to ascertain the illuminating power of a gas-light burning 5 cubic feet of gas per hour, as compared with that of a sperm candle burning 132 grains of spermaceti per hour; suppose the screen to be at 100 inches from the gas-light, and the candle only 27·75 inches in order to equalise the shadows. The relative intensities of the two lights are then found by squaring the distances of each light from the screen; the gas-light will diffuse a light which bears the same proportion to that of a candle as $100^2 : 27{\cdot}75^2$; or as 16 to 1.

Wheatstone's photometer consists of a small bright bead, to which a rapid looped motion is imparted, and this being placed between the two lights, both are seen reflected from the different points of the bead's surface. By the principle of persistence of impressions on the retina the two looped curves are seen of different degrees of brightness; the brighter light is to be removed until these curves appear of the same brightness, and the intensities of the lights are then as the squares of the distances as before. Bunsen's photometer consists of a compound disc of paper, of which the inner white disc is opaque, and the outer surrounding ring is made translucent by painting it with oil. When this is placed between the two lights, and viewed on one side, the opaque disc will be seen by reflection, and the translucent ring by transmission from the other light. The disc is then to be moved until both it and the ring appear to be equally illuminated, when the distances may be taken and squared as before. M. Babinet has contrived a polarising photometer. There are also photometers for measuring the relative brilliancy of the stars. These depend upon this principle:—that the brilliancy of the image of a star as seen through a telescope depends, *cæteris paribus*, on the size of the object-glass; by obscuring the outer rings of the object-glass the image of a star of high magnitude can be reduced to the light of a star of lower magnitude, as seen through the entire object-glass. The relative brilliancy of the two bodies may then be inferred from the diameters of the free object-glasses employed. In practice it is better to make use of two corresponding telescopes simultaneously. [STARS.]

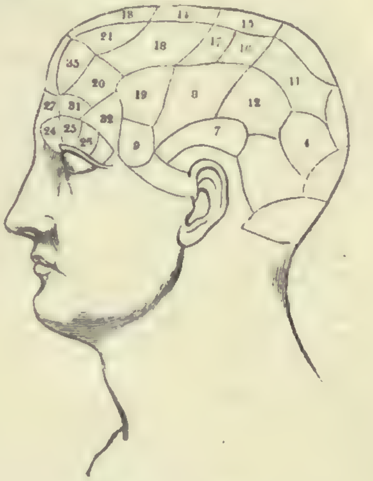
PHRASE, in music, a succession of sounds either in melody or harmony, expressing an unbroken sense more or less complete, and terminating in a pause (*repos*),—that is, a comparatively long note or a rest,—thus forming a cadence more or less perfect. Some authors have used the word *period* instead of phrase.

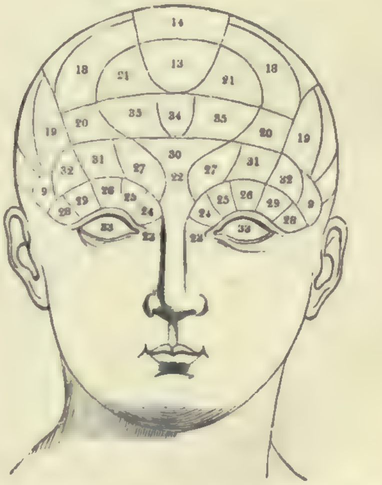
PHRENOLOGY (from φρήν, mind, and λόγος, discourse) is, in the words of Dr. Spurzheim, the doctrine of the special faculties of the mind, and of the relations between their manifestations and the body, particularly the brain. Without entering upon the question of the nature of the mind, or of the number or nature of its original faculties, it may be admitted as the result of all observation, and a fact on which nearly all physiologists are agreed, that the brain is the part of the body by means of which all the powers or faculties of the mind are manifested. The fundamental principles of phrenology, and those in which it chiefly differs from other psychological systems are, that the manifestation of each of the several faculties of the mind depends on a particular part of the brain, and that, *cæteris paribus*, the degree or strength in which each faculty is manifested in each individual, depends on the size of its appropriated portion of the brain, or (as it is termed) its organ.

The first principle, that of the plurality of organs in the brain, is supposed to be supported, 1, by the analogy of the other compound organs or systems in the body, in which each part has its special function; as, for example, in the digestive system, in which the stomach, liver, and other organs perform each their separate share in the common result of digestion of the food; 2, by the different degrees in which, in different individuals, the several mental functions are manifested. Even in the earliest period of childhood, and before education can be imagined to have exercised any influence on the mind, children exhibit the most varied dispositions—each presents some predominant propensity, or evinces a singular aptness in some study or pursuit; and it is a matter of daily observation that every one has his peculiar talent or propensity. But it is difficult to imagine how this could be the case, if the manifestation of each faculty depended on the whole of the brain; different conditions of the whole mass might affect the mind generally, depressing or exalting all its functions in an equal degree, but could not permit one faculty to be strongly and another weakly manifested. 3. The plurality of organs in the brain is supported by the phenomena of some forms of mental derangement. It is not usual for all the mental faculties in an insane person to be equally disordered; it often happens that the strength of some is increased, while that of others is diminished; and in many cases one function only of the mind is deranged, while all the rest are performed in a natural manner. 4. The same opinion is supported by the fact that the several mental faculties are developed to their greatest strength at different periods of life, some being exercised with great energy in childhood, others only in adult age; and that as their energy decreases in old age, there is not a gradual and equal diminution of power in all of them at once, but, on the contrary, a diminution in one or more, while others retain their full strength, or even increase in power. 5. The plurality of cerebral organs appears to be indicated by the phenomena of dreams, in which only a part of the mental faculties are at rest or asleep, while the others are awake, and, it is presumed, are exercised through the medium of the parts of the brain appropriated to them. 6. It is stated that the examination of the brains of individuals, each remarkable for some peculiar propensity or talent, has demonstrated a constant correspondence in the development of a certain portion of the brain; and that thus the results of the observations upon which phrenology was first founded by Dr. Gall, exactly coincide with and confirm the arguments by which its truths may, *à priori*, be made to seem probable. Lastly, pain has been felt in an organ when the faculty with which it is presumed to be connected has been greatly excited; and when a faculty has been morbidly manifested during life, disease has sometimes been found to have affected the corresponding part of the brain.

The preceding arguments for the existence, in the general mass of the brain, of several organs or instruments for the manifestation of the different powers of the mind, form also the basis of the rules by which those powers which may be called primitive, or original, are determined. Every power of the mind is regarded by phrenologists as a primitive faculty, and is considered to be manifested through the medium of a separate organ, which, 1, exists in one kind of animal and not in another; 2, which varies in the sexes of the same species; 3, which is not proportionate to the other faculties of the same individual; 4, which does not manifest itself simultaneously with the other faculties, that is, which appears or disappears earlier or later than they; 5, which may act or repose singly; 6, which individually is propagated in a distinct manner from parents to children; and 7, which singly may preserve its proper state of health or be affected by disease.

In accordance with these rules Gall enumerated nearly thirty primitive mental faculties, which are admitted, with more or less of modification, by all the phrenologists of the present day; and their number has been augmented by Spurzheim to thirty-five. These faculties Spurzheim divided into moral, or affective, and intellectual. The affective faculties or feelings he again divided into *propensities*, including all those which produce only desires or inclinations, and *sentiments*, including such as not only produce a desire to act, but are combined with some other emotion or affection which is not mere propensity. The intellectual faculties also he divided into the *perceptive* and the *reflective*. The subjoined figures and the references to them will at once indicate this division of the mental faculties, and the situations on the exterior of the head which are supposed to correspond with the portions of the brain belonging to each, according to the system of Dr. Spurzheim. We have also added the figures by which the several organs were marked by Mr. Combe, in the first and second editions of his 'System of Phrenology;' in the later editions he has followed the enumeration of Dr. Spurzheim.



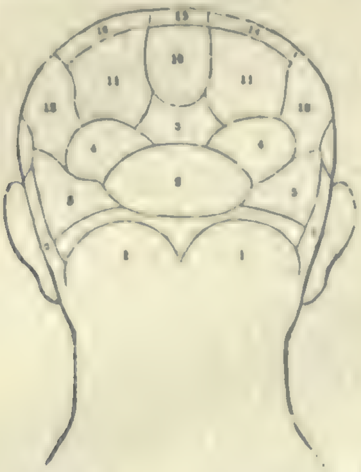


1. *Amativeness* is the mental faculty which produces the propensity to physical love, or, as it was termed by Dr. Gall, the instinct of propagation.* Its organ is the cerebellum, and its energy is indicated by

---

* It may be necessary to mention that the chief modifications introduced into the system of Gall by Spurzheim (whose arrangement is here adopted as being received by the great majority of phrenologists in this country) are expressed in the differences of their terms. Gall designated the organs according to the actions to which he believed their predominance led; Spurzheim according to the nature of the faculties. [See further, GALL; SPURZHEIM, in BIOG. DIV.]

the extent of the space on each side of the head between the mastoid process, immediately behind the ear and the spine of the occipital bone.



Combe.	Spurzheim.	Affective. I. *Propensities.*
1.	1.	Amativeness.
2.	2.	Philoprogenitiveness.
3.	3.	Inhabitiveness.
4.	4.	Adhesiveness.
5.	5.	Combativeness.
6.	6.	Destructiveness.
9.	7.	Secretiveness.
8.	8.	Acquisitiveness.
7.	9.	Constructiveness.
		II. *Sentiments.*
10.	10.	Self-Esteem.
11.	11.	Love of Approbation.
12.	12.	Cautiousness.
13.	13.	Benevolence.
14.	14.	Veneration.
18.	15.	Firmness.
17.	16.	Conscientiousness.
15.	17.	Hope.
	18.	Marvellousness.
16.	19.	Ideality.
32.	20.	Mirthfulness or Gayness (Wit).
33.	21.	Imitation.

Combe.	Spurzheim.	Intellectual. I. *Perceptive.*
19.	22.	Individuality.
20.	23.	Configuration.
21.	24.	Size.
22.	25.	Weight and Resistance.
23.	26.	Colour.
24.	27.	Locality.

28.	32.	Melody.
29.	33.	Language.
		II. *Reflective.*
30.	34.	Comparison.
31.	35.	Causality.

2. *Philoprogenitiveness* is the faculty which produces the feeling of love towards offspring. The evidence by which this is admitted as a fundamental faculty of the mind may afford an example of the application of the seven rules already given for determining them. There are many animals which take no care of their progeny, as reptiles and fish, and, among birds, the cuckoo. In many species of animals the females alone take care of their offspring, as among cats, cattle, sheep, &c., and in general, even when both parents protect their young, the attachment of the mother is the stronger. The love of offspring bears no proportion to the other mental faculties, but is shared alike by men and brutes, and among the former is often felt as intensely by the most degraded as by the most exalted of the species. The love of offspring is sometimes, on the contrary, almost completely suppressed. Cases of insanity have not unfrequently occurred in which parental love was lost or greatly diminished; while others are recorded in which the love of offspring has been almost the only feeling which remained unimpaired. The seat of this organ is directly above the middle of that of amativeness; and the energy of the faculty is indicated by the general protuberance of the occipital bone. Though placed in the middle of the head, this organ is of course, like all the others, double, and extends to an equal distance on each side of the median line.

3. *Inhabitiveness.*—The existence of this, the propensity to inhabit particular regions or countries, which produces the love of home, and which determines in each species the dwelling and mode of life which is best adapted to it, is regarded as doubtful. Dr. Gall placed in this situation the organ of pride in man, and that of the instinct in animals which prompts them to seek and inhabit the heights of mountains or to fly high in the air, believing that faculties which are merely physical in brutes may become moral in man, and that there is an analogy between the feelings which prompt to the pursuit of moral and those which excite the desire of physical elevation. Mr. Combe and many of the Edinburgh school of phrenology name this the organ of concentrativeness, believing that it corresponds to the faculty of maintaining two or more powers in simultaneous and combined activity, so that they may be directed towards one object, a faculty disposing to sedentary pursuits, and a close and steady attention, especially by meditation, to a given object. At present it is agreed that the evidence is insufficient for the complete establishment of either of these opinions.

4. *Adhesiveness* is the propensity to attachment or friendship, by which individuals of the same or different kinds are induced to associate together, and which causes men to be attached to the various objects amongst which they are placed. Its objects are disinterested friendship, marriage, society, and attachment in general. The organ of this faculty is believed to be situated at No. 4, immediately above and to the outer side of that of philoprogenitiveness.

5. *Combativeness* is the natural disposition which men and animals feel in various degrees to quarrel or fight. In order to discover its organ, Dr. Gall is said to have been in the habit of calling together boys from the streets to endeavour to make them fight. There were of course some who were fond of it, and others who were peaceable and timid: in the former the part of the head marked 5 was prominent; in the latter it was flattened or depressed. The same difference is said to exist in the formation of this part, in correspondence with the strength of this disposition in the several species of animals, and remarkably in the different varieties of dogs.

6. *Destructiveness*, or the propensity to destroy, is the feeling which is gratified by any kind or mode of destruction. Spurzheim ascribed to it the tendency to all kinds of destruction, whatever were their objects, or the mode in which they were effected. Thus defined, the propensity to murder is but one of the directions which the disposition for destruction may take, and one from which in a conscientious and benevolent man it would always be diverted. In such a man this propensity will be exercised for an innocent or even a useful end, as the procuring of food by the slaughter of animals, &c.; in another, in whom its influence is less counterbalanced, there will exist an indifference to the suffering and calamities of others, or even a positive pleasure in beholding or contemplating them; in a third, in whom it is unrestrained, it may break out in acts of violence and love of blood-shedding in every form. In the diseased condition of its organ this propensity is regarded as the source of the irresistible desire for the destruction of life, of which so many lamentable examples are known, and which is commonly called homicidal monomania. The seat of the organ of destructiveness is on each side of the head immediately above the ear, at No. 6; and its various degrees of development may be seen in a comparison of the width at this part of the heads of carnivorous and herbivorous animals.

7. *Secretiveness* is the propensity to act in a clandestine manner; to conceal emotion, and to be secret in thoughts, words, things, and projects. Its most frequent bad results are cunning and hypocrisy; and the most usual direction which it takes for good ends is prudence. The organ of this propensity is immediately above that of destructiveness, at No. 7. (In the casts made in accordance with the enumeration of the faculties employed by Mr. Combe, in the early editions of his 'System of Phrenology,' this organ is marked 9.)

8. *Acquisitiveness* is the propensity to acquire. Its organ being found very large in notorious thieves, Dr. Gall conceived that there was a natural disposition to theft. Dr. Spurzheim, on the other hand, makes no limitation as to the purpose or mode of acquisition, which he believes to be determined in each case by the degrees in which the several other faculties are developed. Variously modified, the propensity leads in some to the prudent accumulation of property by honest means; in others, to avaricious and purposeless money making by any method; in others, to theft or fraud. The seat of its organ is at the back part of the temples.

9. *Constructiveness* is the faculty which leads to construction of all kinds: guided by it birds build their nests, rabbits burrow, beavers make their huts; and men are directed by it to manufactures, the practice of the several branches of the fine arts, building, and various manual operations. Its organ is situated at the lower part of the temple, at 9.

10. *Self-esteem* is the sentiment which gives an individual a high opinion of himself, which in excess produces pride and arrogance, and when moderate and modified by other superior faculties imparts dignity to the mind, and renders it hostile to everything that is mean or degrading. In a state of derangement the morbid excitement of this faculty leads the insane to imagine themselves exalted to thrones or to divinity. The seat of its organ is at the middle of the upper and back part of the head (10), directly above inhabitiveness (3), with which Dr. Gall (as already mentioned) confounded it.

11. *Love of Approbation*, according to Dr. Spurzheim, is the sentiment which makes us regard the opinion entertained of us, and induces the question—What will the world or the people say? It is fond of approbation in general, without attending to the manner of acquiring it; and may therefore be directed to objects of the highest importance, as well as to such as are of no moment, or are even hurtful. Ambition is the distinguishing epithet of its agency, if the subject aspired to be of great importance; vanity, if claim be laid to distinction on the score of trifles. The organ is seated on each side of self-esteem; when much developed it generally elongates the upper and back part of the head, but is sometimes spread out laterally so as to widen rather than lengthen it.

12. *Cautiousness* is the disposition of the mind which leads a man or an animal to take precautions in whatever he has to do; "it doubts, says *but*, and continually exclaims, *take care*" (Spurzheim). When too

active it causes irresolution, anxiety, and melancholy. Its organ is situated on the upper lateral and posterior part of the head, between destructiveness and self-esteem.

13. *Benevolence* is the disposition of the mind from which result compassion, kindness, philanthropy, mildness, charity, and various other amiable social virtues. Its existence as a fundamental power of the mind is considered to be proved by the rules above mentioned, and by which, it may be again observed, the existence of all the preceding and following faculties is determined; the seat of its organ is the upper and middle part of the forehead, just where the hair begins to grow.

14. *Veneration.* The organ of this faculty was called by Dr. Gall the organ of religion, and he believed that the disposition to the worship of God was directly proportionate to its development. Dr. Spurzheim has here again extended the scope of the faculty, by making it the cause of veneration or respect in general, whether directed to divine or human beings, or to inanimate objects. When the organ of this sentiment is much developed, the head is remarkably elevated; and it was by observing (as Lavater had before done) this peculiarity in the shape of the heads of very pious persons, that the position of the organ on the front part of the top of the middle of the head was determined.

15. *Firmness* is the faculty which gives constancy and perseverance to the other powers, and contributes to maintain their activity. In its various combinations with other faculties, the results to which it leads differ considerably: with much self-esteem and love of approbation, it produces an obstinate persistence in the pursuit of honour and rank; with benevolence, it excites the most active and persevering philanthropy; with destructiveness and acquisitiveness, it may excite to daring acts of murder and rapine. When, on the other hand, this faculty is little developed, it leaves men inconstant, and makes them the mere creatures of circumstances. Its organ is situated at the very top of the head, at 15.

16. *Conscientiousness* is the fundamental and innate sentiment which disposes mankind to look and to wish for justice. The existence of this feeling in a high degree is one of the chief constituents of a noble mind, and the strongest foundation of morality; its deficiency leaves men with little restraint to prevent them from following the impulses of all their worse propensities, and from striving to attain their ends by the most unworthy means. The situation of the organ of conscientiousness is on the upper part of the head, on each side of that of firmness.

17. *Hope* is the sentiment which induces men to believe in the possibility of whatever their other faculties desire; it is not mere desire, for that may continue without any expectation of being ever gratified. The different degrees in which it is developed will lead one person to be continually building, as it is said, castles in the air, and another to despair of success even in favourable circumstances. It is this sentiment, also, which inspires the hope of a future state and of immortality. Its organ is situated on each side of that of veneration.

18. *Marvellousness, or wonder,* is the sentiment which is principally manifested by a belief in miraculous and supernatural circumstances, and which leads men to be amused with everything that can excite their surprise and wonder. Its organ is situated immediately in front of that of hope.

19. *Ideality.* Dr. Gall regarded the organ of this faculty as the organ of poetry, finding it much developed in all the great poets of ancient and modern times. But it is also large in some who, though they may be fond of poetical conceptions, are not poets themselves. Dr. Spurzheim therefore believes that the essential nature of this sentiment is to impress a peculiar character called poetical or ideal, and to vivify the other faculties; to give a sense and love of beauty; to produce sublimity of conception, and excite warmth of imagination and expression. The organ of this sentiment is placed by the side of marvellousness, and the two frequently act together.

20. *Mirthfulness,* or *Wit.* Spurzheim regards this faculty as affective, not as intellectual, in which view it is considered by Gall, and by the principal phrenologists of the Edinburgh school. He describes it as a sentiment which disposes men to view everything in a gay or joyful manner, and which, according to its various applications in different circumstances, and its modifications by being variously combined with other faculties, produces wit, good humour, caricature, mockery, irony, sarcasms, epigrams, and satires. Its organ is situated in the upper and lateral part of the forehead, and in the earlier Edinburgh casts is marked 32.

21. *Imitation.* Those who have this faculty highly developed are fond of acting, and of imitating the gestures, voices, manners, and in general all the manifestations of man and animals. It is generally more active in children than in adults: the former always learn a great deal by imitation; of the latter, some only employ it much, and these are usually marked by the gestures with which they speak, imitating the habits and manners of whatever forms the subject of their conversation. Its organ is situated at the front of the head, and on each side of benevolence.

22. *Individuality* is, in Spurzheim's arrangement, the first of those intellectual faculties which perceive the existence of external objects and their physical qualities. It is the faculty which recognises the existence of individual beings. It is this, also, which in excess induces men to personify everything of which they speak, whether mere qualities or abstract ideas, or even phenomena, such as motion, life, the passions, &c. Its organ is situated behind the root of the nose, and its greater development enlarges the forehead between the eyebrows.

23. *Configuration,* or *Form,* is the power which takes cognisance of forms and figures generally. One of its peculiar applications, and that by which its organ was first discovered by Dr. Gall, is observed in the power which some individuals possess of remembering the forms and features of different persons; another is shown in the love of portraits, or in the ability to take the likenesses of persons and things. Its organ is situated in the internal angle of the orbit, and when large it pushes the eyeball outwards and downwards, giving the person in whom it is thus developed a somewhat squinting appearance, and making his eyes appear unusually wide apart.

24. *Size.* This is the faculty which measures the size of bodies, as distinguished from their form, which is appreciated by the preceding power. Its organ is placed at the inner corner of the arch of the eyebrow.

25. *Weight.* It is believed that the mind estimates the weight and resistance, as well as many of the other qualities of bodies, not by the sense of feeling, but by a peculiar internal operation, which must require a special organ. Dr. Spurzheim conjectures that its situation is behind the orbit, in the neighbourhood of configuration and size.

26. *Colouring.* There appears to be a peculiar faculty for the full appreciation of the relations of colour. For though few are incapable of perceiving the differences of colour in the objects around them, yet all have not the same power in this respect, nor have all the same facility in recollecting or judging of their relations. Many artists who draw well cannot colour; others are good colourists, but cannot imitate or design forms. The organ of this power, which must from these and other similar circumstances be regarded as an original faculty of the mind, is placed in the middle of the arch of the eyebrow.

27. *Locality.* This is the faculty by which we appreciate and remember the places occupied by objects around us; the mental power which makes the traveller, geographer, and landscape-painter; which recollects localities, and gives notions of perspective. It is remarkably shown in the power which many animals exhibit in tracing their way through great distances in migration, or in returning to their homes; and it gives men the propensity to travel, which many have so remarkably exhibited. Its organ is placed above and on each side of the root of the nose.

28. *Calculation,* or *Number,* might be called the faculty of arithmetic; whatever concerns calculation or number belongs to it, and hence Mr. Combe and many others speak of its organ as that of number. In those in whom the power of calculation is much developed, the external angle of the eyebrow is either much pressed downwards or elevated; the organ of this faculty being situated beneath that part of the brow.

29. *Order.* It is believed that there is a faculty which gives a disposition to arrange and put things in order; as, for example, in a library to place books according to their size and form; in a collection of natural history to make each subject occupy its right situation according to its configuration, or colour, or size. Cleanliness also seems to depend on it; and it produces the pleasure of seeing things complete. Its organ is situated between those of colouring and calculation.

30. *Eventuality.* Individuals who have this organ large are attentive to all that happens around them, to phenomena, to events, to facts; they are fond of history and of anecdotes; are inquisitive, and desire information on every branch of natural knowledge. Individuality takes cognisance of things which are, the names of which are nouns; and eventuality, of things which happen, the names of which are verbs. The organ is situated in the middle of the forehead, and those in whom it is much developed have a peculiar prominence of this part of the skull.

31. *Time.*—The faculty of time conceives the duration of phenomena, their simultaneousness or succession. Its organ is situated above the middle of the eyebrow.

32. *Melody or Tune.*—The organ of tune bears the same relation to the ears as that of colour does to the eyes. The ear is the instrument by which sounds are heard, but it has no recollection of them, and does not judge of their relations; these are the offices of a peculiar and original mental power, whose organ is above the outer part of the eyebrow, so that when much developed, it enlarges the lower and lateral part of the forehead.

33. *Language.*—This is the faculty which makes us acquainted with arbitrary signs, which remembers them, judges of their relations, and gives a disposition to indulge in all exercises connected with words. Its organ was the first that Dr. Gall discovered: in his youth he observed that while he had great difficulty in committing his lessons to memory, there were many boys who could easily learn by heart even things which they did not understand so well as he did. He noticed that all these boys were "bull-eyed," that is, had a peculiar prominence of the eye-ball, which seemed to project from its socket. Subsequent observation enabled him to confirm the opinion that the organ of verbal knowledge is situated at the very back part of the orbit, which is, with the eye, pushed forward by it when it is much developed.

34. *Comparison* is the reflective faculty which compares the sensations and ideas excited by all the other faculties, and points out their difference, analogy, similitude, or identity. It induces men to argue from analogy, to draw illustrations of their subjects from things well known, to speak by parables, and explain by examples and similes. It leads to the invention and employment of figurative language, and according to the degree of its national development, the language of each country will be full of or deficient in figures and metaphors. Its organ is situated in the middle of the upper part of the forehead.

35. *Causality.*—The reflective faculty which engages men in the study of the causes and origins of things, and which guides to the employment of processes of induction, is thus named. The faculty of individuality makes us acquainted with objects; eventuality, with facts; comparison, with the analogy, identity, difference, and other relations of things; and causality leads us to search for their causes: together, these faculties, when fully developed, constitute the truly philosophic mind. The organ of causality is at the upper part of the forehead, on each side of comparison, and their coincident development gives the peculiar fullness of the front of the head, which is universally regarded as the sign of a powerful reasoning intellect.

Having now given a general view of the principles of phrenology, as stated in the writings of Dr. Spurzheim, and adopted by most of the present advocates of the system, it will probably be desirable to consider how far it is what it "professes to be, a system of philosophy of the human mind, founded on the physiology of the brain." (Combe, 'System of Phrenology,' p. 1.) Neglecting for the present all metaphysical views on the subject, and regarding the theory of the existence of some such primary faculties of the mind as are assumed in phrenology, and of the dependence of each upon a separate portion of the brain, as one deserving of being tested by observation, we will examine only how far the doctrine, as it now stands, is supported by facts of anatomy and physiology, and whether it is capable of being established by the evidence of craniological investigation.

Many of the objections commonly made against phrenology are undoubtedly of little weight: such for example are the statements that in consequence of the irregularities of thickness in the coverings of the brain, it is impossible to determine its form by examination of the exterior. This objection only shows that there are sources of fallacy in the practice of craniology, a fact which no phrenologist denies. But on the greater part of the head, the differences of thickness of the coverings of the brain are not such as would lead into error; the majority of them are nearly constant in their amount, and are easily recognised by any one acquainted with the anatomy of the skull, and the rest are not sufficient to give that degree of elevation or depression to any part of the exterior of the head which would be regarded as indicative of excessive or deficient development of any organ. No one accustomed to post mortem examination can hesitate to admit that the form of the greater part of the exterior of the head corresponds as nearly with that of the surface of the brain as is necessary for craniological purposes. The parts in which the correspondence is often inexact are those over and in the neighbourhood of the eyebrows. The thickness of the superciliary ridge of the frontal bone is variable, and would certainly in some cases make a moderately developed organ appear large; and still more the size of the frontal sinuses (the cavities between the two plates of the frontal bone immediately above and by the sides of the root of the nose) must always be a source of fallacy in determining the size of that part of the adult brain in which the organs of form, individuality, size, and weight, and part of that of locality are supposed to be placed. The estimate of the supposed organ of language also, which is indicated by the prominence of the eye, must be liable to error from the varying quantity of the contents of the orbit. From these several circumstances however the utmost objection that can be raised is, that there must in general be some difficulty in determining the size of these few parts of the brain. In consequence of disease also the whole or parts of the brain may diminish in size without being accompanied by any corresponding change in the external form of the skull.[*] But as a general rule the subjects of disease are excluded in phrenological observations. The objection that parts of the brain have been destroyed without affecting any of the faculties of the mind is also of little weight, unless it be first proved that the organs are not double. The cases of this kind recorded before the promulgation of phrenology cannot fairly be deduced as evidence, because the statements which they contain relative to the preservation of the mental faculties after injuries of the brain, regard only the general powers of sensation, volition, memory, imagination, &c., and not the primary faculties of phrenologists, some of which might have been deficient without their loss being observed. The observations that have been made since, it must be confessed, are not of more weight against phrenology, than those of the loss of peculiar faculties (especially those of language and amativeness) by injury and disease of the brain are in its favour. Experimental mutilations of the brains of animals must be regarded as affording still less conclusive evidence; when a part of the brain is thus removed, the condition of the whole of the rest of its mass is altered by the removal of the pressure of the skull, exposure to the influence of the atmosphere, interference with the circulation of its blood, &c. It is impossible that a correct conclusion upon any part of the functions of the brain should be drawn from experiments of this kind; and the whole of the arguments deduced from them by Rudolphi, Magendie, and others, may therefore be neglected.

Fully admitting the insufficiency of these, as of some other minor objections to phrenology, we come to the consideration of some which must be regarded as more important. If phrenology were true, it might be expected that its applications would extend through the whole animal kingdom, and that according to the degree in which each mental faculty is developed in each animal, we should find a corresponding portion of its brain large or small when compared with that of man. Yet this is so far from being the case, that phrenologists are compelled to rest their opinions almost exclusively on evidence derived from the comparison of the brains of different individuals of the same species, and to suppose that though many faculties are the same in man and the lower animals, yet in each species they are manifested in some peculiar form and structure not admitting of comparison with those of man. This is evidently contrary to the analogical mode of reasoning which we pursue in other instances; all eyes, all ears, and all organs of smell are formed on the same principles, and so we might presume are all organs of the mind; so that as by the size or extent of distribution of their nerves we can determine in each animal the power of its sense of smell or sight or hearing, so by the size of a special part of the brain we might in each estimate the energy of some corresponding faculty. Between the vertebrate and the invertebrate animals, for example, there is an abrupt step in the condition of the nervous system; the brain and spinal cord of the lowest of the former class differ widely from the supra-œsophageal ganglion and the gangliated cords of the latter; we might therefore expect to find an equally sudden deterioration of mental power. Yet none such occurs: but although the supra-œsophageal ganglion (which may be regarded as the brain of insects) is only so much larger than the rest of their ganglia as is proportionate to the number of organs requiring to be supplied with nerves from it, yet none will deny that many insects exhibit more exalted psychical powers than the majority of either fish or reptiles do. But, taking the vertebrata alone, in all of which there is a certain general plan observed in the nervous system, it is not found that in each order or species, when compared with the rest, the parts of the brain are developed in proportion to the energy of the faculty ascribed to each of them. The phrenological function of the cerebellum, for example, is almost equally powerful in all species; yet the absolute and proportionate size of the cerebellum regularly lessens as one descends through the order of vertebrata, and in the batrachia, in which its supposed function is extremely energetic, it is a mere narrow cord passing across the fourth ventricle. The part of the brain too, which is found decreasing as it is examined in the descending scale of vertebrate animals, is not the anterior, the seat of the intellectual faculties, but the posterior, in which are placed the organs of the animal propensities. A fair mode of comparison to determine this is to be found in the degree in which the hinder part of the cerebrum overlaps the cerebellum; in man alone does the former ever completely cover the latter; in idiots it often fails to do so; in monkeys it covers a still less portion; and continuing to descend through mammalia, the posterior lobes of the cerebrum grow constantly smaller, and the cerebellum is proportionally more, and at last completely, exposed. From these facts it might be assumed that the posterior lobes are the seat of some intellectual faculties; and such an assumption can be avoided only by believing that there is no analogy between the form of the posterior lobes of the cerebrum in man and mammalia. It is not denied that these apparent anomalies may exist, and yet phrenology may be true; but in balancing the probabilities of its truth or falsity, they must not be neglected.

The necessity which is felt of limiting the comparison of cerebral and psychical development to individuals of the same species[*] proves that some other condition than size is essential in determining the energy of each faculty, and that peculiarity of form and position of parts of the brain may give the external appearance of excess or deficiency of size; admissions which must throw doubt on the sufficiency of the only means which phrenology possesses of collecting facts to support its theory. If structure and form render it impossible by the size alone to determine the comparative psychical characters of two individuals of different species, the same conditions may often disturb the results that should proceed from comparisons of size in the organs of two of the same species.

---

[*] It is commonly stated in phrenological works that as the brain diminishes in size the internal table of the skull grows inwards, increasing the thickness of the skull. The writer is convinced from numerous observations that the space left in the cavity of the skull by the diminution of the volume of the brain is in a large majority of instances filled up by an accumulation of fluid in the pia mater and in the ventricles [Brain, in Nat. Hist. Div.]; and that the skull rarely undergoes any such change in its thickness as would be phrenologically important. Even when the whole, or, as is more rarely the case, a part of the skull does thus increase in thickness, it does not indicate that there was wasting of the parts of the brain immediately beneath it, but more frequently is consequent on a diminution of parts deeply situated, as the optic thalami and corpora striata. The examination of the skulls of those in whom particular organs are supposed to have wasted, must therefore be too fallacious to admit of any conclusions being drawn from them.

[*] Although, to meet the objections mentioned above, phrenologists insist on the necessity of comparing only individuals of the same species, it is to be observed that they readily make use of illustrations favourable to their opinions obtained by the contrary means, as, for example, in the determination of the organs of combativeness and destructiveness by a comparison of carnivorous and herbivorous animals, and of that of constructiveness by comparing the heads of the hare and the rabbit.

In the limited field of the comparison of different individuals of the same species, phrenology is said by its supporters to be established by numberless facts of the correspondence of strength or weakness of each of the faculties with proportionate extent or deficiency of development of its organ; and they maintain that conclusions thus drawn from facts can be overthrown only by facts that contradict them.* But the numerous sources of fallacy which render the presumed facts for phrenology doubtful, present as great an obstacle to the collection of facts against it; and although its theory, which possesses so much plausibility, cannot be altogether overthrown by anything but well-ascertained facts, yet it is fair for any one to withhold his assent to it till he believes that it is supported by a sufficient number of positive and unerring observations; and the more so when he finds it opposed by some, however few, facts, and incapable of explaining several circumstances that might be expected to be placed under its laws. For these reasons the fallacies to which craniological observation is subject must be admitted as casting doubt upon the testimony of phrenologists, who, granting that they are unwilling to deceive, may yet, like all other observers, be charged with the liability to be themselves deceived. We believe that in this we do not step at all beyond the commonly adopted rules of judging from evidence, according to which it is open to every one to disbelieve statements and conclusions that seem to him improbable, although he may not be in a position to disprove them all by facts.

Judging by these rules, the very perfection to which phrenology is supposed to have nearly attained is strong evidence of its improbability. No one will deny that, in its connection with the body, the human mind must be the most difficult branch of physiology. Yet if phrenology be true, the physiology of the brain is more advanced than that of any other organ in the body; and the improbability is presented that two physiologists accomplished more in about 50 years of study of the most difficult branch of the science of life than the united generations of physiologists of all classes for near 2000 years have effected in the most easy. There is not one function of the living body which can be so perfectly illustrated by the most accomplished physiologists as (if phrenology be true) the functions of the mind can be elucidated by a mediocre adherent to its doctrines; and this too while, to every source of fallacy which it has in common with other departments of physiology, it is subject to still greater which are peculiar to itself.

The improbability that the labour bestowed upon phrenology should have had so extraordinary a result, will appear greater when some of the fallacies are pointed out to which the observations that serve for its basis are subject. Admitting that the size of a part of the brain may be taken as a measure of the power of the faculty of which it is presumed to be the organ, it can be a correct measure of power only when all other conditions are the same. This is admitted by phrenologists, who maintain only that, *cœteris paribus*, size is a measure of power; and it may be admitted that in this proposition they are supported by the analogy of other organs of the body. But in all of them, and therefore probably in the brain, the other conditions are fully as important as size; yet phrenologists in their usual practice refer to quality of the brain only when they find that the indications of quantity are manifestly opposed to their opinions. Moreover the estimate which phrenologists make of the quality of the brain, by observing the external appearance and temperament of the individual, is as fallacious as a measure of the state of the whole mass, and is valueless as a sign of the structural condition of each of its several parts. But any one part of the brain may as well differ from the rest in quality as in quantity; an assumption which the phenomena of local diseases, which are much more common than general diseases of the brain, are sufficient to establish, and which phrenologists themselves admit in their explanation of monomania. There is here therefore a manifest source of fallacy in every phrenological observation; a source of fallacy comparable with, but greater than, most of those which have so long obscured the knowledge of the more simple departments of physiology. No one who has had any opportunity of appreciating the difficulty of analysing observations of which such a varying source of error as is here indicated forms a constant part, can avoid suspecting that phrenologists, when they pretend to have overcome the difficulty, have merely wandered into the facilities of error.

Again, if the condition of quality (in which are included many important circumstances connected with both the temporary and permanent state of the brain, each of which is probably not less important than size) must be regarded as a constant source of inappreciable error in estimating the material condition of the organs, there is scarcely less fallibility in the other element of a phrenological observation, namely, the determination of the mental character of the individual examined. The actions of men are taken as the index to their phrenological state; but (not to mention the cases in which men feign the possession of dispositions and opinions which are not their own) it is evident that in numerous instances, in which there is no intention to deceive, the same actions proceed from different motives, and this phrenologists fully admit, for in many cases in which the size of certain parts of the brain does not agree with the apparent energy of the functions usually allotted to them, they refer the prominent actions of the individual under examination to the excess or defect of some other parts of the brain. But if in one case an apparent disagreement between the state of any faculty and of its presumed organ is thus easily capable of explanation by the condition of other faculties and organs, then in every case the state of all the other faculties must become an inappreciable source of fallacy in endeavouring to estimate the condition of any one.

It is unfair to make use of these supplemental modes of determining characters in cases that are opposed to phrenology, and not to admit their influence in those which seem favourable to it. If the actions of a man are to be taken as the index of his mind—but if at the same time it is allowed that the same actions may result from different propensities, desires, and tastes, it is evident that it will be almost impossible to bring the evidence of facts to bear against phrenology, in which there must then be so many facilities of escape from conviction of error. If, to take an illustration from the writings of Sir G. Mackenzie, a young man in whom locality and inhabitiveness are very moderately developed is yet irresistibly impelled to go to sea, by a mechanical genius, and by attachment to the mechanism of a ship, conjoined with perseverance, courage, love of approbation, and ideality, there can surely be no certainty that any one propensity is proportioned to the condition of a single organ rather than to the combined condition of several others.

When we point out these sources of fallacy in every phrenological observation that has been made, and add to them the doubt which is cast upon it by the total absence of any anatomical peculiarity in the brain correspondent with the presumed separation of its organs, and by the failure of its application in the comparison of the psychical condition of man and animals, sufficient has been done to show that a person exercises a justifiable and even a philosophical degree of caution in withholding his assent from phrenology as it at present stands. He may grant, as the writer does, that its theory is ingenious and probable; that its plan of classifying the faculties of the mind is probably more natural than that of any other psychological system; that the existence of many of the assumed faculties admits of little doubt; that a comparison of the heads of different nations and individuals renders it almost certain that the general divisions of the part of the human cerebrum are correct; that in many cases, on balancing the evidence on each side, the result is on the whole favourable to the belief that the positions of several of the organs in each part of the brain have been nearly determined; but without further and very extended inquiry, and that made with a just appreciation of the difficulties of attaining to facts, when so many of the elements of the observations are inappreciable, and conducted by a disposition to doubt rather than to find confirmation of the doctrine assumed, he will hesitate to accept its theory further than as a direction to his inquiries, and will refuse to admit its applications in any important practice.

PHRYGIAN MODE. [MODE.]

PHTHALAMIC ACID. [NAPHTHALIC GROUP.]

PHTHALAMIDE. [NAPHTHALIC GROUP.]

PHTHALAMILE ($C_{16}H_4(C_{12}H_5)_2NO_4$) *Phenyltalimide.* An unimportant derivative from aniline. [NAPHTHALIC GROUP.]

PHTHALANILIC ACID. [NAPHTHALIC GROUP.]

PHTHALIC ACID. [NAPHTHALIC GROUP.]

PHTHALIDINE ($C_{16}H_9N$). An organic alcaloid, produced by the action of sulphide of ammonium upon nitrophthalene ($C_{16}H_7NO$).

PHTHALINIDE. [NAPHTHALIC GROUP.]

PHTHISIS (a Greek word, *φθίσις*, signifying "corruption," "decay") was formerly used as a generic term to signify a wasting or consumption from any cause, and was afterwards more distinctly specified, according to the organ in which it was supposed to originate: hence we had a *Phthisis hepatica*, *P. mesenterica*, *P. pulmonalis*, &c.; but the word is now restricted to the disease produced by tubercles in the lungs, and commonly known by the name of consumption. An acquaintance with this disease, from which neither age nor sex is exempt, and no part of the habitable globe is free, whose ravages extend even to the brute creation, and whose course when once begun can rarely be stayed, whose commencement is frequently so insidious, and whose termination so fatal, must, above all others, be interesting; for if by any precaution its development can be prevented, it is only by a knowledge of those influences which most frequently give rise to it that we can hope to attain our object.

Morbid Anatomy of Phthisis.—The local morbid changes peculiar to phthisis are only the result of previous changes in the general system, an hereditary or acquired predisposition, cognisable by the physical condition of the patient, and by a disordered state of various functions, "and which, though very generally accompanied with a feeble organisation, is not inconsistent with too great development and inordinate action of particular parts, and even with considerable physical power of the system." By far the most important and characteristic morbid change that occurs in phthisis consists in the development of tubercles wherever they may be found; but as it is in the lungs that they first and most frequently manifest themselves, we shall describe them as they are seen in those organs. Tubercles of the lungs first appear in the form of small, gray, semi-transparent granulations, which gradually enlarge and become opaque in their centre; the opacity increases, till the whole mass becomes of a dull yellowish-white colour. After a certain time they soften, empty themselves into the bronchial tubes, and give rise to excavations more or less considerable. In this way, almost the whole of both lungs may be invaded by a succession of tubercles, their healthy structure being absorbed as the tubercles become deposited, or involved in the destructive process consequent upon their softening. Tubercles, unlike inflammation, almost invariably commence at the summit of the lungs, where, as well as being more numerous, they are usually found in a more advanced stage of development than in any other part. The successive eruption of fresh tubercles is an important feature in this disease, as it explains the occasional recovery of patients labouring under consumption. A crop of tubercles may appear in the lungs, go through the various stages above described, and give rise to all the symptoms of confirmed phthisis; yet, provided the conditions which gave rise to them are removed, no fresh eruption may take place, and the patient may recover. The relative frequency of tubercles in other organs differs considerably in the adult and in the infant. In the former, M. Louis, our greatest authority in all matters connected with phthisis, has, with one exception, never observed them in any organ without their existing in the lungs; so that he regards their presence in these last viscera as a necessary condition for their development in other parts. But in the infant this does not appear to hold good; the bronchial glands being more frequently affected than the lungs, in the proportion of 87 to 73. The brain and its membranes are likewise more subject to tuberculous deposits in the child than in the adult. The next most important lesion which is met with in phthisis is ulceration of the intestinal canal. The ulcers may vary in number, form, and size; but they all present specific characters peculiar to this disease, and exist in five-sixths of the cases which terminate fatally. The third peculiarity in reference to phthisis is the change which the liver undergoes, to which the French pathologists have given the name of *foie gras*, or fatty liver. Lastly, ulcerations of the epiglottis, larynx, and trachea occur so frequently, and with such uniformity of type, as justly to lead to the belief that they are a part of the disease. But besides these morbid changes, which are peculiar to this disease, complications of various kinds occur which are common to it and other chronic diseases. By far the most frequent of these are inflammations of the pleuræ; so that it is extremely rare, in making the post mortem examinations of persons who die of phthisis, not to find the lungs adherent, in part or entirely, to the walls of the chest. Inflammation of the substance of the lungs is likewise a frequent complication in the latter stages of phthisis.

---

* Dr. Spurzheim and his followers constantly call upon the public to decide upon phrenology by their own observations; proving that they regard it no difficult matter to observe and draw correct conclusions in the most ambiguous questions of physiology. Upon this plan there is certainly no theory so absurd but it will easily gain adherents. One cannot feel assured that persons who are so little sensible of the difficulties of observation are themselves fully competent to observe. The more philosophic Dr. Gall did not fail to admonish his auditors not to attempt practising phrenology.

Symptoms of Phthisis.—These generally commence with a slight cough, which at first excites no attention, but is regarded as a simple cold. The breathing is not seriously affected, nor is the appetite impaired. After a time the cough increases in frequency, and is accompanied by expectoration of a clear frothy saliva; the breathing and pulse become a little hurried after meals and towards evening; and at this time of the day there is frequently experienced a slight degree of chilliness, followed by heat, which continues during the greater part of the night, and is succeeded towards morning by perspiration. The patient likewise becomes somewhat paler, and is languid and easily fatigued. In some instances, the first symptoms are preceded by a more or less copious hæmoptysis. In the second stage of phthisis the cough becomes more frequent, especially during the night; and if violent, it sometimes occasions vomiting. Hoarseness, or loss of voice, is not unusual. The expectoration changes its character; it is less frothy and more opaque; containing small particles of a yellowish-curd-like substance; or the sputa are streaked with dull-yellow lines, and hæmoptysis is pretty frequent, but in general not abundant. The breathing and pulse are more hurried; the fever is greater; and the perspirations more regular and copious. Pains in the thorax, denoting pleuritic inflammation, often occur; and the languor and emaciation still increase. In the last stage of consumption there is nearly always profuse diarrhœa, and the sweats and expectoration are more copious; the latter becomes more uniform in composition; and is separated into roundish distinct masses, with flocculent edges. The emaciation and debility keep pace with the other symptoms, and the feet and ankles swell towards evening; the appetite generally declines in the same proportion, and the patient dies in the extreme degree of marasmus, not unfrequently flattering himself to the last with a speedy recovery. In females, the menstrual discharge almost always ceases when hectic fever is established, and occasionally even before that is the case, which has led to a popular opinion that the disease in such cases arises from the suppression. Such are the ordinary symptoms presented by phthisis in its most usual form, but varieties exist in the order and duration of the morbid phenomena. Thus, tubercles may be developed in the lungs, and remain for a considerable period without exciting either cough or expectoration, or even any important general symptoms. In other cases they give rise to intense general symptoms, as fever, emaciation, anorexia, before they excite cough or expectoration, the latter appearing only a short time previous to death. To these cases the term *latent phthisis* has been applied: and what is remarkable in them is, the absence of appreciable organic alteration in organs whose functional derangement was most violent, while the only viscus really affected seems functionally healthy. The term *acute phthisis* is applied to those cases in which the disease goes through all its stages with unusual rapidity. It occurs most frequently in the young, and in those weakened by some previous disorder. In popular language it is designated "galloping consumption." *Chronic phthisis* is the reverse of the last, and comprehends all those cases in which the progress of the disease is unusually slow and generally intermittent.

Diagnosis of Phthisis.—Auscultation and percussion are the chief means by which we arrive at the diagnosis of phthisis [AUSCULTATION; PERCUSSION]; but there are several collateral circumstances which must be taken into consideration in order to form a correct opinion as to the nature of the disease. It is at the commencement of phthisis that an accurate diagnosis is of most importance, and in which the stethoscopic signs are least evident. We shall be therefore more particular in enumerating the indications at this period, than in accurately describing the acoustic phenomena which are present at a more advanced stage of the disorder. As bronchitis is the disease with which phthisis is most liable to be confounded, we shall place in juxtaposition the principal points in which they differ. In the greater number of cases of phthisis the cough comes on without any evident cause, and many months may elapse without expectoration. This apparent absence of cause and dryness of cough are of themselves very remarkable, and differ from what occurs in simple bronchitis. Thoracic pains, when present in the latter affection, are generally felt in the middle of the sternum; while in phthisis they are situated in the sides of the chest and between the shoulders. Hæmoptysis, from the commencement or during the progress of cough, is frequent in phthisis, and is almost a certain sign of the presence of tubercles; whereas this symptom never occurs in bronchitis. Out of twelve hundred patients affected with various diseases, not including cases of amenorrhœa, or those arising from external violence, M. Louis found that not one, with the exception of phthisical cases, had experienced this symptom. Auscultation gives us little or no aid in the earliest stages of phthisis; and when the stethoscopic signs first manifest themselves, they are such as result from an increased density in the structure of the lung, and not from the presence of fluid in the bronchi, as is the case in bronchitis. Thus the expiration, which in health is scarcely audible, becomes more distinct; the voice more resonant; the sound elicited on percussion duller. These alterations in the respiration, and in the signs produced by percussion, like the development of tubercles, take place from the summit to the base of the chest, and at first are almost constantly confined to the upper lobe of one side. In bronchitis the sounds result from fluid in the bronchi, and originate in the lower part of the chest, and usually on both sides. In the more advanced stage of phthisis its diagnosis is less difficult, and is made from a consideration of the sputa, which we have already described, and from the signs furnished by percussion and auscultation. These are now decisive: the upper parts of the chest are dull on percussion; the respiratory murmur is strong, coarse, or even cavernous under the clavicles; and the voice listened to in the same situation gives rise to that peculiar phenomenon termed pectoriloquy. If there should be much fluid in the lungs, resulting from the patient's not having lately expectorated, we then have a mucous rattle in all those parts of the chest corresponding with the seat of the disease; and where cavities containing fluid exist, the air passing through this produces that gurgling noise to which the term *gargouillement* has been applied by the French. The space in which these different changes take place is at first limited; but it daily increases, and in some instances, where the entire upper lobe of the lung is converted into numerous excavations, the respiration is coarse and more or less tracheal throughout its whole extent. The diagnosis of latent phthisis is not difficult, provided we make use of the proper means for ascertaining the condition of the pulmonary organs; the evil is, that the attention is directed exclusively to those functional derangements which we have spoken of when describing latent phthisis, while the real seat of the disease is overlooked.

Duration and Mortality of Phthisis.—Various circumstances affect the duration of phthisis, as age, sex, constitution, occupation, season of the year, climate, &c. In the upper ranks of life, where patients have all the advantages that a proper regimen, change of air, and good medical treatment can afford, the average duration of the disease is considerably above that in the lower classes.

The mean duration of 314 cases tabulated by MM. Louis and Bayle was 23 months, including the extreme cases; but 162, or more than half of the cases, terminated in nine months, and the greater proportion of them between the fourth and ninth month. By excluding those cases which terminate within four months, and those that exceed four years, the average duration of the remaining cases is 18 months. With regard to the mortality from phthisis, it varies in different climates, ages, sexes, races, and occupations. In England and Wales, according to the Report of the Registrar-General of Births, Deaths, and Marriages,' it is 20 per cent. of the total number of deaths, or 3·82 annually out of 1000 living. In France it is about the same. On the eastern frontiers of the Cape of Good Hope, where the atmospheric vicissitudes are sudden and great, the thermometer in summer sometimes varying from 110° to 64°, and in winter from 75° to 32°, in the course of a few hours, it is only 3½.

In cities the majority of the male labouring population is engaged in the arts, trades, and manufactures, and generally for many hours together in ill-ventilated apartments, and in unhealthy postures of body. In the country the pursuits of the same class of persons are chiefly agricultural. In respect of age, the deaths are greatest between 20 and 30, and diminish gradually to between 50 and 60, after which deaths from phthisis are comparatively unfrequent.

Causes of Phthisis.—The causes of phthisis, says Sir J. Clarke, may be divided into "the remote and the exciting, or those which induce the constitutional predisposition, and those which determine the local deposition of tuberculous matter after such predisposition is established. The one class of causes operates by modifying the whole system; the other, by determining in a system so modified the particular morbid action of which tuberculous matter is the product." Of the remote causes, or those which induce the constitutional predisposition, hereditary transmission is regarded as the most powerful; not that an individual born of consumptive parents will himself necessarily fall a prey to the same disease, but only that, when exposed to those influences which we are about to enumerate as determining the tuberculous cachexia, he will be more likely to become affected than one born of healthy parents.

At the same time it must be remembered, that with a disease so common as phthisis, a certain number of persons would be descended from phthisical parents who might contract the disease independent of hereditary descent. Dr Walshe, after the examination of 446 cases of disease phthisical and non-phthisical, came to the conclusion that "phthisis in the adult hospital population of this country is, to a slight amount only, a disease demonstrably derived from parents," and it would appear that this is generally true of the middle and upper classes of society in Great Britain.

Whatever may be the real amount of tendency to this disease given by hereditary transmission, there can be no doubt that external circumstances produce a powerful effect. Thus it is found that the death rate from phthisis is much higher for towns than it is for country districts, thus pointing to the fact that the circumstances by which persons are surrounded in towns are more favourable to the development of phthisis than in country districts. Although much may be set down to the wear and tear of a town life as compared with the country, yet when we come to examine the class of persons affected in towns, we are driven to the conclusion that one of the most powerful causes of the development of phthisis is a deficient oxygenation of the blood. It is found that in London, the deaths from phthisis amongst persons confined in shops is as 2 to 1 compared with the gentry and professional classes. Taking the trades of London, it is found that those which are sedentary favour the development of phthisis much more than those where the occupation is more active. Again, those who work in close and ill-ventilated rooms are more liable to this disease than those who work in more open and better ventilated apartments. In the case of persons who are exposed to the open air, as found by the recent parliamentary inquiry into the state of the barracks for soldiers in London, and nevertheless suffer from phthisis, it has been discovered that they sleep in close and ill-ventilated apartments. The immunity of some districts in Great Britain, as the Hebrides and north-western districts of Scotland, may be attributed to the almost perfect ventilation of the huts or cabins in which the principal part of the population resides. As an illustration of the influence of overcrowding, and the consequent elimination of the oxygenation of the tissues, the following illustration may be given. In the parish of St. James's, Westminster, there are three registration districts; in one of these 134 persons dwell upon a single acre, in a second 262, and in a third 432 persons live upon an acre. In 1858, the death from phthisis in these districts was as follows: in the first division one person in every 426 died of phthisis; in the second, one in every 422, whilst in the third and most thickly populated district, one in every 327 of the population died. There are however other conditions which lead to the same deficiency of oxygenation in the blood, and which act as occasional predisposing causes of pulmonary consumption. Such are exhausting occupations, inactivity of body, mental depression, insufficient food, and the abuse of spirituous liquors.

The more immediate or exciting causes of consumption, those which determine the deposition of tubercles, have usually been attributed to irritants acting locally on the bronchial tubes or on the lungs, whether occasioned by inflammation of these parts or by the mechanical action of irritating bodies upon them. The result of the latest investigations on this subject leave no doubt that the influence exerted in this way has been greatly exaggerated. Pneumonia and bronchitis, the two diseases hitherto regarded as the most frequent forerunners and producers of phthisis, have been shown by M. Louis to exert no more influence in its production than any other disease. They may indeed occasionally hasten the development of tubercles, but they exert no specific effect, and they act only as remote causes in impairing the health generally. These conclusions of Louis, which have been deduced from his own observations in hospital practice solely, receive ample confirmation from the admirable Statistical Reports of the Registrar-General and Major Tulloch, which we have before referred to. The popular error of attributing consumption to cold, the breaking of a blood-vessel, &c., has probably originated from mistaking the effect for the cause. We have shown in a former part of this article that cough and hæmoptysis are among the earliest symptoms of tuberculous lungs.

With regard to mechanical irritants, as dust of various kinds, noxious gases, smoke, &c., "no opinion has been more prevalent," observes Dr. Cowan, "than that those who are exposed to the inhalation of the dust of vegetable, mineral, or animal substances, are peculiarly liable to phthisis; and in the supposition that consumption was essentially a disease of the lungs, and in the great majority of instances the result of bronchial inflammation, no conclusion was more natural or more probable. But once remove from the mind the impression of a necessary connection between bronchitis and tubercles, and we feel persuaded that the examination of the evidence brought forward on the subject of dust will terminate in the conviction that this agent exerts at most but a very secondary and unimportant influence in the production of phthisis." The mortality among the workmen in some of our manufacturing towns is usually brought forward in support of the doctrine of mechanical irritation. Dr. Knight, of Sheffield, informs us that there is not an example of a polisher of forks reaching his 36th year, nor do the artisans in other departments attain a much greater age. But it must be recollected that many of these men work sixteen hours a day in a close atmosphere and confined posture of body, two conditions which contribute perhaps more than any other to the increase and production of phthisis. Nor has the mortality been diminished by the use of magnets, wire masks, currents of air, and moisture, which have been successively tried for the purpose of arresting the metallic particles. In the cases of 887 quarrymen, 557 stonecutters, and 160 marble-workers, all of them occupations involving the inhalation of dust, M. Benoiston found the proportion of phthisis was less than the general average; but then these are employments carried on in the open air. Dr. Lombard, whose researches are founded on a total of 4300 deaths from phthisis, and 54,572 individuals, exercising 220 different occupations, found, by a comparison of all the professions carried on in the open air and in workshops, that the proportion of deaths from phthisis was *double* among the latter; and this proportion increased as the apartments were close, narrow, and imperfectly ventilated.

Mr. Watson, a surgeon of Wenlockhead, a mining district, informs us that, out of 74 men working during four or five months for sixteen hours daily in a mine where a candle burnt with difficulty, not one was attacked with any pulmonary affection. But whether from the inhalation of any noxious gases or from other causes, it is certain that in the majority of the mining districts of this country the mortality from phthisis is high. The number of males attacked by this disease in Cornwall exceeds that of the females in the ratio of 170 to 140, and in the mining parts of Staffordshire, Shropshire, and Worcester, in the ratio of 203 to 191; while in the non-mining districts of Staffordshire and Shropshire, and in the county of Cheshire, the ratio is 656 males to 796 females.

The influence of smoke, when uncombined with other agents of injurious tendency, may, we think, fairly be called in question. In Leeds, which is certainly the most smoky place in the whole kingdom, the mortality of females from phthisis is below that of most of our large manufacturing towns, and is not much above the average for the whole of England and Wales. In London likewise this is the case, and in nearly the same proportion.

A moist and changeable climate was long regarded as among the most active causes of consumption; and Great Britain, whose climate combines these two conditions in a remarkable degree, has been looked upon as such a nursery for phthisis, that our facetious neighbours on the other side of the Channel have styled it "La Maladie Anglaise." Indeed the notions of atmospheric vicissitudes, dampness, and consumption, seem almost inseparable. However, these opinions have been and still are undergoing a severe scrutiny; and the evidence which we at present possess on the subject tends very strongly to disprove their correctness. Moisture and climate, like all other agents, act either locally or generally; popular belief has attributed their presumed prejudicial effects to local action. They tend, it is said, to produce catarrhs and coughs, and consequently consumption. We need scarcely allude again to the fallacy of this opinion. We are in possession of little information on the mode in which climate operates to the production of phthisis. That the disease prevails to a much greater extent in some climes and localities than in others, is an indisputable fact; but it is no less certain that its prevalence is not confined to countries of variable temperature, for many of such countries suffer in a much less degree than those whose thermometric range varies little throughout the year. Is phthisis contagious? This is a question which has been often discussed, and numerous are the testimonies both (when we consider the relations of heat and light, thus taken together to the other physical forces) that they in reality are the initiating forces of nature, and that when they seem to be produced by the other forces, they are, in fact, merely evolved from them. Much evidence might be adduced from natural phenomena, and the results of experimental research, in favour of this view of the subject. But heat and, light appear to have the power of producing the other forces from the moment of their own origination; and the broad induction from the actual state of our knowledge of their radiation is that they originate in union, and—in an absolute sense—are inseparable, both being always present, though in variable proportions to each other; with, at the same time, a certain reciprocity of presence and activity, the one taking the place of the other to the extent, or in the degree, to or in which the other is absent. The recent experimental researches on radiation of M. Foucault, Mr. Balfour Stewart, and Professor Kirchhoff ('Proc. of Roy. Soc.,' and 'Phil. Mag.,' 1860, &c.), seem to furnish irrefragable evidence on this point; and a remarkable example of the reciprocity here alluded to, in the relation of animal heat and animal light to each other, was pointed out by Mr. Brayley, in a lecture delivered at the London Institution in 1833, the substance of which was communicated to the Natural History section of the British Association in that year, but not printed till 1835, when it appeared in 'Phil. Mag.,' third series, vol. vi. pp. 241-247.

Electricity is characterised by the author of the theory of the correlation of physical forces, "as that affection of matter or mode of force which most distinctly and beautifully relates other modes of force, and exhibits, to a great extent in a quantitative form, its own relation with them, and their reciprocal relations with it and with each other." Commencing with it as an initiating force, we get motion directly produced by it, in various forms; for instance, in the attraction and repulsion of bodies,[*] and in the deflection of the galvanometer needle. Electricity directly produces *heat*, as shown in the ignited wire, the electric spark, and the voltaic arc. In these phenomena, also, it directly produces *light*, of the greatest known intensity. It directly produces *magnetism*, as originally shown by Oersted in his great discovery [ELECTRO-MAGNETISM]. Lastly, electricity produces *chemical affinity*; and by its agency we are enabled to obtain effects of analysis or synthesis with which ordinary chemistry does not furnish us.

Light is, perhaps, that mode of force the reciprocal relations of which with the others have been the least traced out. Until the discoveries of Niepce, Daguerre, and Talbot [PHOTOGRAPHY], very little could be definitely predicated of the action of light in producing other modes of force. Viewing the phenomena of photography as resulting from a function of light, we get the latter as an initiating force, capable of producing, mediately or immediately, the other modes of force. Thus, it immediately produces chemical action; and having this, we at once acquire a means of producing the others. In Mr. Grove's lectures at the London Institution in 1843, already mentioned, he showed the following experiment by which the production of all the other modes of force by light is exhibited. "A prepared daguerreotype plate is enclosed in a box filled with water, having a glass front, with a shutter over it. Between this glass and the plate is a gridiron of silver wire; the plate is connected with one extremity of a galvanometer coil, and the gridiron of wire with one extremity of a Breguet's helix: the other extremities of the galvanometer and helix are connected by a wire, and the needles brought to zero. As soon as a beam of either daylight or the oxyhydrogen light is, by raising the shutter, permitted to impinge upon the plate, the needles are deflected. Thus, light being the initiating force, we get *chemical action* on the plate, *electricity* circulating through the wires, *magnetism* in the coil, *heat* in the helix, and *motion* in the needles."

Light would seem directly to produce heat in the phenomena of what is termed absorption of light. Whenever light is absorbed heat takes its place, affording us apparently an instance of the conversion of light into heat; and of the fact, that the force of light is not, in reality absorbed or annihilated, but merely changed in character, becoming in this instance converted into heat by impinging on solid matter, as heat is converted into light when solid incombustible matter becomes intensely luminous by being introduced into highly-heated but only slightly luminous gas. The difference between the correlation of light and heat and that of the other forces with each other, and with them, has already been noticed, and will also be returned to in the sequel.

Magnetism, as was proved by the important discovery of Faraday [MAGNETO-ELECTRICITY], will produce *electricity*, but with this peculiarity, that in itself it is static; and, therefore, to produce a dynamic force, motion must be superadded to it; it is in fact directive, not motive, altering the direction of other forces, but not in strictness initiating them. Magnets being moved in the direction of lines joining their poles, produce electrical currents in such neighbouring bodies as are conductors of electricity, in directions transverse to the line of motion. So if the magnet be stationary, conducting bodies moved across any of the lines of magnetic force have currents of electricity developed in them. Magnetism can, then, through the medium of electricity, produce *heat*, *light*, *chemical affinity*, and *motion*. It can itself be produced by these forces, but cannot produce them except when in motion, which, therefore, is to be regarded in this case as the initiative force. Magnetism will, however, directly affect the other forces, light, heat, and chemical affinity, and change their direction or mode of action, or, at all events, will so affect matter subjected to these forces that their direction is changed. When this force, however, is in what may be called its dynamic condition, that is, its state of change at the commencement and the termination, or during the increment or decrement of its development, it will produce directly some of the other forces, electricity and heat for example. "But it may be said," observes Mr. Grove on this point,—and the observation is important with reference to the philosophy of the entire subject of the correlation of physical forces,—"while magnetism is thus progressive some other force is acting on it, and therefore it does not initiate." This he admits to be true, but urges that "the same may be said of all the other forces; they have no commencement that we can trace. We must ever refer them back to some antecedent force equal in amount to that produced, and therefore the word initiation cannot in strictness apply, but must only be taken as signifying the force selected as the first." The peculiarity, however, of the mutual relations of heat and light, already noticed, as recognised by Mr. Grove himself, points, as remarked above, to a limitation of the truth of his views in this respect.

Chemical affinity, or the force by which dissimilar bodies tend to unite and form compounds differing generally in character from their constituents, will directly produce *motion* of definite masses, by the resultant of the molecular changes it induces, of which the projectile effects of gunpowder are familiar instances. By chemical affinity, again, we can directly produce *electricity*, and through its medium it may be quantitatively converted into the other modes of force: but *heat* and *light* are immediate products of chemical affinity, and chemical action produces *magnetism* whenever it is thrown into a definite direction, as in the phenomenon of electrolysis, a simple instance of which Mr. Grove adduces as presented by his gas voltaic battery. This completes the review of the phenomena arising from the correlation of the physical forces, each taken in turn as the initiating one.

Mr. Grove states his belief that the same principles and mode of reasoning as have been adopted in his Essay, might be applied to the organic as well as the inorganic world; and that muscular force, animal and vegetable heat, &c., might, and at some time will, be shown to have similar definite correlations; but that he has purposely avoided this subject, as pertaining to a department of science to which he has not devoted his attention. He alludes, however, to the experiments of Professor Matteuci, by which it appears that whatever mode of force it be which is propagated along the nervous filaments, that mode of force is definitely affected by currents of electricity; and he states, also, that by an application of the doctrine of the correlation of forces, Dr. Carpenter has shown how a difficulty arising from the ordinary notions of the development of an organised being from its germ-cell may be lessened.

In the 'Philosophical Transactions' for 1850, pp. 727-757, is a valuable paper by Dr. Carpenter 'On the Mutual Relations of the Vital and Physical Forces,' in which the principle of the correlation of the latter is successfully extended in some detail to the former, the subject of the germ-cell considered, as just alluded to, and, the view of the correlation of the nervous and electrical forces, in particular, which had been proposed by Dr. Carpenter some years before, and had been afterwards formally adopted by Professor Matteuci, fully established. In this paper, perhaps the most important general enunciation on the subject of correlation which has followed Mr. Grove's 'Essay,' and certainly the first, of an adequately definite and comprehensive nature, on the application of the doctrine to the phenomena of organisation, the author states, that he "is not aware that any other attempt has been made to *formularise* the entire series of these mutual relations, [the 'very intimate mutual relations' of the physical forces] than that which has been put forth by Professor Grove in his short treatise 'On the Correlation,' &c." But Mr. Grove, we must here remark, did much more than merely formularise these relations. He announced a new conception of their nature, which logically speaking, is a *universal* of physics, and this it is which gives his enunciation its true value, and elevates it almost to the rank of a discovery. Another of Dr. Carpenter's introductory remarks concerns "a point on which," he says, "Professor Grove has not thought it requisite strongly to dwell; namely, the necessity for a certain *material substratum* as the medium" of the conversion of force. The existence, however, of that substratum is a necessary implication of Mr. Grove's entire doctrine. As he considers all the physical forces to be intrinsically affections of matter, understanding that term (to use the language of philosophical criticism) in its vulgar sense,—the necessity in question is an inseparable element of his theory, and is therefore virtually dwelt upon throughout his Essay.

---

[*] It follows as a consequence of the doctrine of the correlation of forces, that when electricity performs any mechanical work which does not return to the machine, electrical power is lost, having been converted into mechanical force. In a discourse 'On Inferences from the Negation of Perpetual Motion,' delivered June 25, 1856, Mr. Grove performed an experiment in which this loss was rendered evident. The acknowledged truth of the impossibility of perpetual motion is applied, deductively, in this discourse, to verify the doctrine of correlation. ('Proc. of the Royal Institution,' pp. 152–159.)

Dr. Carpenter has lately (Feb. 24, 1860) returned to this subject, in a discourse delivered at the Royal Institution, and printed in the 'Proceedings' at the meetings of the members, vol. iii., pp. 206-209, 'On the Relation of the Vital to the Physical Forces.' He argues, that when we carefully look into the question, we find that what the *germ* really supplies is not the *force* but the *directive* agency. This agency may be regarded, he observes, like magnetism, as a *static* force; and just as magnetism requires to be (as we have already seen from Mr. Grove) combined with motion to enable it to develope electricity, so does the directive agency of the germ need the co-operation of a *dynamic* force for the manifestation of its organising power. That dynamic force is heat, the influence of which upon the rate of growth and development, both animal and vegetable, is so marked as to have universally attracted the attention of physiologists, who, however, have only recognised in it a *vital stimulus*, calling forth the latent power of the germ, instead of looking upon it as itself furnishing the power that does the work. It is indeed only when the physiological survey is extended from the vital phenomena of warm-blooded animals to those of cold-blooded animals and of plants, that the immediate and direct relation between heat and vital energy, as manifested in the rate of growth and development, or of other changes peculiar to the living body, is unmistakeably manifested. "Hence," Dr. Carpenter concludes, after summarily reviewing the phenomena of vegetable life under this point of view, "we seem justified in affirming that the correlation between heat and the vital force of plants is not less intimate than that which exists between heat and motion. The special attribute of the vegetable germ is its power of effecting the metamorphosis, and of utilising the organising force according to the plan of construction characteristic of each species."

For the details of Mr. Grove's own illustrations and applications of his doctrine, we must refer to his work itself, in which, also, are given his views of the intrinsic nature of the physical forces; views which are inseparable, in his opinion, from the dogma of their correlation. In this, however, we cannot agree with him. That dogma, we conceive, will remain a concrete expression of the truth, as a *first approximation* of great generality, and in point of time *the* first approximation to a general theory, whatever notion may be finally established of the nature of the forces concerned, and whether heat, for instance, be regarded as a motion of the particles of ordinary matter—that is of the matter exhibiting its phenomena—or as a motion of a calorific ether pervading that matter. This discrimination we believe will be found important in the further application and investigation of the subject. In the article GROVE, WILLIAM ROBERT, in the BIOGRAPHICAL DIVISION of this work, some remarks relevant on this head, have been offered with respect to the history and interpretation of the principle of the Correlation of Physical Forces, to which we may now refer as completing, together with the present and following remarks, our view of the subject.

Dr. Faraday's brilliant series of discoveries respecting the forces of nature, and their relations to each other and to matter,—of which Volta's discovery of the pile, Davy's application of it to electrolysis, Oersted's discovery of electro-magnetism, Seebeck's of thermo-electricity, Tyndall's of the relation to structural density of para- and dia-magnetism, and Mr. Grove's own discovery of the gas-battery, may be cited as parallels of single terms in that series,—have probably contributed more than those of any other experimental philosopher to prepare the scientific public mind for the idea of correlation; and they have had this effect, not only on account of their aggregate magnitude, as constituting so great a part of the advance in physics made during the last sixty years, but because, from their bearing so extensively on what Dr. Faraday calls "the dual forms of power," electricity and magnetism, they have exhibited both the actuality of physical correlation, and the convertibility of force, in a manner so palpably intelligible. In the relations subsisting between positive and negative electricity, and north and south magnetism, respectively, we have the mental idea of correlation realised to sensible perception. The relation of those forces themselves is probably a not less perfect correlation, though perhaps of a different order; while their mutual convertibility, in which electro-magnetism and magneto-electricity originate, is so readily demonstrated by experiment.

In an addition (June, 1858) to his discourse on the "Conservation of Force," (a designation introduced we believe by Helmholz, in advocating a principle long tacitly admitted in particular cases, but which had not before been explicitly recognised in its true generality,) delivered in the preceding year (Exp. Res. in Chem. and Phys. p. 461-462), Dr. Faraday says—"Those who admit the possibility of the common origin of all physical force, and also acknowledge the principle of conservation, apply that principle to the sum total of the force. Though the amount of mechanical force (using habitual language for convenience sake) may remain unchanged and definite in its character for a long time, yet when, as in the collision of two equal inelastic bodies, it appears to be lost, they find it in the form of heat, and whether they admit that heat to be a continued mechanical action (as is most probable), or assume some other idea, as that of electricity, or action of a heat-fluid, still they hold to the principle of conservation by admitting that the sum of force, that is, of the 'cause of action,' is the same, whatever character the effects assume. With them the convertibility of heat, electricity, magnetism, chemical action, and motion, is a familiar thought." This is forcibly put, and is perfectly true; but the mutual convertibility of the forces enumerated has only become "a familiar thought" since Mr. Grove's announcement of the principle of their correlation. No one, however, could have more perfectly realised the conception of that principle, or appreciated its importance, than Dr. Faraday, as indeed the preceding extract may itself show. The latest course of lectures delivered by him (and published in the 'Chemical News') consisted of 'Illustrations of the Various Forces of Matter,—*i. e.*, of such as are called the Physical or Inorganic Forces, including an Account of their Relations to each other.' The subject of the concluding lecture, given on the 7th of January last (1860), was, *eo nomine*, 'The Correlation of the Physical Forces,' of which many experimental demonstrations were shown, relating chiefly to the change of chemical force into electricity, and of electricity into magnetism; and this eminent explorator of physical truth, observing to his audience that he might show them many other experiments by which he could obtain electricity and chemical action, heat and light from a magnet, terminated his course by the emphatic question, "But what more need I show you to prove the universal correlation of the physical forces of matter, and their mutual conversion one into another!"

A certain amount of anticipation of Mr. Grove's views has been recently claimed by Professor Tyndall ('Glaciers of the Alps,' p. 300) for the late M. Rendu, bishop of Annecy, the author of a remarkable essay on glaciers, published in 1841. In considering what he calls the "law of circulation," and after alluding to the circulation of water through terrestrial nature, and that of the elements of organic substances from the solid to the fluid, and thence again to the state of organisation, M. Rendu adds, "That universal agent which we designate by the names fire, light, electricity and magnetism, has probably also a *circulation* as wide as the universe." But this is exactly one of those comparatively vague notions, however true in their degree, referring the forces of nature to a common principle, which have been alluded to in the introductory part of this article, and to which every period in the history of philosophy, for at least a century before, supplies a parallel. When Professor Tyndall in sequence claims also for Rendu, on the same account, a degree of anticipation of Helmholz's more recent doctrine of the 'Conservation of Force,' quoting the latter as saying in reference to the "circuit" formed by "heat, light, electricity, magnetism, and chemical affinity," "starting from each of these different manifestations of natural forces, we can set every other in action," he ascribes to Helmholz what had before been explicitly enunciated by Grove, almost in the same words, as may be seen in the preceding statement of his doctrine.

Dr. (late Professor) James D. Forbes ('Reply to Tyndall on Rendu') has already noticed the futility of these claims; but what he, by the free application of *meiosis*, calls "the theoretical inferences of Messrs. Grove and Helmholz," Faraday, as we have seen, accepts as demonstrated principles of nature, and Professor Le Conte, we shall presently find, regards as forming "a necessary truth," and "one of the grandest generalisations in modern science."

Two remarkable circumstances have characterised the history of the reception of Mr. Grove's doctrine of correlation. Many physicists and others who admit in a general manner the principle, seem very unwilling to use the term; while others who explicitly adopt and advocate both, seem equally unwilling to ascribe them to their author, and omit all reference to him.

Thus, in Professor Liebig's 'Familar Letters on Chemistry' (1858), in the preface to the fourth edition, the introduction of a letter (the 13th) 'On the Correlation of the Forces of Inorganic Nature,' is announced in the preface, but neither in that nor in the letter itself is Mr. Grove mentioned, nor indeed are his views given, though his designation of the subject is thus unreservedly employed. It is applied, in the letter, chiefly to a view of natural forces taken by Dr. Mayer of Heilbronn, asserting both their indestructibility and their convertibility, as consequences of the axiom *Causa æquat effectum*, but not dated, and apparently subsequent to the views both of Helmholz and of Grove.

The following introductory paragraph of an excellent paper by Professor Le Conte, of South Carolina College, Columbia, U. S., 'On the Correlation of Physical, Chemical, and Vital Force, and the Conservation of Force in Vital Phenomena,' contains one of the most emphatic and adequate recognitions of the importance of those principles and intelligible terse statements of their nature which has yet appeared; though, even in this, no allusion is made either to Mr. Grove or to M. Helmholz, and the uninformed reader might be led to suppose that being necessary truths they had always been self-evident. "Matter constantly changes its form, but is itself indestructible, except by the same power which called it into being. The same quantity of matter exists in the universe at all times. So also force changes its form constantly, but is itself indestructible, incapable of increase or diminution, and the same absolute amount of force exists in the universe at all times and for ever. The mutual convertibility of the various forms of force is called 'correlation of forces.' The invariability of the absolute amount in the midst of constant change is called 'conservation of force.' This principle of correlation and conservation of force must be looked upon as one of the grandest generalisations in modern science,—a principle startling at first, but when clearly understood and firmly grasped, almost axiomatic. It must be considered a necessary truth, and, as such, is a legitimate basis of deductive reasoning. The correlation of physical forces is universally recognised as a principle in science, and not only so, but has already been productive of many beautiful and useful results." For Professor Le Conte's application of the principle to the history of organic nature, we must refer to the paper itself. 'Amer. Journ. of Science,' Nov. 1859, reprinted in 'Phil. Mag. Fourth Series,' vol. xix., p. 133.

Again, in the introductory address delivered on the opening of St. Thomas's Hospital Medical College, Southwark, London, on the 1st of the present month (October, 1860) by Mr. R. D. Grainger, F.R.S., which has the emphasis of being also a valedictory address on his retirement from the chair of physiology in that school, we find the following passages, which are here cited, not merely for the purpose of claiming for Mr. Grove what of right belongs to him, but because we have in them the sentiments of an eminent physiologist on the correlation of the vital and physical forces. "In the case of the forces implicated respectively in inorganic and organised bodies, it may in the present state of knowledge be very difficult to demonstrate their ultimate identity. Nor need this be a matter of surprise when we recollect how very recently the intimate relations of the several physical forces themselves have been discovered by such researches as those of Oersted, Faraday, and Graham. Chemical force, electricity, magnetism, caloric, and light, act and react on each other in the mode signified by the term correlation, and are probably, as many profound philosophers suppose, only different manifestations of one universal all-prevading force." Proceeding next to the organic forces, the experiments of Matteuci on the nervous and muscular forces are noticed, together with Dr. Todd's proof that the latter is not itself electricity, the evidence of which is stated to be afforded by "phenomena the very counterpart of what Professor Müller pointed out years ago, in regard to the nervous and electric forces." "Now, although," Mr. Grainger continues, "this may seem to indicate an ultimate and essential difference between the electric and muscular currents, it presents the very same condition of things as that expressed by the term 'correlation of forces.'" Farther on he alludes to the maxim, that there is no creation of force, observing that "no force is ever manifested without an equivalent change of matter, which change, according to the wide generalisation of one of our former colleagues, my friend, Dr. Leeson, is in every form—light, electricity, magnetism, gravitation, &c.—ultimately resolvable into motion." 'Lancet,' 1860, vol. ii. p. 352, 353.

Whether Dr. Leeson's generalisation was enunciated prior to Mr. Grove's we are not aware; but it is simply one elementary correlation of the latter. The reader will have observed that while the doctrine, as well as the designation, of the correlation of forces is fully adopted, Mr. Grove's name is not mentioned; nor does it occur anywhere in Mr. Grainger's address.

We have endeavoured in this article to do justice to Mr. Grove, and to the subject to which he has devoted so much attention and thought. The progress of science, in its approach to the abstract truth, consists partly in the ascent to higher and higher generalisations successively, and partly in the limitation of generalisations previously attained, or, in other words, the verification of hypotheses. Fully believing the doctrine of the correlation of physical forces, we stated several years since our opinion that that doctrine is the expression of the deeper or higher truth, that they are all, not excluding mechanical force, effects, or affections, of the ether,—the ether of Hooke, Young, and Fresnel, and generally of the mathematicians and physicists who have advocated the undulatory theory of light and of heat. In the 'Philosophical Magazine' for January, 1859, Professor Challis of Cambridge, thus introduces his theory of the principle:—"It appears to be established by modern experimental researches, that the different physical forces are mutually related by some common condition, or bond of connexion; but what the precise nature of the connexion is, perhaps experiment alone is incapable of determining. This generalisation will become matter of exact knowledge only when it is brought within the domain of mathematics. The great desideratum of the existing state of natural philosophy is a *mathematical theory of physical forces.* After the explanations that have been given of a great variety of the phenomena of light, which is one of those forces, by the hypothesis of a highly elastic medium pervading space, it is not a little surprising that an explanation of the '*correlation*' of the several forces should not have been sought for in the existence of this medium, which would seem to be a vast reservoir of force sufficient to account for all observed dynamical effects." Professor Challis has pursued this subject in a series of elaborate analytical investigations, also published in the 'Philosophical Magazine' for 1859 and 1860. "The principal hypothesis of the theory is, that the physical forces are all consequences of the motions and pressures of a uniform and highly elastic medium pervading space. The variations of the pressures of the medium are supposed to be proportional to variations of its density; and this supposition forms the basis of a mathematical investigation of the relations between the motions and the pressures. Further, it is assumed that the medium acts immediately by pressure on the ultimate atoms of bodies, which are all supposed to be spheres of invariable magnitudes and of the same intrinsic inertia. According to those hypotheses, the different phenomena and properties of bodies depend only on the *magnitudes* of their atoms, the *proportions* in which they are composed of atoms of *different* magnitudes, and on the *arrangements* of the atoms." As the explanation of the sensible properties of matter must be preceded by a mathematical investigation of the laws of the dynamic action of the assumed etherial medium, Professor Challis has already entered on such an investigation relatively to light, heat, the force of gravity, the forces of molecular aggregation, and the force of electricity; and is still proceeding with the explanation of his theory.

We will conclude this article by the suggestion that progress in natural philosophy, in both the directions indicated above, would probably be effected by the experimental and mathematical investigation of the following theorem:

Taking *space* to be the extension of material substance, the resultant of its dimensions, and mere consequence of its existence; and *motion* to be the substitution of one portion of matter for another, identical with the succession of phenomena, our perception of which is *time:* heat and light are correlates of each other, being also, as we receive them from the sun, and as existing in their terrestrial form, affections of an ether pervading space and ordinary ponderable matter; but acting as the initiating forces in respect of electricity, magnetism, and chemical affinity, which are correlates of each other of a different order, and derivative affections of the ether (perhaps, also, derivatively from the ether, of the matter exhibiting their phenomena), the apparent production of heat and light by them being in reality the *evolution* only of those initiating forces: all these forces have the power of substituting one portion of matter for another, or of causing motion; the apparent agency of time and motion being merely the continuance and consequent accumulation of action.

PHYSICIAN (ὁ φυσικός), a word derived from *φύσις*, *nature*, which meant originally what we should now call a *natural philosopher*, or one of those persons who have for their object the investigation of nature and its laws, in opposition to *οἱ ἠθικοί*, or those who examine particularly into the moral nature of men. [PHILOSOPHY.] In English however the word *physician* is used only to designate the professors of the healing art, called in Greek *ἰατροὶ*, and in Latin *medici;* while in most (if not all) other European lanaguages the derivatives of the Greek word are still employed in their original meaning, and the idea of *healing* is expressed either by some native word or by one derived from the Latin.* The origin and progress of physic, together with an account of the different medical sects, has been given already under MEDICINE; in the present article it is proposed to mention some of the most curious and interesting facts respecting the rank, education, &c., of the physicians of antiquity, and afterwards to state the legal qualifications for practising this branch of the medical profession in our own country.

In Greece and Asia Minor the profession of medicine seems to have been held in high esteem, for, not to mention the apotheosis of Æsculapius, who was considered as the father of it, there was a law at Athens that no female or *slave* should practise it (Hyginus, 'Fab.,' cap. 274); Ælian mentions one of the laws of Zaleucus among the Epizephyrian Locrians, by which it was ordered that if any one during his illness should drink wine contrary to the orders of his physician, even if he should recover, he should be put to death for his disobedience ('Var. Hist.,' lib. ii., cap. 37); and there are extant several medals struck by the people of Smyrna in honour of different persons belonging to the medical profession. (Mead's 'Dissertatio de Nummis quibusdam à Smyrnæis in Medicorum Honorem percussis,' 4to., Lond. 1724.) If the Decree of the Athenians (published among the letters of Hippocrates) be genuine, and if Soranus ('in Vitâ Hippocr.') can be depended on, the same honours were conferred upon that physician as had before been given to Hercules; he was voted a golden crown, publicly initiated into the Eleusinian mysteries, and maintained in the Prytaneum at the state's expense. (See also Pliny, 'Hist. Nat.,' lib. vii., cap. 37.) Some idea of the income of a physician in those times may be formed from the fact mentioned by Herodotus (lib. iii., cap. 131), that the Æginetans (about the year B.C. 532, Ol. 62, 1) paid Democedes from the public treasury one talent per annum for his services, that is (if we reckon, with Hussey, 'Antient Weights and Money, &c.' the Æginetan drachma to be worth 1*s.* 1¾*d.*), not quite three hundred and forty-four pounds; he afterwards received from the Athenians one hundred minæ, that is (reckoning, with Hussey, the Attic drachma to be worth 9¾*d.*), rather more than four hundred and six pounds; and he was finally attracted to Samos by being offered by Polycrates a salary of two talents, that is (if the Attic standard be meant) four hundred and eighty-seven pounds ten shillings. It should however be added that Valckenaer doubts the accuracy of this statement of Herodotus with respect to the Æginetans and Athenians (and apparently with reason), on the ground that the latter people, at the time of their greatest wealth, only allowed their ambassadors two drachmæ (or 1*s.* 7½*d*) per day, that is, somewhat less than thirty pounds per annum. (Aristoph., 'Acharn.,' v. 66.) It seems to have been not uncommon in those times (as afterwards in the later Roman empire, see ARCHIATER in BIOG. DIV.), for states to maintain physicians, who were paid at the public cost (Xenophon, 'Memor. Socr.,' lib. iv., cap. 2, § 5; Plato, 'Gorg.,' § 23; Strabo, lib. iv., p. 125; Diod. Sic., lib. xii., cap. 13); and these again had attendants, for the most part slaves, who exercised their calling among people of low condition. (Plato, 'De Leg.,' lib. iv., p. 720, ed. Steph.; Boeckh's 'Public Econ. of Athens,' vol. i., p. 160.)

---

* Somewhat analogous to this is the use of the Arabic word *hakim* (from *hakama*, 'novit' 'sapiens fuit') which properly means *a wise* or *learned man* in general, but is very frequently used in a restricted sense to signify *a physician.*

In the earlier times of the Roman republic physicians were unknown (Pliny, 'Hist. Nat.,' lib. xxix., cap. 5, ed. Tauchn.); and for some time afterwards the exercise of the profession was in a great measure confined to persons of servile rank; for the richer families having slaves who were skilled in all sorts of trades, &c., generally possessed one or more that understood medicine and surgery. (Middleton's Essay 'De Medicorum apud Romanos degentium Conditione,' Cantab., 1726, 4to., and the various answers to it that appeared on its publication.) To this practice however there were many exceptions; namely, the physician who was taken prisoner with Julius Cæsar by the pirates at the island of Pharmacusa (Sueton., cap. 4), and who is called his friend by Plutarch (see Casaubon's Note on Sueton.); Archagathus, who, being the first foreign surgeon that settled at Rome, had a shop bought for him at the public expense, and was presented with the Jus Quiritium, A.U.C. 535, B.C. 219 (Cassius Hemina ap. Pliny, 'Hist. Nat.,' lib. xxix., cap. 6); Artorius, who is known to have been a physician (Cæl. Aurel. 'De Morb. Acut.,' lib. iii., cap. 14, p. 224), and who is called the friend of Augustus (Plutarch, 'Vita Bruti,' cap. 41, ed. Tauchn., where however it should be noticed that some editions read *'Αντώνιος,* instead of *'Αρτώριος*); Asclapo, whom Cicero calls his friend ('Epist. ad Divers.,' lib. xiii., ep. 20); Asclepiades, the friend of Crassus the orator (Cic. 'de Orat.,' lib. i., cap. 14); Eudemus, who is called by Tacitus ('Annal.,' lib. iv., cap. 3) the friend and physician of Livia; and others. With respect to the income made by eminent physicians at the beginning of the Roman empire, we learn from Pliny ('Hist. Nat.,' lib. xxix., cap. 5) that Albutius, Arruntius, Calpetanus, Cassius, and Rubrius gained two hundred and fifty thousand sesterces per annum, that is (reckoning with Hussey the mille nummi (*sestertium*) to be worth, before the reign of Augustus, 8*l.* 17*s.* 1*d.*) about two thousand two hundred and thirteen pounds ten shillings; that Quintus Stertinius made it a favour that he was content to receive from the emperor five hundred thousand sesterces per annum (or rather more than four thousand four hundred and twenty-seven pounds), as he might have made six hundred thousand sesterces (or five thousand three hundred and twelve pounds ten shillings) by his private practice; and that he and his brother, who received the same annual income from the emperor Claudius, left between them at their death, notwithstanding large sums that they had spent in beautifying the city of Naples, the sum of thirty millions of sesterces (or two hundred and sixty-five thousand six hundred and twenty-five pounds). Of the previous medical education necessary to qualify a physician for the legal practice of his profession in the early times, we know nothing; afterwards however this was under the superintendence of the Archiatri. [ARCHIATER.]

Among the Arabians the medical profession appears to have been held in high esteem. Many of their chief physicians were Jews or Christians, and some apostatised to Mohammedanism: in some families the profession would seem to have been in a manner hereditary, as in that of Avenzoar (*Ibn Zohir*), five of whom successively belonged to it. (Reiske's 'Abulfedæ Annal. Moslem.,' tom. iv., p. 669.) The qualifications necessary for practising medicine seem to have been rather slight, till the Caliph Moctader, A.H. 319 (A.D. 931), in consequence of an ignorant practitioner's having killed one of his patients, passed a law that no one should be allowed to practise until he had been licensed to do so by the chief physician. (Casiri, 'Biblioth. Arabico-Hisp. Escur.,' tom. i., p. 438.) Some idea of the consideration in which the Arabic and Moorish physicians were held may be gained from the fact that Sancho the Fat, king of Leon, was obliged to go in person to Cordova, A.D. 956 (A.H. 345), to be cured of an illness. ('Mariana,' l. viii. c. 7, tom. i., p. 318; Conde, 'Domin. des Arabes,' &c., t. i., p. 448.)

The first medical school that was established in Europe was that at Salerno (Salernitana Schola) towards the end of the 7th century; the second was probably that at Montpelier, founded about a hundred years afterwards: their course of medical education is unknown, but they doubtless excercised a most beneficial influence on the acquirements, and therefore on the personal rank and consideration of the physicians of the age. For a long time however the profession of medicine was almost entirely confined to the clergy, who indeed were the only persons in those days that possessed any share of learning. Surgery was however given up to the laity, as the clergy were prohibited from undertaking any bloody operation.

Hence arose the distinction of the three regular orders of the medical profession, namely, physicians, surgeons, and apothecaries; and it is to the first of these exclusively that the remainder of this article will be dedicated. The degree of bachelor of physic seems to have been known at Oxford soon after the Conquest; and in the 14th century we find that the degree of doctor of physic was by no means uncommon. (Wood's 'Hist. of Oxford,' vol. ii., p. 765, ed. Gutch; Chaucer's 'Doctor of Physic's Tale.') The English colleges could not of their own authority prevent any from undertaking to practise, though they had not obtained a degree in physic. On this account therefore, in the ninth year of the reign of Henry V., 1422, our universities proposed that an act of parliament should be passed ordering that "No one shall use the mystery of physic unless he hath studied it in some university, and is at least a bachelor in that science. The sheriff shall inquire if any one practises in his county contrary to this regulation; and if any one so practise, he shall forfeit 40*l.* and be imprisoned: and any woman who shall practise physic shall incur the same penalty." (Quoted in Willcock, 'On the Laws of the Medical Profession,' part ii., p. iii.)

This measure had not however the desired effect; indeed there appears to be some doubt whether it ever obtained the force of an act of parliament, on account of its being referred to the privy council for confirmation. In the third year of the reign of Henry VIII., 1511, was passed an act, which is generally received as the first operative law on the subject, and which takes no notice of the supposed statute of Henry V. By this, which is especially aimed against the sorcerers, witches, and smiths, "who can no letters on the book," it is enacted that "no person within the city of London, nor within seven miles of the same shall take upon him to exercise or occupy as a physician, except he be first examined, approved, and admitted by the bishop of London, or by the dean of St. Paul's, for the time being, calling to him or them four doctors of physic; upon the pain of forfeiture, for every month that they do occupy as physicians not admitted nor examined after the tenour of this act, of 5*l.*," &c. &c. After making the same enactment for the different counties, the act goes on to say, "Provided always, that this act nor anything therein contained be prejudicial to the universities of Oxford and Cambridge, or either of them, or to any privileges granted to them." (Willcock, pp. 6, 7; Goodall's 'Hist. of the Col. of Physicians,' p. 1-3.)

In the fourteenth year of the same reign, 1522, another act was passed, by which the examination of physicians was taken from the persons appointed for that purpose by the former statute, and reposed in the college instituted by a charter of that king. [PHYSICIANS, COLLEGE OF.] Under this the university graduates who might desire to practise in London were included, as well as the other physicians; and since that time the legislature has seldom interfered on the subject.

With respect to the present state of the profession, the first class of medical practitioners in rank and legal pre-eminence is that of the physicians. They are (by statute 32 Henry VIII.) allowed to practise physic in all its branches, among which surgery is enumerated. The law therefore permits them both to prescribe and compound their medicines, and to perform operations in surgery as well as to superintend them. These privileges are also reserved to them by the statutes and charters relating to the surgeons and the apothecaries. [SURGEON.] Yet custom has more decidedly distinguished the classes of the profession, and assigned to each its peculiar avocations. The practice of the physician is universally understood, as well by their college as the public, to be properly confined to the prescribing of medicines, which are to be compounded by the apothecaries; and in so far superintending the proceedings of the surgeon as to aid his operations by prescribing what is necessary to the general health of the patient, and for the purpose of counteracting any internal disease. It would be impossible to enumerate here the legal qualifications required by all the different European universities; it will therefore be sufficient to mention these recognised in the British dominions.

In the university of Oxford, for the degree of Bachelor of Medicine, it is necessary that the candidate should have completed twenty-eight terms from the day of matriculation; that he should have gone through the two examinations required for the degree of bachelor of arts; that he should have spent at least three years in the study of his profession; and that he should be examined by the Regius Professor of medicine and two other examiners of the degree of M.D. in the theory and practice of medicine, anatomy, physiology, and pathology; in materia medica, as well as chemistry and botany, so far as they illustrate the science of medicine; and in two at least of the following ancient medical writers, namely, Hippocrates, Celsus, Aretæus, and Galen.

For the degree of Doctor of Medicine, the candidate is required to have completed forty terms from the day of matriculation; and to recite publicly in the schools a dissertation upon some subject, to be approved by the Regius Professor, to whom a copy of it is afterwards to be presented.

At Cambridge a student, before he can proceed to the degree of Bachelor of Medicine, must have entered on his sixth year, have resided nine terms, and have passed the previous examination: the necessary certificates, &c. are much the same as those required at Oxford. A Doctor of Medicine must be of five years' standing from the degree of M.B.

Since the university of London has been chartered, in 1837, the degrees of Bachelor and Doctor of Medicine, among others, have been conferred there. The following are the regulations for these degrees.

For the degree of Bachelor of Medicine.—Candidates to have been engaged for four years in professional study at one or more of the recognised institutions, one year at least to be spent at a recognised institution or school in the United Kingdom. They have also to pass two examinations, at the first of which they must produce certificates of having completed their nineteenth year; of having taken a degree in arts in this university, or in a recognised university, or of having passed the matriculation examination, of having been student for two years at one or more recognised medical institutions, subsequently to having taken a degree in arts; of having attended a course of lectures on descriptive and surgical anatomy, general anatomy and physiology, comparative anatomy, pathological anatomy, chemistry, botany, materia medica and pharmacy, general pathology, general therapeutics, forensic medicine, hygiene, midwifery, surgery, medicine; of having dissected during nine months; of having attended a course of practical chemistry; and of having attended practical pharmacy. Candidates to be examined in anatomy, physiology, chemistry, structural and physiological botany, materia medica, and pharmacy.

To the second examination no candidate can be admitted until two years after passing the first. He must produce certificates of having passed his first examination; of having subsequently attended a course of lectures on each of two out of the four subjects mentioned above; of having subsequently to his first examination dissected for six months; of having conducted at least six labours; of having attended the surgical practice of a recognised hospital or hospitals during twelve months, and lectures on clinical surgery; of having attended the medical practice of a recognised hospital or hospitals during other twelve months, and lectures on clinical medicine; of having subsequently attended to practical medicine in a recognised hospital, infirmary, or dispensary, during six months. The candidate must also produce a certificate of moral character from a teacher in the last school at which he has studied. Candidates to be examined in physiology (including comparative anatomy), general pathology, general therapeutics, hygiene, surgery, medicine, midwifery, and forensic medicine.

For the degree of M.D.—Candidates to produce certificates: 1, of having taken the degree of Bachelor of Medicine in this university, or a degree in medicine or surgery at a university recognised by this university; 2, of having subsequently attended (A) to clinical or practical medicine during two years in a recognised hospital or medical institution; (B) or to clinical or practical medicine during one year in a recognised hospital or medical institution, and of having been engaged during three years in the practice of his profession; (C) or if he have taken the degree of B.M. in this university, of having been engaged during five years in the practice of his profession; 3, of moral character, signed by two persons of respectability.

Candidates who have not taken a degree in arts, or passed the matriculation examination in this university, will be required to translate a portion of Celsus 'De Re Medicâ.'

REGULATIONS RELATING TO PRACTITIONERS IN MEDICINE OR SURGERY DESIROUS OF OBTAINING DEGREES IN MEDICINE.

Degree of Bachelor of Medicine.—Candidates shall be admitted to the two examinations for the degree of Bachelor of Medicine on producing certificates: 1, of having been admitted, prior to the year 1840, members of one of the legally constituted bodies in the United Kingdom for licensing practitioners in medicine or surgery; 2, of having received a part of their education at a recognised institution or school, as required by the charter of the university; 3, of moral character, signed by two persons of respectability.

Degree of Doctor of Medicine.—Candidates who have been engaged during five years in the practice of their profession, shall be admitted to the examination for this degree on producing certificates: 1, of having been engaged during five years in the practice of their profession; 2, of having taken the degree of Bachelor of Medicine in this university.

In Scotland the degree of doctor of medicine is conferred by the universities in Edinburgh, Glasgow, Aberdeen, and St. Andrews, from which last named university a diploma can still be obtained without residence; the regulations at the others contain nothing particularly worthy of notice.

In Ireland, the King and Queen's College of Physicians exercise much the same jurisdiction as the English college. The degrees of Bachelor and Doctor of Medicine conferred by Trinity College, Dublin, rank with the same degrees respectively from Oxford and Cambridge, and are never given without previous study in arts, which occupies four years. For the degree of M.D. five years must have elapsed since the degree of M.B was conferred; the candidate is then to undergo a second examination, and write and publish a Latin thesis on some medical subject.

By the English law the physician is exempted from serving on juries, from serving various offices, and from bearing arms. He is (according to Willcock, p. 105) responsible for want of skill or attention, and is liable to make compensation in pecuniary damages (as far as such can be deemed a compensation) to any of his patients who may have suffered injury by any gross want of professional knowledge on his part.

In 1858, a new medical act obtained the assent of the legislature, entitled, "an act to regulate the qualifications of practitioners in medicine and surgery." The object of this act was to consolidate the various medical corporations of the United Kingdom, to secure reciprocity of practice throughout the British dominions, and by legal registration independent of the universities and colleges, to secure to the public the means of distinguishing between qualified and non-qualified practitioners. One of the distinguishing features of this act is the constituting a medical council, entitled, "the General Council of Medical Education and Registration of the United Kingdom." This council consists of one person chosen from time to time by each of the following bodies:—

The Royal College of Physicians.
The Royal College of Surgeons of England.
The Apothecaries Society of London.
The University of Oxford.
The University of Cambridge.
The University of Durham.
The University of London.
The College of Physicians of Edinburgh.
The College of Surgeons of Edinburgh.
The Faculty of Physicians and Surgeons of Glasgow.

One person chosen from time to time by the University of Edinburgh and the two Universities of Aberdeen collectively.[*]

One person by the University of Glasgow and the University of St. Andrews collectively.

The King and Queen's College of Physicians, Ireland.
The Royal College of Surgeons of Ireland.
The Apothecaries Hall of Ireland.
The University of Dublin.
The Queen's University in Ireland.

Six persons nominated by her Majesty by the advice of her privy council, four of whom are appointed for England, one for Scotland, and one for Ireland, and of a president to be elected by the General Council. The first president chosen under this act was Sir Benjamin Brodie, Bart.

The General Council appoints a registrar, who acts as secretary and treasurer.

Branch councils are also appointed for Scotland and Ireland, who have each a registrar, and other officers and clerks.

The act then provides for the registration of every person holding one or more qualifications from the following bodies. The Colleges of Physicians of London, Edinburgh, and Ireland. The Colleges of Surgeons of England, Edinburgh, Glasgow, and Ireland, the Apothecaries Society of London, and the Apothecaries Hall of Dublin, graduates in medicine of any university in the United Kingdom, and graduates of any foreign or colonial university or college practising as a physician previous to the first day of October, 1858. The fee charged for registration under this act is two pounds. The register containing the names and qualifications of all registered practitioners is published yearly.

The Council is given power to require that every university, corporation, or college, whose graduates, members or licenciates are entitled to register, shall cause them to go through such a course of education and examination as shall secure to persons obtaining such qualification the requisite knowledge and skill for the efficient practice of their profession.

Every person registered under this act is entitled according to his qualification or qualifications, to practise medicine or surgery, or medicine and surgery as the case may be, in any part of her Majesty's dominions, and to demand and recover in any court of law with full cost of suit, reasonable charges for professional aid, advice, and visits, and the cost of any medicines or other medical or surgical appliances rendered and supplied by him to his patient. A proviso is made, that it shall be lawful for any college of physicians to pass a bye law to the effect that no one of their fellows or members shall be entitled to sue in manner aforesaid in any court of law, and thereupon such bye law may be pleaded in bar to any action for the purposes aforesaid commenced by any fellow or member of such college.

A clause in this act defines the terms "legally qualified" and "duly qualified" medical practitioner, as meaning a person registered under this act.

Another important provision of this act is in reference to the publication of a common Pharmacopœia for the three kingdoms. Hitherto the Colleges of Physicians of London, Dublin and Edinburgh, have published from time to time their own Pharmacopœias, but the act provides that the General Council shall cause to be published under their direction a book, containing a list of medicines and compounds, and the manner of preparing them, together with the true weight and measures by which they are to be prepared and mixed, and containing such other matter and things relating thereto, as the General Council shall think fit, to be called the 'British Pharmacopœia,' and the General Council shall cause to be altered, amended and republished, such Pharmacopœia as often as they shall deem it necessary.

The passing of this act has caused a very considerable movement in the medical profession. The large body of men who practise in England as general practitioners are members of the College of Surgeons, and practise as and call themselves surgeons. They practise however not only surgery but medicine, and they claim as practitioners of medicine the style and title of physicians. Up to the time of the passing of the medical act the College of Physicians of London had repudiated the granting their diploma to those who sent out their medicines or practised surgery. But on the passing of this act, those who were registered as physicians by the diplomas of the Colleges of Physicians of Edinburgh or Dublin, were entitled to practise in all parts of the United Kingdom. This, accompanied with the lowering of the fee for admission by the College of Physicians of Edinburgh, led a large number of general practitioners to seek admission to that College. Shortly after the passing of the act, the College of Physicians in London instituted a year of grace, in which they admitted to the membership of the College also at a reduced fee, the graduates of universities and others practising medicine, who did not send out their medicines. This has led greatly to the increase of the number of members of the medical profession, who practise under the style and title of physician.

---

[*] The two universities of Aberdeen have since been consolidated.

Some idea of the amount of fees paid to physicians in the middle ages may be gained by what we are told of Petrus de Abano, one of the most eminent physicians of the 13th century. For visiting a patient out of his own city he charged one hundred and fifty francs (or about six pounds) per day; and that when sent for by Pope Honorius IV., he demanded four hundred ducats per day, or about seventy pounds. (Bayle's 'Dict.,' art 'Apone.') It should, however, be noticed that these charges were considered very enormous.

PHYSICIANS, ROYAL COLLEGE OF, the principal chartered medical body in England, was founded through the instrumentality of Linacre, who obtained, by his interest with Cardinal Wolsey, letters patent from Henry VIII., dated in the year 1518. This charter granted to John Chambre, Thomas Linacre, Ferdinand de Victoria, Nicholas Halsewell, John Francis, and Robert Yaxley, that they and all men of the same faculty of and in the city of London, should be in fact and name one body and perpetual community or college; and that the same community or college might yearly and for ever elect and make some prudent man of that community expert in the faculty of medicine, president of the same college or community, to supervise, observe, and govern for that year the said college or community, and all men of the same faculty, and their affairs, and also that the president and college of the same community might elect four every year, who should have the supervision and scrutiny, &c., of all physicians within the precinct of London. The statute 14 Henry VIII. confirmed this charter, and further ordained that the six persons above named, choosing to themselves two more of the said commonalty, should from henceforth be called and cleaped elects; and that the same elects should yearly choose one of them to be president of the said commonalty; and then provided for the election of others to supply the rooms and places of such elects as should in future be void by death or otherwise, which was to be made by the survivors of the same elects. The statute 32 Henry VIII. provides that from thenceforth the President, Commons, and Fellows might yearly, at such time as they should think fit, elect and choose four persons of the said Commons and Fellows, of the best learned, wisest, and most discreet, such as they should think convenient, and have experience in the faculty of physic, to search and examine apothecaries' wares, &c. This last appointment is independent of the constitution of the body, the persons so appointed being officers for a special purpose; and it has been usual to select for this office the same four persons in whom the government of the physicians is reposed by the charter and statute of the 14th of that king.

The constituted officers then of this corporation are the eight elects, of whom one is to be president, and four governors, who have generally borne the name of censors. There is nothing to be gathered from the charter or statutes in any way tending to exclude any of the elects, except the president, from the office of censor; and as no duties are assigned to the elects, except those of filling up their own number, electing one of themselves to be president, and granting testimonials to country practitioners, they may be rather regarded as candidates for the office of president than as active officers of the corporation. The college is bound to choose four censors, for the purpose of discharging the duties confided in it, which are to be executed by these officers. It is also incumbent on the elects to preserve their number, so that there may at no time be less than five, including the president, as they would not, after a further reduction, be capable either of electing a president or choosing others to fill the vacancies in their own body. (Willcock 'On the Laws of the Medical Profession,' p. 32.) It is evident that the charter so far incorporated all persons of the same faculty, of and near London, that every person on the 23rd of September, in the 10th year of the reign of Henry VIII., falling within that description, was entitled to be admitted into the association. Such of them as had availed themselves of this privilege, and others subsequently admitted, are the persons described by statute 32 Henry VIII., as "Commons and Fellows" (quoted in Willcock, p. 13). But as to the persons who should afterwards enjoy that distinction, the original charter and all subsequent statutes are silent. James I. and Charles II. granted charters to this body. The first is silent as to the mode of continuing it; but the charter of Charles, after limiting the number of fellows to forty, directed that when a vacancy should occur in that number, the remainder should elect one of the most learned and able persons skilled and experienced in physic, then of the commonalty of members of the college. Each of these charters seems to have been granted with the view to the enactment of a bill to the same effect, as the kings respectively pledged themselves to give it the royal assent. No statute has been at any time passed in pursuance of this purpose; and it is very doubtful how far and in what manner the charters have been accepted by the college, though they have certainly been several times acted upon. (Willcock, p. 34.)

The licentiates of the college who may practise within the precincts of London and seven miles round it were (until 1836) of three orders, namely, fellows, candidates, and mere licentiates. The last of these classes, generally denominated licentiates, are those who have only a licence to practise physic within the precincts above described. The second class was abolished in 1836. The first class are those who have received that licence, but whose licence also shows that they are admitted to the order of fellows. This licence has often been called a *diploma*, but as it confers no degrees, the word is not properly applied, according to its more strict signification.

The order of licentiates was created by the following clause of the charter of Henry VIII.:—"We have granted also to the same president and college or community, and their successors, that no one within the said city or within seven miles around may practise in the said faculty until admitted to this by the said president and community, or their successors for the time being, by the letters of the same president and college, sealed with their common seal, under the penalty of one hundred shillings for every month for which, unadmitted, he may have practised in the same faculty, half to be applied for us and our heirs, and half for the same president and college." Now the common law having given every man a right to practise in any profession or business in which he is competent, the effect of 14 Henry VIII. must be taken to be this, namely, it has left to every man his common law right of practising in the profession of physic, as in any other profession, if competent, and has appointed the president and college to be judges of this competency. (Willcock, p. 38.) The mode of examination is wholly in the discretion of the college, which has confided the immediate direction of it to the censors. It has, however, also appointed that the doors of the censors' chamber shall be open to all fellows who may think proper to be present, and that they may take part in the examination, should they think fit; and that the fellows may have an opportunity of availing themselves of this right, it is appointed that all examinations shall take place at a court held at certain regular intervals. (Ibid., p. 41.)

The order of Candidates was abolished in 1836, as above stated, but there were reserved to students then in the universities of Oxford and Cambridge their *inchoate* rights.

The order of Fellows comprises those who are admitted into the fellowship, community, commonalty, or society of the college. The charter incorporated all physicians then legally practising in London, so that each of them who thought proper to accept it became *ipso facto* a member or fellow; but as all future practitioners, within the precincts of and seven miles round that city, were required to obtain the licence of the college, there soon arose two orders of the profession. The fellows attempted by various bye-laws to limit their own number, but seem to have considered the licentiates as members of the college, or the commons, and themselves as forming a select body for the purpose of government. To this state of the society, the statute 32 Henry VIII. seems to allude in speaking of the "commons and fellows." The charter of Charles II. expressly notices these orders as forming the body of the society, inasmuch as it directed that new fellows should be elected from among the commons of the society. Ibid., p. 44.)

Up to a very recent period the College confined its election of Fellows to graduates of the universities of Oxford and Cambridge. This was done under the direction of certain bye-laws, which it appeared the College had not by its charters the power to enforce. These bye-laws have been now modified, and graduates of all British and other universities, being licentiates of the College, are open to election for the fellowship.

There is a third class of members of the College, called extra-licentiates, or licentiates *extra urbem*. They are examined by the president and elects of the College, by virtue of an Act of Parliament passed previously to the granting of the present charter of the College. By this Act, power was given to the president and elects to examine persons desiring to practise physic throughout England and Wales. After the College of Physicians obtained their charter this Act fell into desuetude; but the president and elects having made known their power at the beginning of the present century, the list of extra-licentiates gradually increased, till in 1851 they nearly equalled in number the licentiates of the College. By the charter of the College, they were held to have no right to practice their profession within seven miles of London; and in case any of the extra-licentiates came to reside within that distance of London, they were cited to appear and be examined before the censors for their licence to practise in London. This was not a mere formal examination, as instances have been known in which the censors have rejected candidates who had been admitted to practise by the elects The revival of the class of extra-licentiates by the elects, and the jealousy of the censors of this body of physicians, was one of the causes which led to the passing of the Medical Act of 1858, by which the extra-licentiates obtained the same right to practise in London as the licentiates. It was even doubtful, under the old law, whether the licentiate *intra urbem* had the right to prescribe beyond seven miles of London.

It would be impossible here to give an account of all the literary controversies in which the College of Physicians have been continually engaged, partly in support of their own just and undoubted rights, and partly in defence of their arbitrary and unwise limitations with respect to the election of fellows. A list of the titles of more than fifty pamphlets, &c., written for or against the college between the years 1665 and 1810, is given in a work entitled "An Exposition of the State of the Medical Profession in the British Dominions; and of the Injurious Effects of the Monopoly, by Usurpation, of the Royal College of Physicians in London,' 8vo, Lond., 1826, pp. 373. The following regulations for admission to the licence have been published by authority of the college.

Regulations of the Royal College of Physicians of London—The College of Physicians, having for some years past found it necessary, from time to time, to make alterations in the terms on which it would admit candidates to examination, and license them to practise as physicians, has reason to believe that neither the character nor object of those alterations, nor even the extent of the powers with which it is invested, has been fully and properly understood.

The college, therefore, considers it right at this time to make public a statement of the means which it possesses, within itself, of conferring the rank and privileges of physician on all those who, having had the advantage of a liberal education, both general and professional, can prove their qualifications by producing proper testimonials and submitting to adequate examinations.

Regulations regarding Certificates and Testimonials.—Every candidate for a diploma in medicine, upon presenting himself for examination, shall produce satisfactory evidence—1. Of unimpeached moral character; 2. Of having completed the twenty-sixth year of his age; and, 3. Of having devoted himself for five years at least to the study of medicine.

The course of study thus ordered by the college comprises :—

Anatomy and physiology, the theory and practice of physics, forensic medicine, chemistry, materia medica and botany, and the principles of midwifery and surgery.

With regard to practical medicine, the college considers it essential that each candidate shall have diligently attended, for three entire years, the physicians' practice of some general hospital in Great Britain or Ireland, containing at least one hundred beds, and having a regular establishment of physicians as well as surgeons.

Candidates who have been educated abroad will be required to show that, in addition to the full course of study already specified, they have diligently attended the physicians' practice in some general hospital in this country for at least twelve months.

Candidates who have already been engaged in practice, and have attained the age of forty years, but have not passed through the complete course of study above described, may be admitted to examination upon presenting to the censors' board such testimonials of character, general and professional, as shall be satisfactory to the college.

The first examination is in anatomy and physiology, and is understood to comprise a knowledge of such propositions in any of the physical sciences as have reference to the structure and functions of the human body.

The second examination includes all that relates to the causes and symptoms of diseases, and whatever portions of the collateral sciences may appear to belong to these subjects.

The third examination relates to the treatment of diseases, including a scientific knowledge of all the means used for that purpose.

The three examinations are held at separate meetings of the censors' board. The *vivâ voce* part of each is carried on in Latin, except when the board deems it expedient to put questions in English, and permits answers to be returned in the same language.

The College is desirous that all those who receive its diploma should have had such a previous education as would imply a competent knowledge of Greek; but it does not consider this indispensable, if the other qualifications of the candidate prove satisfactory; it cannot, however, on any account dispense with a familiar knowledge of the Latin language, as constituting an essential part of a liberal education; at the commencement, therefore, of each oral examination, the candidate is called on to translate *vivâ voce* into Latin a passage from Hippocrates, Galen, or Aretæus; or, if he declines this, he is, at any rate, expected to construe into English a portion of the works of Celsus, or Sydenham, or some other Latin medical author.

In connection with the oral examinations, the candidate is required, on three separate days, to give written answers in English to questions on the different subjects enumerated above, and to translate in writing passages from Greek or Latin books relating to medicine. Those who are approved at all these examinations will receive a diploma under the common seal of the College.

The College gives no particular rules as to the details of previous education, or the places where it is to be obtained. It will be obvious, however, from a reference to the character and extent of the study above described, the manner in which the examinations are conducted, and the mature age of the candidates, as affording full time for acquiring the necessary knowledge, that there will be ample security afforded to the public and the profession that none but those who have had a liberal and learned education can presume, with the slightest hope of success, to offer themselves for approval to the censors' board; and as the College trusts that, by a faithful discharge of its own duty, it can promise itself the satisfaction of thus continuing to admit into the order of English physicians a body of men who shall do it honour by their qualifications, both general and professional, it is prepared to regard in the same light, and address by the same appellation, all who have obtained its diploma, whether they have graduated elsewhere or not.

In drawing up and promulgating the above regulations, the College has endeavoured fairly to look at that which is substantial, rather than that which is merely nominal, in all that concerns the qualifications of its members. It has resolved to estimate all testimonials, whether they are presented under the name of certificates, diplomas, or degrees strictly with reference to their value, and to measure them by this standard alone, as parts of the previous qualification of candidates, which they are to verify in their examinations.

The College feels confident that it has overstepped neither the spirit nor letter of the laws which have invested it with the power of governing and legislating for the whole faculty of medicine within its jurisdiction, by thus earnestly endeavouring to maintain its character and reputation, and vindicate its claim to be the source of professional honour.

Dec. 22, 1838. FRANCIS HAWKINS,
Registrar.

The Medical Act of 1858 [PHYSICIAN] has very considerably modified the position and character of the College of Physicians of London. By giving the right to practise, according to their qualifications, to all practitioners registered under that Act, the exclusive privileges of the fellows and licentiates of the London College were abolished. The College of Physicians of Edinburgh at once opened its doors to all those who, by previous education and examination, were entitled to practise as physicians; and in order to prevent its own extra-licentiates, and those graduates in medicine practising in London and as physicians in the provinces, from obtaining their right to register from Edinburgh, the London College was compelled for some time to admit to its licence, at a fee of ten pounds, all those who were desirous of joining the College. At the same time, and for the same period, the College declared a year of grace for the admission of fellows, and a large number of licentiates were selected for this honour.

The future of the College is still, however, involved in obscurity. Whilst a large number of the fellows are still desirous of maintaining the College as an institution for uniting those only who practise strictly as consulting physicians, there are a number of the younger fellows who are anxious to place the College at the head of the whole profession, by instituting examinations which shall entitle the class of general practitioners to its diploma. Overtures have been made to the College of Surgeons to unite with the Physicians for this purpose, but they have hitherto refused to countenance such a plan. By the new Medical Act, the College of Physicians of London is entitled to apply for a new charter in the following clause: —"It shall be lawful for her Majesty to grant to the corporation of the Royal College of Physicians of London a new charter, and thereby to give to such corporation the name of 'The Royal College of Physicians of England,' and to make such alterations in the constitution of the same corporation as to Her Majesty may seem expedient; and it shall be lawful for the said corporation to accept such charter under their common seal, and such acceptance shall operate as a surrender of all charters heretofore granted to the said corporation, except the charter granted by King Henry VIII.; and shall also operate as a surrender of such charter, and of any rights, powers, or privileges, conferred by or enjoyed under an Act of the session holden in the 14th and 15th years of King Henry VIII., chap. 5, confirming the same as far as such charter and Act respectively may be inconsistent with such new charter. Provided, nevertheless, that within twelve months after the granting of such charter to the College of Physicians of London, any fellow, member, or licentiate of the Royal College of Physicians of Edinburgh, or of the Queen's College of Physicians of Ireland, who may be in practice as a physician in any part of the United Kingdom called England, and who may be desirous of becoming a member of such College of Physicians of England, shall be at liberty to do so, and entitled to receive the diploma of the said College, and to be admitted to all the rights and privileges thereunto appertaining, on the payment of a registration fee of two pounds to the said College." Up to the present time (1860) the College of Physicians has not applied for a new charter.

Much curious information respecting the antiquities of the College of Physicians is to be found in 'The Gold-Headed Cane,' an amusing and interesting little volume by the late Dr. Macmichael. He tells us (p. 120), that its very first meetings, immediately after its establishment, 1518, were held in the house of Linacre, called the Stone House, No. 5, Knight Rider Street, which still belongs to the College. About the time of the accession of Charles I., the College removed to another spot, and took a house of the Dean and Chapter of St. Paul's, at the bottom of Amen Corner. During the civil wars their premises were condemned as part of the property of the Church, and sold by public auction, on which occasion Dr. Hamey became the purchaser, and two years afterwards, 1649, gave them in perpetuity to his colleagues. The great fire of London, 1666, consumed the College and the whole of the library with the exception of 112 folio volumes. For the next few years the meetings of the fellows were generally held at the house of the president, while a new college was being built on a piece of ground that had been bought in Warwick Lane. This was completed in four years, and was opened, without any particular ceremony, on the 25th of February, 1764, under the presidency of Sir George Ent. Here the fellows continued to hold their meetings for about sixty years, when (as Dr. Macmichael says) "the change of fashion having overcome the *genius loci*," the present new college, at the north-east corner of Trafalgar Square, was opened on the 25th of June, 1825, and an elegant Latin oration was delivered by the president, Sir Henry Halford.

PHYSICS. The word *phy'sike* (φυσικὴ), or science of nature, might include in one general term all that is called mixed mathematics, natural philosophy, chemistry, and natural history. The title of physician, or student of nature, has become in our language synonymous with one who investigates the origin of diseases and the means of cure; but in the continental languages it still retains the more general signification. Also physic (the study of nature) has come to mean the drugs given to cure disorders, or medicines; and it would be difficult to name two more complete departures from etymology.

The plural physics is always used to mean the study of nature by means of the severer modes of investigation. Some apply it to the application of mathematics to material phenomena, and to this alone; others, distinguishing the preceding as mathematical physics, include under the general term the sciences of experiment. There is no usage which in any degree approaches a universal reception; we prefer the second-mentioned signification. In this country, the phrase *Natural Philosophy* usually includes all that is understood by the term *Physics*.

PHYSIOGNOMY (φυσιογνωμονια) is the art of determining the mental character of an individual by the examination of his countenance. The popular ideas of the indications afforded by different kinds of features, by the adoption of which almost every one is at times a practitioner of physiognomy, are nearly as definite as the few principles which those who have made it an object of peculiar study have established. The circumstance on which the chief and surest indications afforded by the countenance depend, is, that when certain feelings and habits are much indulged in, the positions of the features which are associated with them are apt to become permanent, either by the formation of wrinkles or other marks in the skin, or by the enlargement and disproportionate strength of the muscles chiefly exerted. Thus a person in the frequent habit of sneering contemptuously acquires at last a slight curve in his upper lip by the disproportionate size and power of its elevator muscle; he who is often meditating has the wrinkles of the slight frown and the contraction of the brows which are commonly associated with deep thought, permanently fixed; he who has his attention constantly alive to the objects around him acquires an expression of vivacity in the openness of his eye and the quickness of the motions of all the muscles of his face; while he, on the other hand, whose thoughts are rarely roused to active efforts, acquires a smoothness of feature and a sluggishness of action in the several parts of the face, which indicate that its muscles have been exercised as rarely and with as little energy as his thoughts.

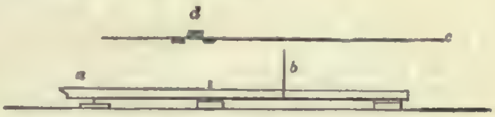
The peculiarities of feature thus acquired are often transmitted from the parent to the child; and in the latter, their indications will be correct or false according as there has or has not been a coincident transmission of the parent's disposition. Or a child may acquire a peculiar expression of countenance by imitating those among whom it is placed, and in this case also it will only be by accidental coincidence that the indications of the features are correct. From these and other sources of fallacy, the attempts to raise physiognomy into a science have not been so successful as to encourage a deeper study of it than every one unconsciously engages in during his intercourse with the world.

PIANO-FORTE, a keyed musical instrument, variously formed and under different denominations, such as *grand, semi-grand, square, cabinet, cottage,* &c. The first notion of the square piano-forte was taken from the clavichord by a German mechanic of the name of Viator, more than a hundred years ago; but, for want of friends or funds, he never became known as a maker. The invention, however, was followed up by other musical instrument makers of the same nation, who all ceased to produce clavichords and harpsichords, and directed their attention to the new instrument, the piano-forte. Thus we have Zumpe, Tabel, Schudi, Kirkman, Stodart, Schoene, Buntebart, Pohlman, Pether, Beck, Garcha, Ganer, and a host of others.

The grand piano-forte is supposed to be of earlier date than the square piano-forte, and is said to have been the invention of a German musician of the name of Schröder, or, as others say, of Christofali, a harpsichord-maker of Padua. The first maker at all known in this country was Backers; but we are not aware that success attended his exertions with the solid advantages which were enjoyed by his contemporary Zumpe, who realised an ample fortune and retired. The grand piano-forte retains the shape of the instrument from which it was taken, the harpsichord; and although that shape has been much condemned, it is the natural outline of the instrument; and we do not think that a better form for it will ever be devised.

The square piano-forte, we have said, was taken from the clavichord, but it retains only its shape, with the same disposition of the strings and keys; their actions have no similarity. We must here explain that the *action* of all such instruments is a technical name for all the mechanism which intervenes between the outer ends of the keys on which the fingers press, and the strings which emit the sounds; to describe the action, therefore, is to describe the essential parts of the instrument. The action of the clavichord was simply a piece of brass pin wire, which was placed vertically at a point where it could be struck or pressed against its proper strings. Each note had two strings. The right-hand string was free to vibrate; whilst that on the left-hand was muffled by a piece of cloth, the object of which was to damp or stop the string the instant the finger was taken off the key. The touch of the clavichord was peculiar, partaking both of the harpsichord and the organ; in other words, both *struck* and *pressed*, and the pressure could be so varied as to produce a kind of tremblant effect. The tones were feeble, soft, and melancholy, and better suited to the student, the composer, or the solitary, than any purposes of social amusement. A vertical section of this action is shown in *fig.* 1.

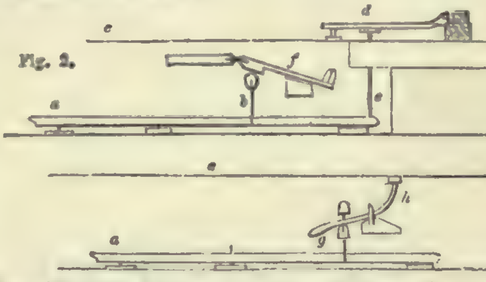
Fig. 1.



a, Key; *b*, Brass pin wire; *c*, String; *d*, Cloth woven between the strings as a damper.

The action of the square piano-forte, on its first introduction, consisted of a *key*, a *lifter*, a *hammer*, and a *damper*. The key was the same as that of the clavichord. The lifter was a brass wire, with a piece of hide leather as a head, which was covered with a piece of soft leather as a finish. This lifter, when in motion, struck the hammer against the string, and thus produced the tone of the instrument. The damper followed, and stopped the vibrations as quickly as the finger was removed from the key. (*Fig.* 2.) The tone of this piano-forte was thin and *wiry*, the hammer having only one slight covering of sheep-skin leather upon it.

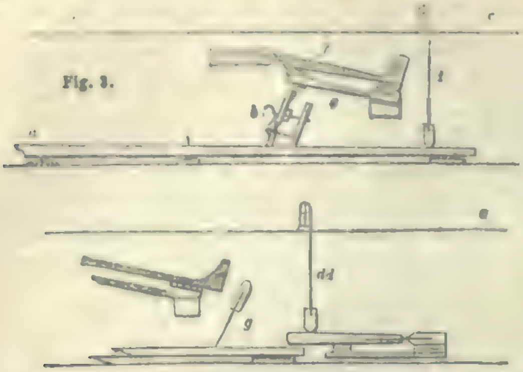
Fig. 2.



a, Key; *b*, Lifter; *c*, String; *d*, Damper; *e*, Damper stick or *mopstick*; *f*, Hammer; *g*, Lifter; *h*, Brass damper.

This rude idea of a piano-forte continued in use for many years. The first improvement upon it was introduced by Longman and Broderip, who brought out a patented invention having two additional parts in the action, namely, the *hopper* and the *under-hammer*, as they were called (*fig.* 3.) This patent was followed by another introduced by Clementi & Co., the burden of which simply was an improvement on the damper. It was called the *Irish patent*, from its having been the invention of an Irishman of the name of Southwell; but it had simplicity only to recommend it, was found inconvenient, and shortly afterwards was superseded by what is now called the *crank* damper. We cannot give the name of the inventor of this improvement; it became so instantaneously general, that the inventor was lost sight of in the crowd of makers who adopted his invention. It is still in use, and is acknowledged to be a good and sufficient plan. The damper used by Messrs. Broadwood previously to the introduction of the crank damper was made in brass (*fig.* 2), but by whom invented we do not know. We now come to the last addition which has been made to the action of the square piano-forte, the *check*. This member was borrowed from the grand piano-forte, and is so acknowledged by the name given to those square piano-fortes which have it; for they are always called, par excellence, *grand-square piano-fortes*. The check certainly is a most important part of a piano-forte, and the best of actions is nothing without it. The check is placed behind the hammer, nearly at the end of the key; where, after the blow has been given, it catches the tail of the hammer, and holds it till another is required (*fig* 3). For further information as to the square piano-forte, we refer to the diagrams. The square piano-forte has neither the touch, the tone, nor the appearance of either the grand or the upright.

Fig. 3.

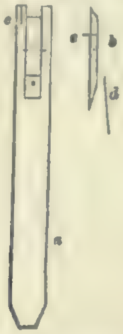


a, Key; *b*, Hopper, by which the escape of the hammer is effected; *c*, String; *d*, Irish damper; *dd*, Crank damper; *e*, Under hammer; *f*, Hammer; *g*, Check.

The grand piano-forte, as above observed, was the invention of Schröder or Christofali, manufactured by Backers, and retains the shape of the instrument from which it was taken, the harpsichord. Here again we have two instruments alike in *form*, but unlike in almost every other circumstance; for their action, their tones, and the style in which they are played upon, are all entirely different. The action of the harpsichord was simply a key and what was called a *jack*, a piece of pear-tree with a small moveable tongue of holly, through which a cutting of crow-quill was passed to touch the string when the jack was in action; the tone produced by this contrivance was a kind of *scratch* with a sound at the end of it.

Harpsichord Jack.

Fig. 4.



a, Jack; *b*, Tongue; *c*, Quill; *d*, Bristle-spring; *e*, Cloth damper.

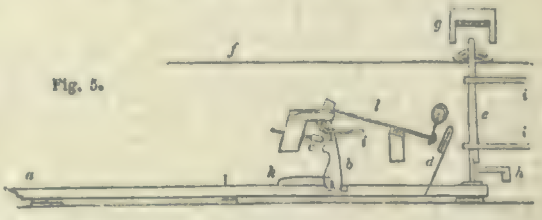
The action of a grand piano-forte consisted of a *key*, a *lever*, a *hammer*, a *button*, a *check*, and a *damper*, with rails and sockets to connect them. By this combination of parts, every musical intention known or desired at that time was perfectly attainable, and with admirable effects by Mozart, Haydn, Cramer, and others. But we have now new and more severe judges to encounter: former actions are no longer sufficient; new effects are to be given, and new powers are called for. Fortunately, these things have been accomplished; for new actions have risen up in abundance, and we have only to choose between them.

No musical instrument is so universally admired as the piano-forte. Its compass, whether six octaves, six and a half, or seven, is sufficient for all purposes of musical composition, and may really be considered a miniature orchestra. The strings of the early piano-fortes were partly of steel and partly of brass—the treble notes of steel, and the lower notes of brass—a few of which, in the bass, were over-lapped or covered, rather open, with plated copper-wire to give them more gravity according to the length attainable in the instrument. But modern piano-fortes have steel wire throughout, with about an octave in the bass closely lapped with unwashed copper wire. The strings which are now used in piano-fortes are considerably larger than those formerly used, to give durability and firmness. The once-famed German wire is now no more in esteem with English manufacturers, from the bad quality of the metal and the very imperfect manner in which it was drawn; when perfectly round, which it ought always to be, it was generally too soft; and when sufficiently hard, it was scarcely ever well manufactured, from which circumstance it was constantly false in vibration. Steel-wire for piano-fortes, of very excellent quality, is now made at Birmingham. Stops and pedals are more or less adopted in different countries. Stops can scarcely be said to be used at the present day; they properly belong to the middle age of piano-forte making, and were placed in the instrument on the left hand of the performer. The damper-stop and the buff stop were the most common; the damper-stop raised the dampers from the strings, which gave continuation to the tones; and the buff-stop raised a piece of soft buff leather up to the strings, and gave the instrument somewhat the tone of the harp. Pedals are much esteemed by some performers and little by others; in foreign piano-fortes we find many pedals, but in the English we have scarcely ever more than two—one for piano effects, and the other for forte. This pedal, the forte, is an effective pedal, and not at all injurious to the mechanism of the instrument; we cannot say as much of the piano pedal, for by passing the action to one string, it is not only straining to the centres of the hammers, but is also very apt to disturb the tuning of the unisons, by which an instrument is often unfairly tested as regards its standing, and a more frequent application to the tuner is required. In lieu of this pedal, some makers have introduced a soft substance, wool or leather, between the hammers and the strings, by which something like the buff stop is accomplished, but with more delicacy and vibration in its effects. The foreign name for this pedal is *jeu céleste*; and to us it is more agreeable, and is certainly less injurious to the action of the instrument, than the more frequent piano pedal.

We will here give a few diagrams of grand actions.

The Common Grand Piano-forte Action.

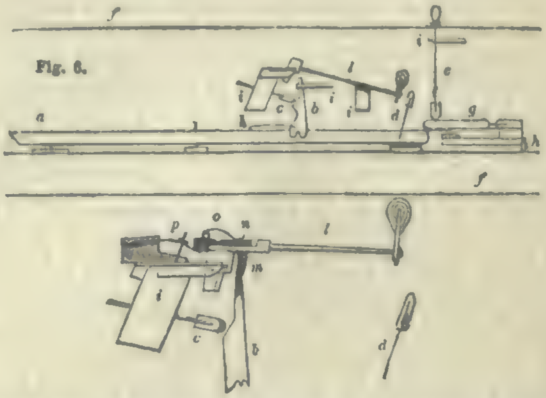
Fig. 5.



a, Key; *b*, Lever; *c*, Button; *d*, Check; *e*, Damper; *f*, String; *g*, Ruler; *h*, Damper pedal lifter; *i i i*, Rails and sockets; *k*, Spring; *l*, hammer.

Broadwood's earlier and later Grand Actions.

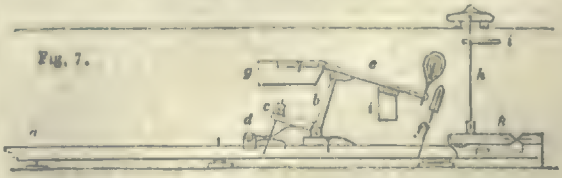
Fig. 6.



The shaded parts are the new additions, the intention of which is to keep the hammer at a certain distance from the string when the finger is on the key. *a*, Key; *b*, Lever; *c*, Button; *d*, Check; *e*, Damper; *f*, String; *g*, Crank for damper; *h*, Damper pedal lifter; *i i i i*, Rails and sockets; *k*, Spring; *l*, Hammer; *m n*, Block passed through the hammer butt; *o*, Spring fixed at the back of *n*, and pressing upon the front of it; by which arrangement, when the lever passes the notch, it is caught by *m*, and the hammer is sustained at the given height; *p*, Another spring, which regulates the action of *o*, and determines the height it shall rise.

Collard's Grand Action.

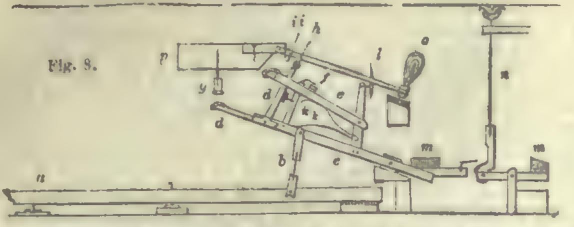
Fig. 7.



a, Key; *b*, Hopper; *c*, Button; *d*, Hopper spring; *e*, Hammer; *f*, Check; *g*, Hammer rail; *h*, Damper; *i i*, Rail and socket; *k*, Crank for damper; *l*, Damper pedal lifter.

Erard's Grand Action.

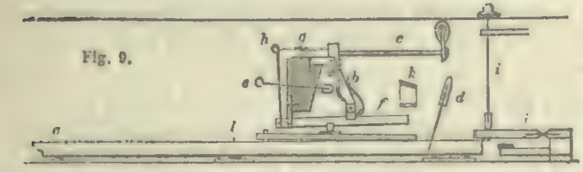
Fig. 8.



a, Key; *b*, Lifter centred in the key and the hopper lever; *c*, Hopper lever; *dd*, Hopper; *e*, Hammer sustaining lever; *f*, Stop for *e*; *g*, Hopper button; *h*, Butt for the hopper to hit against; *i i*, Two small wire stops acting upon *e*; *k k*, Hopper and sustaining spring; *l*, Check; *m m*, Balance weights of lead; *n*, Damper; *o*, Hammer; *p*, Hammer rail.

Wornum's Grand Action, based on the Piccolo Action.

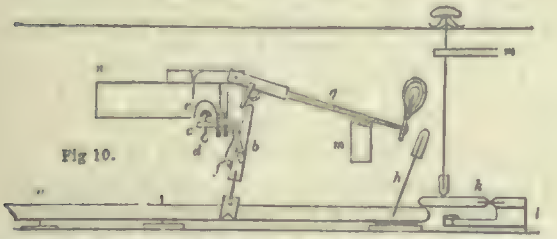
Fig. 9.



a, Key; *b*, Hopper and spring; *c*, Hammer; *d*, Check; *e*, Button to set off the hopper; *f*, Hopper lever; *g*, Tie attached to the butt of the hammer. *h*, Sustaining spring linked to the end of the tie, and fixed in the front end of the hopper lever, the rising of which puts the sustaining spring in action. This spring gives the *piano* blow and assists in the *forte* and repetition; *i i*, Damper and fixings; *k*, Hammer ruler and back touch; *l*, Wood spring to set up the hoppers.

Zeitter's Grand Action.

Fig 10.



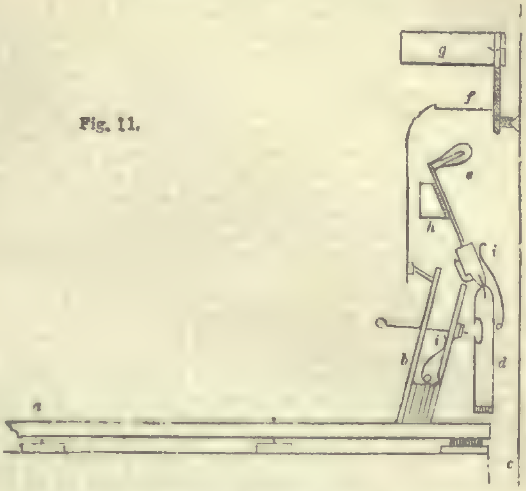
a, Key; *b*, Hopper, which works in the key with what is called a *bird's mouth*; *c*, Escapement part of the hopper and the setting off is effected by the button working in the arched part above it, *d*, *e*; *d*, Button and wire; *e*, Arch in which the button acts; *f*, Hopper spring; *g*, Hammer; *h*, Check; *i*, Damper; *k*, Damper crank; *l*, Damper pedal action; *m m*, Rail and socket; *n*, Hammer rail.

Some of the above-named makers have patented still more recent actions for grand piano-fortes, as also have other makers not here named.

The *upright* piano-forte was, doubtless, taken from the upright harpsichord; it was the invention of an Englishman of the name of Hancock, a musical instrument maker resident in some part of Westminster. He was a man of much ingenuity, and produced several varieties in keyed instruments; amongst which we find the *organised piano-forte*, the *portable grand* piano-forte, and an instrument, also a piano-forte, in the shape of a *spinnet*. The portable grand, in its day, was a successful and desirable instrument, but has long since been superseded by instruments of the kind called *kit* grands, *boudoir* grands, *pocket* grands, and *semi* grands. The next novelty was the invention of John Isaac Hawkins, who constructed an upright instrument with a detached sound-board in an iron frame; and the whole was so arranged as to be able to meet the atmosphere with compensating powers. In the bass it had spiral or helical strings, by which length was gained; and, in the treble, three octaves of equal tension were accomplished by a uniform size of wire. It was patented, but did not take with the public sufficiently to come into notice. Following Hawkins we had William Southwell, who patented an improvement in upright piano-fortes, and gave it the name of the *cabinet piano-forte*. The name still remains amongst us, but the invention has long since been superseded and laid aside. The *unique* piano-forte was introduced about fifty years ago by Messrs. Wilkinson and Wornum, and was the invention and patent of the latter. This instrument met the taste of the day for instruments of *little altitude*; it did not stand higher than *three feet three inches*, and the strings were all placed *diagonally* towards the floor. The action was simple and effective, but it is not now under manufacture.

Wornum's Patent Unique Action.

Fig. 11.

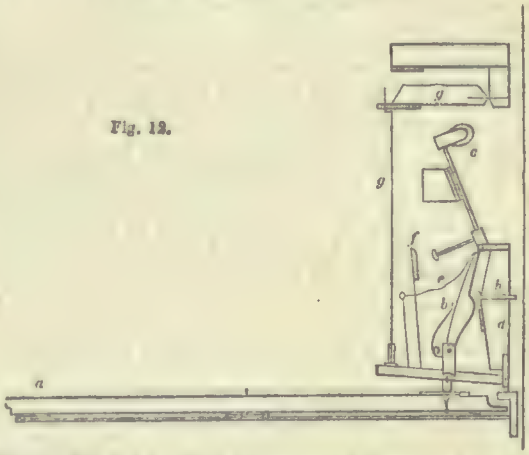


a, Key; *b*, Hopper; *c*, String; *d*, Hammer rail; *e*, Hammer; *f*, Damper and wire; *g*, Damper rail: *h*, Ruler; *i i*, Springs.

Numerous inventions and improvements appeared from time to time. One of these was Mr. Wornum's *double* or *piccolo action*, applicable to both upright and horizontal instruments; and another was the *cottage* form, now so much in use.

Wornum's Double or Piccolo Action.

Fig. 12.



a, Key; *b*, Hopper and spring; *c*, Hammer; *d*, Hammer rail; *e*, Tie and wire; *f*, Check; *g g*, Damper and wire; *h*, Setting off screw.

There are many things relating to the piano-forte which we have not touched upon. There are also some foreign actions to which we have not given much attention, especially those called *down-striking* actions. Other inventions, too,—such as Mr. Litherland's patent helical springs to preserve the tuning, Mr. Riley's transposing instrument, Mr. Mott's sostinente, Mr. Kirkman's octave string, and Mr. John Trotter's alternated key-board,—have all given place to other things, and are no longer known to the present generation of musical people. Mr. Litherland's plan was a well-tempered *helical spring*, which was to be attached to the loop of the string; thus, as the string contracted the spring gave way, or as it expanded the spring collapsed, by which the pitch of the string was retained and the tuning consequently preserved. It was never adopted to any great extent, but had its admirers: a want of firmness in the tone was perhaps its greatest defect. Mr. Riley's plan for *transposition* was simply a double set of keys, one sliding under the other, by which music might be played from the same scale a note or notes *higher* or *lower*. It was purchased by Messrs. Broadwood, and is now laid aside. It never was calculated to be of service to the practice of music; neither did it introduce any new or valuable idea to the mechanic. Mr. Mott's *sostinente* was an application of a cylinder and silk loops to an upright piano-forte. The loops were attached to the strings, and the cylinder, which was moved by the foot, as it were *bowed* them, and the tones came forth somewhat like the tones of the seraphine. Under Mr. Mott's fingers, this instrument was capable of most pleasing effects; but without such aid, we never esteemed the invention. Mr. Kirkman's *octave string* was applied as the third string of a grand piano; this string was an octave higher in pitch than the other two, and was somewhat in effect like two diapasons and a principal in an organ, but not so marked in character. It pleased for a time, but is now no more thought of. In Mr. Trotter's *alternated key-board* the peculiarity was that of alternating the keys: thus the octave came within seven white keys; the black keys, too, were passed *under* the *white*, and finished in front of them *below* with *broad heads;* by which arrangement a black key could be taken by either the *thumb* or the *finger*, at the option of the performer. This instrument was called by Mr. Trotter a *transposing piano-forte*; and he went so far as to promise a *new notation* for it, which notation he seemed to think would do away with the present altogether. That he did not live to perform his promise we much regret; for, certainly, double sharps and double flats, with all their accidentals, are anything but agreeable to those who cannot devote their whole lives to the study of music.

In relation to the *bracing* of piano-fortes, there is a difficulty in giving strength to that of the squares and grands. Some makers are for iron, and some for wood; but wood, it seems, is inconvenient, and iron is therefore mostly adopted. That strength is important, and very important, is quite clear, when we know that the strings of a grand piano-forte pull equal to a weight of *six tons*. Iron as a substance, doubtless, has the greater strength, but may not wood be so applied as to be strong enough? That wood is more sonorous than iron, there has never, we believe, been a question; and we will yet hope that, sooner or later, it will be allowed to be a better material.

The piano-forte manufacture is now conducted in this country on a very large scale, and comprises processes of the highest order in the working of wood. The recent cheapening of the instruments has resulted in part from the lessening of profits, by the establishment of a number of small manufactories in competition with the few older firms. But it remains nevertheless true, that a large capital, aided by highly-paid workmen's skill, are necessary for the production of the best instruments. Such firms as Broadwood's, Collard's, &c., keep timber in store for many years, and bestow extraordinary care upon it, that it may be perfectly seasoned before being used. Specimens of wood of more than usual beauty are eagerly bought by such firms at enormous prices: an example of this has been noticed in the article MAHOGANY. Some of the piano-fortes now made, having the most complex and elaborate actions, consist of very little less than four thousand separate and distinct pieces, each of which, according to its material and character, has to be carefully fashioned before being adjusted to its place. The material thus used comprises ivory, ebony, cedar, sycamore, lime-tree, pine, and oak, according to the kind of service required; besides the mahogany, rosewood, or walnut-wood of the exterior; and besides steel, iron, brass, lead, cloth, felt, leather, and vellum.

The great extension of piano-forte music in families, and the unceasing demand in the Australian and American colonies, have led to a notable extension of the piano-forte manufacture within the last few years.

PIASTRE. [MONEY.]

PIAZZA, a term adopted in its original form from the Italian, but with a great change of its meaning; for while in that language it signifies merely an open place, it is employed by us to denote a covered ambulatory, whether formed by columns or arches, in the lower part of a building, such cloistered walks being very common in the *piazze* or public squares of Italian cities, as that of St. Mark's at Venice, &c. Yet, although we have borrowed the term, it has been rather as a distinct name applied in a few particular cases, than as a general denomination; for Inigo Jones's arcade, on the north and part of the east side of Covent Garden, which is expressly called the "Piazza," is the only example, except on a very small scale, that we can refer to in London.

PIBROCH, in Scottish music, the march or battle-tune of the Highland clans.

PICAMAR. [TAR.]

PICHURINSTEARIC ACID. [LAURYL; LAURIC ACID.]

PICOLINE ($C_{12}H_7N$), is a volatile oily base, isomeric with aniline, and found in coal tar. It has very powerful basic properties, and is probably the same substance as the *odorine* described by Unverdorben.

PICRAMIC ACID. [PHENYLIC GROUP.]

PICRANISIC ACID. [PHENYLIC GROUP.]

PICRIC ACID. [PHENYLIC GROUP.]

PICROLICHENIN. A colourless crystalline bitter body, found in the *variolaria amara*. It fuses below the boiling point of water, and is insoluble in water, but very soluble in alcohol and ether. Its exact composition is not known, but it does not contain nitrogen.

PICROTOXIN ($C_{10}H_6O_4$). The active principle of *cocculus indicus*. It crystallises in white quadrilateral prisms, is neither acid nor alkaline, but has an intensely bitter taste. It is excessively poisonous; one-third of a grain introduced into the stomach of a cat produced tetanic convulsions and death in ten minutes.

PICRYL ($C_{42}H_{15}NO_4$) is yielded by the distillation of the product obtained by acting on oil of bitter almonds with sulphide of ammonium. By the action of nitric acid it is converted into *trinitropicryl* $C_{42}\left\{\begin{matrix}H_{12}\\ 3\,NO_4\end{matrix}\right\}NO_4$ which is a yellow crystalline powder.

PICTS, an ancient people of North Britain, whose origin and history are singularly obscure, and have furnished matter for endless speculation and controversy. The name does not occur in the enumeration of the British tribes given by Ptolemy in the beginning of the 2nd century; nor are the Picts noticed by his successors Dion Cassius and Herodian, the latter of whom wrote about A.D. 250, any more than they are by his predecessors Julius Cæsar and Tacitus. This has not prevented some writers from maintaining that the Picts were settled in Britain before Cæsar's invasion; that is, for instance, the opinion of Pinkerton; but it is certainly at least in the highest degree improbable that they should have been passed over by Ptolemy if they were here in his time. The earliest mention of them by any ancient writer occurs in an oration addressed by the rhetorician Eumenius to the emperor Constantius Chlorus, on his return from his victory over the usurper Allectus, in the year 296. Eumenius there speaks of the Britanni in the time of Julius Cæsar (according to the best reading of the passage) as "Solis . . . Pictis modo et Hibernis adsueti hostibus' —having been used only to the Picts and Irish as enemies.

After the time of Eumenius we have frequent mention of the Picts in the Roman writers. Ammianus Marcellinus, under the year 360, speaks of the invasion of the borders of the Roman province in Britain by those wild nations the Scots and Picts—"Scotorum Pictorumque, gentium ferarum." Again, in 364, he enumerates the "Picti, Saxonesque, et Scotti, et Attacotti," as harassing the Britanni with incessant attacks. We may just observe that the Scoti or Scotti mentioned in these two passages were in all probability not yet inhabitants of any part of Britain any more than were the Saxones. But the most important passage in Marcellinus relating to the Picts, although it refers to another probably still more important, which is unfortunately lost, occurs in his annals of the year 368, where he says that, in relating the actions of the emperor Constans (A.D. 337-350), he had already described as well as he could the situation of Britain, and that therefore it is necessary for him only to observe now, that at that time "Picti, in duas gentes divisi, Dicaledonas et Vecturiones, itidemque Attacotti bellicosa hominum natio, et Scotti per diversa vagantes, multa populabantur." It thus appears that about the middle of the 4th century the Picts were understood to be divided into two tribes, the Dicaledonæ, or Dicaledones, and the Vecturiones. These two names have however occasioned much perplexity. The Vecturiones, or Vecturones, indeed, are mentioned by Richard of Cirencester, whose work however is possibly nothing more than a modern forgery; but the name Dicaledones occurs nowhere but in this passage of Marcellinus. Skene ('The Highlanders of Scotland, &c.,' 1837) maintains that the Picts and Caledonians were the same. The Vecturiones are admitted to be Picts, and if for Dicaledones we should read, as has been proposed, Deucaledones, the meaning of which is "genuine Caledonians," as in Du Albinnach, a genuine Scotsman, the two tribes would appear to include the whole population.

It is very doubtful indeed in how far we are to understand the Roman writers as meaning at all the same people we now call the Picts by their term *Picti*. That term seems always to have been used by them in the sense simply of painted men, rather than as the name of any particular people. At least this notion, which we find Claudian indicating in his "nec falso nomine Pictos" ('De Text. Cons. Honorii'), and in other passages, seems always to have been suggested to them by the name, and to have therefore induced them to apply it loosely to all the wild inhabitants of the north of Britain who were in the habit of painting their bodies, or rather among whom they supposed that practice to exist; and they were probably the descendants of a primitive race, or the oldest of which we have any trace, the Albiones of Festus Avienus, and the Albinnach of the Welsh and native writers. Moreover, a derivation has been more recently traced in the Welsh *peith*, to fight or scream, whence *pic-t-a*, a fighting man.

That there was in early times a people settled in North Britain bearing a name of which the Latin *Picti* was intended as the representative, may be pronounced to be a fact only to be disputed by that sort of scepticism which is not less hostile to the investigation and establishment of historic truth than the weakest credulity. They are mentioned under the name of Picti not only by Eumenius, Marcellinus, Claudian, and other Roman writers, but by Gildas, Nennius, Bede, and Paul Warnfrid (Paulus Diaconus), all of whom lived while the Pictish kingdom still subsisted in the country now called Scotland; Bede even gives a history of the first settlement of the Picts in North Britain, which may be correct or not, or partly truth, partly fable, but which agrees in some remarkable points with the accounts both of the Irish and of the Norwegian or Icelandic annalists; the Saxon Chronicler and other contemporary writers of that nation speak of them under the names of *Peohtas, Pyhtas, Pihtum,* and *Pehiti;* the Welsh historical fragments call them *Phichtjaid;* the Icelandic writers, *Pets;* the ancient Irish annalists, *Cruithne* for the northern Picts, while the southern were called *Piccardach*, names which are sufficiently ascertained to indicate the same people: and popular tradition in Scotland still remembers them under the name of *Pechs* (pronounced with a deep and prolonged guttural intonation), which is probably as near their true name as any of the other forms.

The main dispute with regard to the Picts, as with regard to the Caledonians, with whom they have been sometimes identified, the Scots, the Cimbri of antiquity, and the Cymry or modern Welsh, the

Belgæ and the Irish Firbolgs, has been, whether they were a Celtic or a Teutonic people. Their Teutonic lineage is maintained by Usher, Stillingfleet, and Pinkerton; that they were Celts is the opinion of Camden, Bishop Lloyd, Father Innes, George Chalmers, Ritson, and others. The historic evidence that bears upon the point does not amount to much; all that can be said is, that the various old legendary accounts all make them to have come to Britain from Scythia or from Scandinavia. But the most curious and valuable fact that we possess in relation to this matter is, that their language appears to have nearly resembled the Welsh, and the Welsh Triads uniformly term them *gwyddyl Ffichti*, the Gaelic or Celtic Picts. One Pictish word only has been expressly mentioned by any old writer. *Peanvahel*, Bede tells us, was the Pictish name of the place at which the wall of Antoninus terminated on the Forth, and which Nennius says was called in Welsh *Pengaaul* (Pengual?), and in Scotch (*Scotice*) *Cenail*. It is still in fact known by the name of Kinneil. *Cen*, or *Cean*, is the Irish or Gaelic word for a head, and Cenail in that dialect would mean the head of the wall; and that is also the signification of the Welsh name, with which the Pictish is evidently identical. It is remarkable that in Angus, and the other counties on the north-east coast of Scotland where the Picts were longest established, the popular speech is still characterised by the peculiarity of the substitution of the element *f* for *w*, or *wh*, or *gw*. Thus, for *what* the people of that district all say *fat*, just as their Pictish ancestors for Pengual said Penfahel or Penfal. And generally it appears that the ancient names of places in those parts of Scotland formerly occupied by the Picts are Welsh, as was long ago pointed out by Camden, and afterwards more fully established by George Chalmers, in his 'Caledonia;' and has been substantiated by most subsequent investigations.

The greatest diversity of opinion has also prevailed as to the extent of the territory occupied by the Picts in the north of Britain. Pinkerton, who considers the Picts to be the same people with the Caledonians, holds them to have occupied not only the Orkney Islands and the Hebrides, but the whole of Scotland to the north of the Friths of Forth and Clyde, and to have extended their conquests on the east coast as far south as to the Humber. There is every reason indeed to believe that they were at one time in possession of a considerable territory to the south of the Forth. Bede expressly states that in his time the English held possession of the Pictish province in which stood Aebbercurnig, now Abercorn, in West Lothian, the seat of one of their bishops. Here too was Peanvahel, now Kinneil; and Edinburgh, farther to the east, on the same side of the Forth, is also described by old writers as having been at one time within the dominion of the Picts. But, at least during the greater part of the time that it subsisted, the Pictish kingdom appears to have been bounded by the Frith of Forth to the south, and to the west by the mountainous range still separating the Lowlands from the Highlands of Scotland. The kingdom of Strath-Clyde, or Cumbria, however, or Reged (that is, the kingdom, by way of pre-eminence), as it was usually designated by the Welsh, which comprised the south-west of Scotland, and perhaps also the county of Cumberland (if that did not form a separate state), must be regarded as having also been Pictish on the hypothesis which assumes the Picts to have been the same people with the Welsh, the latter being admitted on all hands to be of the same race with the people of Strath-Clyde.

The history of the Pictish kingdom established in the north-east of Scotland is, as may be supposed, exceedingly scanty and obscure. The Scottish and Irish chronicles however supply five different lists of the Pictish kings, no one of which evidently has been copied from another, although they all agree substantially, with the exception of such variations as tend to establish the independent authority of each. From these lists Pinkerton has framed a Pictish chronology, which he divides into two portions: the first, which he entitles Poetical, extending from the foundation of the monarchy by Cruthen, or Cruithne (whence the Irish name for the northern Picts), about A.D. 28, through a succession of thirty-six kings, ending with Talorc I., A.D. 414; the second, styled Historical, extending from the accession of the successor of Talorc, Drust the Great, through forty princes more, to the subversion of the monarchy in A.D. 843, in the reign of Brudi VII. Besides the succession of the kings, a few events of Pictish history are also recorded by the Irish and Icelandic, as well as by the less ancient Scottish chroniclers. These consist chiefly of the foundations of a few towns, and of battles fought with the Scots, or Irish colonists of the north-west of Scotland, with whom the Picts appear to have been almost constantly at war from the first establishment of these new settlers in the country about the beginning of the 6th century. Bede and Ailred state that the Southern Picts were converted to Christianity by St. Ninian about the year 412; but it may be doubted whether these were the Picts living between the Forth and the Grampians, as Bede affirms, or the people of Strath-Clyde, among whom it is known that Ninian was established as bishop of Whithern, now Whitehorn, in Wigtonshire. The conversion of the Northern Picts is attributed to St. Columba, about the year 565.

No passage of the obscure story of the Picts is involved in greater darkness than the sudden catastrophe which appears to have put an end to their dominion in their principal seat, the north-east of Scotland. The common account of the Scottish historians is, that the Pictish kingdom was conquered in the year 843 by the Dalriadic or Scottish king Kenneth II., who thus, for the first time, united the whole of North Britain into one monarchy. The oldest authorities for this account are the Chronicon Regum Pictorum, written apparently about the beginning of the 11th century (it comes down to the year 992), and first published by Father Innes, in 1729; and the Register of St. Andrew's, written about 1130. On the other hand it is extraordinary that no allusion should be made to any revolution as having taken place in Pictland about this time, either by Nennius, who wrote about 858, and who expressly states that the Picts then continued to hold a third part of Britain; by Asser, the biographer of king Alfred, who wrote before the end of the same century, and who speaks of the Danes ravaging the Picts in 875; by the Saxon Chronicler, by Ethelwerd, or by Ingulphus, who, in the 10th and 11th centuries, all continue to speak of the Picts as an existing people; by the Irish annalist, Tighernac, who wrote about 1088, and who continues a regular chronicle of the Pictish kings, among whom he reckons Kenneth himself, down to the death of his son Constantine II., in 875; by the Welsh annalists, who, in like manner, style Kenneth simply king of the Picts; or finally, by the singular genealogical poem, commonly called the Gaelic or Albanic Duan, belonging to the reign of Malcolm III. (1056-1093), which passes over the reign of Kenneth II. without any remark; though it states that the Cruithne had gone from Ireland, and seventy kings had possessed the Cruithne plains. It thus appears that neither the Irish, the Welsh, nor the Saxon annalists who lived nearest to the time, ever heard of this subjugation of the Picts by the Scots, which the later Scottish chroniclers would have us believe amounted to the entire destruction of the Pictish nation, and indeed to the utter extirpation of that people from the soil of Scotland. Nevertheless, the fact remains unquestionable and undisputed, that Kenneth II., or Kenneth Macalpin, as he is commonly called, having been originally king of the Scots, or Dalriads, became king of the Picts about the date assigned to his conquest of that people; and the probability therefore seems to be that this Dalriadic king had a claim by descent to the Pictish throne, and that the contest in which he proved victorious was in fact not a war between the Scots and Picts, but merely a dispute between him and a rival claimant for the crown of Pictland, which terminated in its acquisition by Kenneth, and consequently in the union of the two kingdoms under one sceptre. The two people also were of allied races, and might have easily amalgamated. Kenneth, we may here notice, appears to have followed up this success by a course of policy having for its aim the ultimate incorporation with his own dominions of the adjoining (perhaps Pictish) kingdom of Strath-Clyde; and that object was in fact accomplished, and the whole of what is now called Scotland brought (nominally at least) under one rule, in the year 973, in the reign of his great-great-grandson Kenneth III. Even down to a considerably later date than this, however, a great part of the north-east of Scotland appears to have been actually held by Norwegian princes, who did not acknowledge the sovereignty of the descendants of Kenneth Macalpin; and even some of the great Highland chiefs of the west long continued to maintain almost as substantial if not as openly avowed an independence.

Certain singular architectural remains found in some parts of Scotland are still popularly known there by the name of Picts' houses: and the Picts, or Pechs, live in the traditions of the country as a people of almost superhuman strength and dexterity. This would seem to indicate the possession by that race of a more advanced civilisation than belonged to the other races by whom they were surrounded. Many carvings on stone, of a very remarkable character, the prevailing emblems being a serpent with a zigzag line passing through it, and two or sometimes three circles united by double parallel lines, are scattered over the whole of the tract which once formed the dominion of the Picts; but these curious monuments have not yet received the investigation they deserve, and whether they are Pictish or Norwegian remains doubtful. Of these various works an interesting account is given in Daniel Wilson's 'Archæology and Prehistoric Annals of Scotland,' 1851.

PICTURE. [PAINTING.]

PICTURESQUE (in Italian *Pittoresco*, painter-like or picture-like, and therefore expressed in German by the word *Mahlerisch*, which is of exactly the same import) is that quality which peculiarly recommends objects for pictorial representation. Consequently, in order to ascertain wherein this quality consists, it is necessary to consider what it is that, independently of other things, contributes to the general effect of a picture, and recommends more particularly certain classes of objects as suitable for the pencil. A picture is a representation upon a plane surface of bodies in relief, delineated as they appear to the eye, by means of form and colour, and their accompanying light and shade, which degree of relief or illusion will generally be in proportion as the objects themselves are favourable to artistical execution on account of the apparent diversity and variety which they present to the eye, and with which they must accordingly be represented in painting, although in themselves, or taken separately, they may appear monotonous. Hence, provided any object presents that variety to the eye which the artist requires in order to display the *artifice* of his pencil, it matters not how unpicturesque it may be when otherwise viewed, or though it should possess in itself none of those qualities which are commonly insisted upon as essential to the picturesque.

"The ideas of *neat* and *smooth*," says Gilpin, who is generally referred to as an authority upon this subject, "instead of being picturesque, *disqualify* the object in which they reside from any pretensions to picturesque beauty." But how can we reconcile this theory with fact when we observe that many things which are remarkable for the very *smoothness* here objected to as a disqualification, are selected by the artist as being admirably suited for his pencil? Still it may be granted that whilst the painter often has to *suggest* the idea of neatness or smoothness in the objects he depicts, he is careful to avoid that degree of neatness and smoothness which the artisan aims to produce. Smoothness is one quality of satin and velvet; and the idea of smoothness, it may be presumed, and generally of uniformity of colour also, throughout the material, is excited in the beholder; but then, in order to produce such appearance in painting, the artist must employ a great number of tints and colours, some of them quite different from the local or positive colour of the object itself, in order faithfully to express all the various modifications which the actual colour of the object receives from light, when seen as it is intended to be represented in the picture.

Another opinion, which appears equally incorrect, is that the picturesque is something distinct from and opposed to beauty, whereas this is very far from being the case; for although there is an extensive class of objects which are disagreeable in reality, and which yet become attractive in representation, where they are divested of all that renders them physically repulsive (such as beggars, hovels that seem the abode of penury and filth, &c.), there are likewise numerous others which, while they are beautiful in themselves, are far from being deficient in picturesque quality. It is true there are also not a few that are eminently delightful or beautiful in nature, yet become insipid in representation; but that is because they are deficient in that variety of colour and form which painting demands. A level well-kept lawn presenting a uniform surface of rich verdure is beautiful, that is, excites lively pleasurable emotions, but it is so far from picturesque that it is generally made use of as an argument to prove that neatness and smoothness are incompatible with picturesqueness. Such an object undoubtedly, when transferred to the canvas, and made to occupy a prominent place in the composition, does not produce a good effect, inasmuch as it then shows only as a monotonous surface of nearly unbroken green colour: but if we break its uniformity of surface by figures, by shadows, by gleams of light, by gradations of hue, and make it duly subordinate to the objects placed upon it, though it will still convey the idea of being a level piece of grass, it will be divested of its monotony, and may even become picturesque, if it should produce a good contrast to other parts.

The same theory holds true with respect to *form*, it being by no means correct that objects are picturesque in proportion as they are irregular and devoid of symmetry; though, as before said, the painter, whilst maintaining the appearance, gets rid of the formal presentation of symmetry. Thus, of a piece of regular architecture: if it be shown merely in elevation, a structure which is symmetrical will produce a stiff and inartistic appearance; but on the contrary, by means of judicious foreshortening or perspective, of shadows thrown upon it so as to break up the too great equality of its masses, and by means of figures and other accidents, it may be made to present an agreeable species of irregularity to the eye, at the same time that it suggests to the mind the idea of the most perfect symmetry.

Although, therefore, the term picturesque is often applied, by way of distinction, to that class of objects which are well suited for painting, but possess qualities more or less disagreeable in themselves, and so far implies something distinct from if not absolutely opposed to beauty, it comprehends also another class, which, while they are beautiful in themselves, require to be accommodated to pictorial representation, inasmuch as, in order to produce their images upon canvas, there must be great contrasts and irregularities, both in respect of form and colour. The truth probably is, that while every object may be, under certain circumstances, admissible into a picture, and by means of proper artistic treatment be so far rendered agreeable to the eye as to be then properly termed picturesque—yet there are particular objects which by their forms or surfaces are suitable for representation as leading features in a picture, without that artistic modification which more formal objects require, unless they be introduced as mere accessories: and hence these are not improperly distinguished by the term picturesque.

PIEPOWDER COURT. By the common law every owner of a fair or market is bound to hold a court for the decision of matters arising therein, which being instituted principally for the convenience of the itinerant dealer, was called in Norman French 'pied pouldreux,' the court of pipowders, "curia pedis pulverizati." The court is held before the owner of the fair or market, or his steward, who, by 17 Edward IV. c. 2, is prohibited from entertaining any action unless the plaintiff or his attorney swear that the cause of action arose within the precincts and during the time of the same fair or market. Before that statute these courts appear to have emulated those of Westminster Hall in seeking to extend their jurisdiction; and in the preceding reign, W. Larke, the servant of a burgess coming to the parliament, was arrested in the fair of the abbot of Westminster. He was transferred by his creditor, Margerie Janyns, to the Fleet, where he remained till, by the interference of the House of Commons, he obtained his discharge. (4 Rot. Parl., 357.)

This court in its turn has been gradually encroached upon by the superior courts, and is now fallen into total disuse. (See Blackst. 'Com.,' vol. iii., and Mr. Morley's account of Piepowder Court, vol. vii. of 'Notes and Queries,' new series, p. 495.) A book is deposited in Guildhall library, in the city of London, the last entry in which is, "September 2, 1854—The lord mayor not having proclaimed Bartholomew-fair, the court of piepowder consequently was not held."

PIER (from the French *pierre*, stone) the general name for the solid spaces between a series of openings in a wall, whether windows or arches; but in its technical meaning the term is more particularly applied to the pillar-like masses of masonry or brick-work from which arches spring, rising from what is termed the *impost* capping the pier, and which generally consists of a series of mouldings, although sometimes it is merely a platband, and occasionally the impost is omitted altogether, especially in rusticated basements.

Piers are frequently decorated with either pilasters or engaged columns. In many instances columns are substituted for piers, placed either singly or in pairs; and the arches spring either immediately from their capitals or from an entablature over them. There are again many examples in which both piers and a lesser order or sub-order of columns are employed, the latter being insulated on each side of the pier, and their entablature forming the impost from which the arches spring. Palladio's Basilica, or Palazzo di Ragione, at Vicenza, affords an example of the kind, in which the faces of the piers themselves consist of a larger order in half columns, so that the whole composition resembles a series of what are termed arched Venetian windows entirely filling up the spaces between the larger columns. Besides these and other modes of decoration, niches are occasionally introduced as ornaments to piers.

In Pointed Gothic architecture the insulated piers supporting what are distinguished by the name of pier-arches are not rectangular in plan, but splayed off or turned diagonally. Early English, or First Pointed piers, as at Salisbury, frequently consist of an insulated cylindrical column, surrounded by slender detached shafts, all uniting under the same capital; but sometimes the central column is octagonal or square. In Middle Pointed or Decorated churches the pier is frequently formed of four semi-cylindrical shafts united together; sometimes of eight shafts joined together, four large and four small, either plain or filleted up the face; in some cases it resembles a cluster of slender shafts united on a lozenge plan: but many varieties occur, though almost invariably the smaller shafts are attached instead of being detached as in the preceding style. The Third Pointed or Perpendicular piers are commonly in section a square or parallelogram with the angles splayed or cut in a deep hollow; or else they are often moulded shafts, which latter are sometimes a continuation of the mouldings forming the arch, carried down without any interruption by capitals or horizontal mouldings to the shafts, yet sometimes terminating below in moulded bases; at others *dying into* or uniting with the plain surface forming the footing or general base of the pier. [GOTHIC ARCHITECTURE.]

The term pier is also applied to the solid masses supporting the arches of a bridge; with the exception of the extreme ones, which are distinguished by the name of abutments. [ABUTMENTS.] The piers of bridges have no impost mouldings, and they are carried quite through the structure, their depth being equal to the breadth of the bridge itself from the parapet on one side to that on the other.

Pier is likewise the name given to a mole or jetty carried out into the sea. See the article PIERS.

PIERRIER was the term originally applied to an engine for casting stones; then to a small kind of cannon used with stone shot. It is now generally applied to a description of mortar for throwing stones, and also to a fougass [FOUGASS] loaded with stones made for the protection of breaches, &c., to be fired when the assaulting column approaches.

PIERS, *of Harbours and of Landing-Places.* In the artificial harbours formed upon the shores of bays or roadsteads, it is often necessary to execute a defensive mass of stone-work, or occasionally of timber, either for the purpose of securing the tranquillity of the harbour, or of providing the means for landing goods and passengers from ships which require a considerable depth of water. These works are known by the names of *piers* or of *jetties*, and their construction involves some of the most interesting questions of the science of marine hydraulic engineering, on account of the mechanical difficulties of their execution, and of the influence which every change in the outline of a sea-shore must exercise upon the relative conditions of the tides, currents, and alluvial deposits which take place on that shore. It would seem, from these remarks, that the most important points to be discussed in designing any work of these descriptions are—1, the directions to be given to them in plan; 2, the technical methods of their execution; and 3, the precautions to be taken to prevent, or the methods to be adopted for removing, any accumulation of alluvial matters caused by the erection of the piers.

1. Before entering upon the consideration of the details of piers or jetties, it may be observed that their execution is only desirable when the port they are intended to serve is situated in a bay which is naturally sheltered from the extreme violence of the sea. There are, no doubt, many harbours formed upon exposed coasts where the piers are made to inclose, at once from the sea, an outer harbour, leading to still water inner basins; as, for instance, at Ramsgate, Dieppe, &c. But

however the piers of such harbours may be placed, there must always be so great a danger of a ship missing the entrance in a storm, and the agitation of the waves in the outer harbour, at such periods, must produce such an amount of injury to the lock-gates of the inner harbour, that it may be laid down as a general rule that no safe harbour, no real harbour of refuge, can ever be formed on an open shore.

Assuming, however, that the position selected for the erection of the piers of a harbour is properly sheltered from the violence of the open sea, the direction of the piers themselves must be such as to allow the current of the flood-tide to assist in carrying a ship into the fair way of the channel; and the general practice appears to be in favour of their being placed so as to form an angle of from 12° to 20° to the direction of the prevailing winds, although local circumstances may, and often do, require that the latter law should be modified. If the sea should be exposed to the action of the wind to such an extent as to be very rough in stormy weather, the piers must not be built in straight, or even in long, circular, or elliptical lines; because in that case the agitation of the open sea would be transmitted to the inner harbour. But when the outlines of the piers, in plan, are made polygonal, the agitation of the sea may be reflected from side to side, and thus reach the inner harbour in perhaps a more dangerous manner than even in the case of the straight walls, because the waves will be more irregular, and will interfere greatly with the steering of the ship. It would appear that the system adopted in the construction of the jetties of Dieppe and of Havre, in both of which ports wooden breakwaters are inserted in the line of the piers (the latter being polygonal in plan), is the one most fitted for harbours in exposed situations; whereas, in sheltered positions, either straight or curved piers may be resorted to.

One of the most important functions piers are designed to perform being to facilitate the movements of the shipping resorting to a harbour, it is advisable in designing them to dispose their plans so as rather to facilitate the entry than the departure of vessels; because a ship in harbour can always wait for a favourable condition of circumstances, whilst a ship entering may be compelled to do so under stress of weather. Under these conditions, the entrances are disposed so as to allow the current of the flood-tide, or the inshore currents, if no marked tides should exist, to carry the ship into the fair-way channel, without exercising any influence likely to carry the ship against the jetty walls. As to the length to be given to the piers, it must be regulated, firstly, by the distance of the deep-water line from the line of the shore; secondly, by the set of the currents; and thirdly, by the means used in the particular port for hauling out the vessels. This latter practical detail of navigation will be found especially to affect the respective lengths of the piers, when two are used; because when the outgoing vessels are hauled by men, or warped by ropes, the pier which serves for those operations must be made sufficiently long to allow the vessel to make her first tack without any danger of her falling off against the opposite pier. As a general rule, it is preferable to make the pier under the prevailing wind longer than the other one; but local circumstances may at times render it necessary to modify the application of this law.

The width to be given to the channel between the two piers of harbours, where such double works are required, should be at least such as to allow three ships to enter at the same time, under full sail; and this width may vary between 100 and 250 feet, according to the class of vessels frequenting the harbour. At the heads of the piers the widths of the channels should be increased, because the ships entering require more room for their evolutions when under the influence of the way they bring in from the open sea than they do when they have followed the narrow channel for some time. The general use of steam-tugs, by enabling several vessels to leave at the same time, seems to have rendered it desirable to increase the width of the channels.

In river-piers, and in landing-stages, the only considerations which affect the plan to be given to the structures are, the depth of the water, and the possibility of the transmission of the agitation from the open sea, or of the local agitation produced by the action of the wind upon a large surface of water. The latter phenomenon, as is well known, depends on the depth quite as much as on the extent of the water-surface over which the wind blows; and it is for this reason that, in broad deep rivers, such as the Southampton Water, the piers are made curvilinear in plan, in order to inclose and protect a species of port; whilst on the shallow shores of the Thames, at such places as Southend, a straight pier is found to be sufficient for the real necessities of the locality. The peculiar range of the tides at any particular place may render it necessary to vary the means adopted for facilitating the loading and unloading of ships; but a study of the various landing-stages on the Thames will teach the student far more on this subject than it would be possible to do within the limits of this article.

2. As to the technical methods of constructing piers, they must evidently be regulated by the nature of the building materials furnished by the locality; and those structures may either be formed of wood, concrete, loose rubble stone, or solid masonry bedded in mortar; they may be either perfectly closed on the water-line, or open, so as to allow any littoral current to sweep through them.

When wood is used, the foundations intended to receive the upper structure require to be executed with great care, and in such a manner as to allow the said upper structure to be repaired with ease, and without affecting the foundations; for it is essential to bear in mind, that the shock, or the abrasion, produced either by vessels, by waves, or currents, and that the ravages of the *Teredo navalis*, or of the *Limnoria terebrans*, are most injurious to the parts of a wooden pier placed between high and low water-mark. All those parts must, therefore, be easily accessible, and renewable, either separately or entirely, as may be required. It is customary to execute wooden piers with piles and whaling-pieces, fixed below the level of the ground of the foreshore, and upon these a series of trapezoidal frames, carefully braced and bolted together, are placed. The lower part of these frames is covered with loose rubble, concrete, or fascines, in order to protect the foundations.

In open wood piers the frames are fixed at distances asunder of from 6 to 10 feet in the sea, according to the depth of water, and the habitual agitation of the latter at the place considered. The frames are made in the form of a trapezium, the inclined sides being respectively turned towards the open sea, or towards the sheltered channel, and forming an angle of from 13° to 33°, with a vertical line passing through their points of junction with the sill pieces. According to the width intended to be given to the roadway of the pier, the frames are made with one or more upright posts, between the inclined sides, and the whole are retained in their places by cross ties and raking braces converting the parts of the assemblage into a series of triangles, the sills and heads forming with the inclined sides the outer lines of the frames. Longitudinally these frames are connected by whales, stringers, and by the joists of the platform, and upon the latter the planking of the road-way of the pier is laid; this planking is formed of rather narrow timber, about 4 or 5 inches thick, laid with intervals of about 1¼ or 1 inch. The planks are spiked down upon the joists, but upon their ends they are clipped by a bridging joist, bolted to the longitudinal sill fastened to the frames; sometimes this bridging joist also bears a handrail of open timberwork. Tenon joints should be avoided in the carpenter's work of the frames, and under no circumstances whatever should the planking of the roadway be laid water-tight.

Should the wooden piers be filled in with rough stonework, the latter material will be retained by means of close boarding laid horizontally against the upright posts of the framing; and when that planking is carefully laid, the interior may be filled in with shingle, sand, or clay, or with concrete made with a hydraulic lime basis. It would appear that the best position for the planking, under these circumstances, is upon the outside of the frames; for although unquestionably, the planks would resist the tendency to displacement, from the weight of the filling-in material, more efficaciously if they were nailed upon the inside than if they were nailed upon the outside, yet in the latter case the framing would be far more efficaciously protected from the action of the waves, and it would be much easier to repair any accidental damage. The essential condition in all these cases is, in fact, that the substantial framing should be withdrawn as much as possible from the direct action of the sea; and that those parts, which are exposed to it, should be susceptible of being easily replaced.

The advantages of wooden jetties consist in the economy of their construction; but in practice it is found that the repairs of such work are so frequent, and so costly, that the use of wood should be only resorted to when it is utterly impossible to resort to the use of more durable, even though originally more expensive materials. Open wood piers have, however, another occasional advantage, namely, that they do not seriously interfere with the advance of any littoral current, and therefore they are not so likely to produce any change in the outline of the shore, by producing a deposit of alluvial matters, as a solid pier would do. In the landing stage lately erected at Margate an attempt has been made to unite the advantages of open piers with greater durability, by the use of cast iron piles; but it would be desirable to watch the effect of sea water on the iron during some years, before passing any opinion on the merits of this system. It may be added that the use of creasoted timber, for works exposed to the action of the sea, seems to have removed some of the most serious objections to the use of that material; for not only has this process increased the durability of the wood, but it would appear to constitute also an efficient protection against the teredo. Whether wood or iron piles be used, it is necessary to guard against the percussive action of the ground swell upon their heads; and it is for this purpose that the layer of concrete, rubble, or fascines, over the foundations is introduced.

Stone piers are either executed of loose rubble thrown down and allowed to assume its natural slope by the action of the waves; or of ashlar masonry external walls bonded together so as to form a series of cases filled in with concrete, or with rubble masonry, or with a hearting of earthwork protected by dressed masonry walls; the determining motives for the selection of either of these modes of execution being, of course, merely economical ones. The most difficult part of such structures consists in their foundations when executed at some distance from the shore, and in deep water, where caissons, or coffer dams cannot be used; especially if any strong littoral currents should exist in the particular locality. The very successful manner in which the new graving dock of Toulon was entirely constructed of concrete, under a head of water of not less than 37 feet, proves that it would be possible to make a much greater use of that material than is usually done in England; but of whatsoever material the piers may be formed, the necessity for protecting the foundations from the undermining actions of the currents, or of the ground swell, must remain the same. The other practical remarks to be made with respect to the execution of masonry piers are, that they must settle equably throughout their whole mass; that no openings should be left by means of which water could get into the interior, either directly, or by syphonment; that the masonry should be protected against the abrasion of the alluvions carried forward by the currents, and that the ships lying alongside the piers should not bear directly against the face of the masonry, for which purpose fender piles are used; finally, all abrupt projections must be avoided whether in the plan or the elevation of the piers, and the surface of the roadway must be carefully laid, so as to throw off all the water which may break over the piers. It is usual to make the width of the roadways in the body of the work, from 10 to 28 feet, and to increase that width, at the heads, to from 30 to 50 feet; the body of the pier being kept about 10 feet above the level of high spring tides, and the heads about 12 feet above the same level. Generally speaking, a lighthouse is erected near the extremity of a pier; fog bells and signal guns are fixed; and the necessary bollards, or mooring posts, reeving pullies, capstans, and landing staircases are to be provided. It is curious that the softer calcareous stones are nearly as much affected by the boring mollusca as wood is affected by the limnoria and teredo; and that the solenidæ, pholidæ, and lithodomi, exercise fearful ravages upon that class of stones in some places. Where those animals abound, or where the littoral currents carry forward much alluvial matters, it becomes necessary to employ the more resisting siliceous rocks, or the granites.

3. The questions connected with the interferences likely to be produced by the erection of a pier upon the outline of a coast are often of extreme importance, not only to the harbour it is desired to create, but also to the whole of the surrounding district; and they must, therefore, be very carefully and attentively studied before such works are commenced. Unless there should exist some local cause of disturbance, it will, in fact, be found that the alluvial matters detached from cliffs and sea-shores by the action of the sea, will be carried forward by the flood-tide until they meet with some impediment able to check their advance; they then begin to accumulate behind this shelter until the angle is filled in, when the onward progress of the alluvions is resumed. If the littoral current should sweep across the mouth of the pass between the piers, it may carry the sand and shingle past the latter; but under almost all circumstances a large portion of the finer matters in suspension will be carried into and serve to silt up the harbour. The same thing will occur with a few trifling modifications when single solid piers are carried out from a shore, whether their plan be straight or curved, or whether they be constructed in the sea or in rivers; the alluvial matters will accumulate on the upside to the current, and it often happens (as it did lately at Dover) that, until the advance of the shingle again brings some light moveable materials to protect the fore-shore, the newly-created counter-current will wear away the original outline of the coast on the downside of the pier.

The Roman engineers appear at an early period in the history of engineering, to have recognised the importance of these laws, and they constructed their ports habitually upon a series of open arcades, with the avowed intention of interfering as little as possible with the advance of the littoral currents. In modern times the use of wooden or of iron open jetties has been recommended for the same purpose; but all these methods of palliating the evils of the interference with the progress of the alluvions are open to the serious objection that they leave the interior of the harbour without protection from the undulations of the open sea; and it therefore follows that if the commerce of the harbour should be important, the piers should be rendered sufficiently solid to intercept the normal deposition of the alluvions, even on the condition of constructing defence works for the shores on the down side. Any materials which, under these circumstances, may be carried round the heads of the piers must be removed, either by means of dredgers or by periodical sluicing. [SLUICE.] The practice of the most scientific engineers of the present day, it may be added, tends towards the use of dredgers in preference to sluicing; both on the score of economy and of efficiency. When the alluvial matters are removed by sluicing they are in fact only carried to the distance which the transporting power of the water can command; and then they almost always are thrown down in the form of a bar, across the mouth of the harbour. It would really appear that, under these circumstances, it is wiser to provide for the extraction of the alluvions by machinery, proportionate to the quantity brought in within certain definite periods; especially as it would then be easy to construct the piers in plan, solely with reference to the physical conditions of the locality as affecting the navigation, instead of (as in the case of resorting to sluicing) building the piers for the purpose of guiding the outpouring waters.

Lamblardie is the engineer who has studied the question of the advance of alluvial matters on a sea-shore with the most skill, attention, and success; and it is to his works, or to those of Zendrini, or of Sir H. Delabeche, that the student of this subject must be referred. The leading principles of this branch of the science of hydraulic engineering, so far as they are likely to affect the construction of piers or harbours, may, however, here be stated briefly as follows—allowance of course being made for local causes of disturbance.

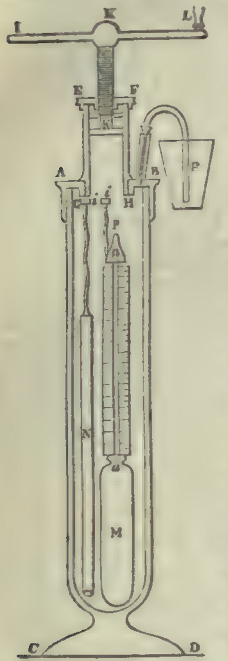
At the base of steep cliffs the alluvions follow the outlines of the coast, and they have, under ordinary circumstances, but little tendency to change their positions; in deep bays they will assume a curvilinear outline, whose concavity will be turned towards the sea in the direction of the prevailing wind, unless where modified by the line of the current. If the directions of the prevailing wind and of the current should be parallel to the shore, the transporting power of the current to carry forward alluvial matters will be less than when the direction of those forces assumes an angle of 45° to the coast; and when the wind blows perpendicularly to the shore, the waves may exercise a great effect in abrading the latter, but the movement of the alluvions will be almost imperceptible. A bay, or a harbour, whose axis may be in the line of the prevailing wind will, therefore, be exposed to become rapidly silted up; and this result will take place with increased rapidity if any land waters bringing down matters in suspension from the uplands should discharge themselves into the bay. One important remark to be made with respect to the deposition of alluvial matters in the embouchures of rivers receiving the flood-tide, under circumstances which should allow the latter to carry forward the shingle it previously detached, is, that the alluvions so carried in are of far more serious importance in their effects upon the accumulations around piers or harbours constructed in those rivers than are the alluvial matters brought down from the uplands. There is, in fact, every reason for believing that in such rivers as the Thames, the Seine, or the Rhine, more alluvial matter is carried in from the sea than the land floods can transport to their respective mouths; which, it may be added, is another reason for constructing open piers in such situations, because they offer less resistance to the natural laws of such localities. After all, engineering is essentially the science of adapting the means to the end desired; and economical conditions of first outlay may often render it expedient to depart from the strict application of even strictly demonstrated laws; but the attempt to run counter to those laws will always be productive of disastrous results; and in no case is this more true than with regard to the effect of piers upon the outline of a coast. The histories of Ramsgate, Dover, Calais, or Dunkirk harbours, or of the ports, so called, of refuge on our eastern coast may be referred to as illustrations of this remark.

The Brighton chain-pier may be referred to as an illustration of an ingenious method of constructing works of this description without producing any interference with the movement of the alluvions; but piers with such wide intervals between the points of support give no protection from the agitation of the waves.

PIETISTS, the name given in the 17th century to a kind of German Methodists or Evangelicals, who, being members of the Lutheran Church, were dissatisfied with the cold dogmatism of the generality of its clergy, and felt the want of a revival of religious feeling and of practical piety and charity. Without separating themselves from the church, they instituted meetings called "Collegia Pietatis," from which the denomination of Pietists was derived. Philip Jacob Spener, a divine of the Lutheran Church, who was preacher at Frankfort and afterwards at Dresden and Berlin, was the chief promoter of these meetings, which began about 1670. [SPENER, in BIOG. DIV.]

PIEZOMETER (*πιέζω* and *μετρεω*). Under ELASTICITY are noticed the various attempts to measure the compressibility of water and other fluids, and reference is made to Professor Oersted's instrument by which the problem was satisfactorily solved. It consists of a strong glass cylindrical vessel A B C D with a smaller cylinder A B E F screwed into the top, containing an air-tight piston K worked by a screw; M is a glass bottle, into the neck of which is ground a capillary tube *a a*, open at both ends, of fine bore, and each inch of its length must express a precise fraction of the contents of the bottle. This is done by weighing how much mercury the bottle will hold, and how much an inch of the bore of the tube. In some of Oersted's tubes each inch in length was found to hold $\frac{80}{1000000}$ths of the contents of the bottle. Let us now suppose the whole of the apparatus to be filled with water: any pressure upon it which causes its surface in the tube *a a* to descend one inch, will have compressed it by $\frac{80}{1000000}$ths of its bulk. The scale attached to the tube was graduated, each inch into 40 parts, so that a depression of the water in the tube through one of these divisions would indicate a compression of two millionths. The apparatus being arranged as in the figure, only with the piston K at the bottom of the short cylinder in contact with the water which fills the large cylinder and the bottle M, the piston is screwed back towards E F, and as it recedes water is drawn into the vessel by the siphon B P from the vessel P. A cock is then closed in the siphon, and on screwing the piston downwards the pressure is propagated through the water in the cylinder, and also through the tube *a a* to the water in the bottle, such pressure being of course precisely the same within and without the bottle. A separation is made between the water in the tube *a a* and that in the large cylinder, by means of a bead of air contained in the glass cap P, which yielding to the pressure descends the tube *a a*, and serves as an index finger to the scale. The amount of pressure applied by driving down the piston is measured by means of the tube

N, which is closed at the top, open at the bottom, and graduated into equal parts. It has a ring of lead at the bottom to keep it immersed, and being full of air it readily indicates by its compression the amount of pressure applied to the water by the piston. By the law of Marriotte [Elasticity], the diminution in the bulk of aeriform bodies is proportional to the pressure, so that by observing the degree to which the air is compressed in the tube by the rise of water in it, the pressure exerted by the piston and that sustained by the water in the bottle is always known. In this way it was ascertained that water is compressed 46$\frac{1}{10}$th millionths of its bulk for every atmosphere of 15 lbs. on the square inch. Of course by filling the apparatus with some other liquid its compressibility could be ascertained, and taking mercury as unity in millionths of an inch, alcohol was found to be 20, sulphide of carbon 30, water 46·1, sulphuric ether 60.



The results obtained by Messrs. Colladon and Sturm differ considerably from those of Oersted. Those physicists state that a correction should be made for the compression of the substance of the tube and bottle, in consequence of the pressure sustained by them within and without. M. Poisson has given a simple rule for this correction, the necessity for which is denied by Oersted, who states that the recession of water in the capillary tube is about 1½ millionths greater when bottles of lead and tin are used instead of bottles of glass. Piezometers with bulbs of different materials, filled with some liquid of known compressibility, have been used for ascertaining the cubic compressibility of the material of the bulbs. Thus it has been ascertained by Professor Forbes, that the cubic compressibility of caoutchouc is about the same as that of water, for when a piezometer with a caoutchouc bulb filled with water is compressed, the index remains nearly stationary in the stem.

PILASTER. [Column.]

PILE. [Galvanism.]

PILE. A piece of timber, or of iron (either cast or wrought), driven into the ground for the purpose of acting in the manner of a column, to transmit the weight of a superincumbent structure to an inferior resisting stratum, when the surface stratum is of so compressible a nature as to be unable to support the weight intended to be put upon it, and is so thick that it cannot be removed. Piles may be used either in water, or on land; and they may be used either isolatedly, or in close rows, retaining strictly the name of *piles*, in the first case, or those of *gauge piles*, *whole piling*, or *sheet piling*, in the latter. The gauge piles are those driven to mark out the position the close piling is intended to enclose; the whole piling is a close enclosure of whole baulks of timber; and the sheet piling is a similar enclosure formed of half baulks. When cast-iron piling is used, the gauge piles are made with grooves on the side, into which plates with stiffening ribs are inserted; whereas in the case of wood piling, the close piling is made, in the best description of works, with grooves and tongues, and is kept in its position by being driven between whaling pieces, or horizontal ties.

The descriptions of wood used for piles, in England at least, are beech, elm, larch, Baltic fir, rock elm, live oak, green heart, and the sabacu from Guiana. Of these woods the beech decays rapidly when exposed to alternations of dryness and of humidity, but it resists well when constantly immersed; elm resists changes of condition more successfully; and fir, when free from sap, is still more durable; the American hard woods, such as the rock elm and live oak, are preferable to the soft woods when the piles have to be driven into hard gravel, and they appear to be very durable; and it may be observed that the green heart and the sabacu have been used to a great extent on account of their supposed immunity from the attacks of the teredo. It is, however, now ascertained that those destructive creatures will attack the green heart with nearly as much readiness as they will attack any other kind of wood; and inasmuch as the lymexylon attacks the green heart on land, there can be little *à priori* reason for supposing that the limnoria should avoid it in the water. In fact, the result of all the enquiries or experiments which have been made with respect to the value of the processes for the preservation of piles, or to the unassisted resistance of woods in such positions, has hitherto been to show that nothing but the careful injection of creasote is able to prolong, even temporarily, their durability. As the boring worms, however, do not attack wood which is entirely buried in the ground; and as the durability of the wood itself is infinitely greater when it is protected from the action of external atmospheric influences by being buried; the common sense of the use of piling appears to be to carry the solid masonry or concrete foundations below the ground line, so as to ensure that the piles shall always be covered.

Wooden piles are generally pointed and shod with iron at the lower end, and they are temporarily hooped at the top, in order to prevent their heads from being split or beaten up during the operation of driving. Occasionally piles are driven with their broad ends downwards, when foundations are required to be executed in soft mud of indefinite thickness, as in the case of the port of L'Orient. It is considered that in such cases, the piles only act to resist compression by the friction developed upon their surfaces, and that their resistance is only equivalent to about 45 lbs. per foot superficial of those surfaces; but in addition to this small amount of resistance, piles, such as are thus described, are exposed to the great inconvenience of being likely to be deflected from the perpendicular by any subsequent compression of the subsoil. If, however, such a mode of driving piles be resorted to, and indeed in almost all cases of piled foundations, it is advisable to commence with the outer rows, and to drive inwards, or towards the centre of the mass, in order to compress the enclosed ground as much as possible under the seat of the intended foundations. Of late years, the introduction of the Mitchell's screw piles has greatly facilitated the execution of works of this description, in homogeneous and soft foundations; but they do not act in any way to compress the ground, and are of more use for the purpose of fixing piles intended to resist lateral strains, than for driving piles intended to resist vertical weights.

In calculating the weight a pile should support, it is not customary to take into account the assistance it receives laterally from the ground into which it is driven; and the number of piles, and the load to be brought upon them are ascertained upon the supposition that they must be able to support that load if they were really isolated; or in other words, the longer the pile the less must be the weight it is made to bear. Rondelet, in his 'Art de Batir,' gives a series of tables of the respective weights which may safely be brought upon piles of variable ratios between the diameters and height; and it may suffice here to say, that when that ratio does not exceed 16 times the diameter, Rondelet considered that the load brought upon the pile *permanently*, might safely be carried to between 430 and 500 lbs. per inch superficial of the sectional area. Morin, after verifying Mr. Eaton Hodgkinson's tables of the resistance of columns to compression, increased the value of the resistance of piles; and the proportionate (permanent safety) loads to be brought upon them are considered at the present day to be nearly as follows:—

Ratio diameter . .	12	14	16	18	20	22	24	32	36	40
Weight in lbs., per inch superficial	629	596	559	525	496	464	426	312	271	218

When piles are being driven, they should be made to advance so far into the earth that the effort exercised upon their heads, or the driving weight, should virtually exceed the statical effect of the intended permanent load; and when this is attained, the pile is said to have attained *its refusal*. There are no recorded experiments upon which to found a theory for ascertaining the conditions regulating the descent of piles; and therefore, the rules for fixing their refusal must be considered as being simply empirical. It is, however, customary to consider that a pile has attained a satisfactory refusal, if it be intended to support 25 tons, and will not descend more than ⅜ths of an inch, under a series of 30 blows from the monkey of a ringing engine, weighing 12 cwt., and falling a distance of 4 feet; or under a series of 10 blows from a monkey of the same weight falling a distance of 12 feet; if the weight be reduced to 12½ tons per pile, the refusal is diminished to ⅝ths of an inch; and if to 5 tons, to 2 inches. At the bridge of Neuilly, where the piles support a weight of 52 tons each, Perronet adopted a refusal of 1-5th of an inch for a series of 25 blows with a 12 cwt. monkey falling 4 feet 8 inches. It is important to observe, in all these cases, that the piles may often appear "to refuse," after having been struck by frequent blows succeeding one another rapidly, perhaps on account of the superinduction of a state of vibration in either the piles themselves, or in the ground; and that if the driving be recommenced, after an interval long enough to allow the vibration to cease, the pile will begin to descend again. In practice, therefore, no pile should be considered to have attained its refusal, until the trial has been repeated at the interval of at least one day after the first observation upon its conditions of descent.

In regularly piled foundations, it is now the custom to surround the heads of the piles with concrete, to a depth of three feet below the timber platform, and to extend the concrete at least three feet beyond the outer line of the piles. The platform is usually made of two courses of planks, the lower one tenonting upon the pile-heads, and the upper one halving upon the lower. The whole of this timber is again buried in concrete to a depth of two feet above its uppermost surface. It is sought, in cases where these precautions are taken, to render the whole of the foundation homogeneous, and to guard against any lateral displacement by the piles turning over on their lower external edges, an accident which often occurs when a lofty quay wall is built upon a compressible subsoil; and although the precautions may be costly, the result of the works executed in many of our own, and in many foreign, sea-ports, proves that they cannot safely be dispensed with.

PILE-ENGINE. The machinery used for the purpose of driving piles is rather varied; but it is only within a very few years that it has assumed anything like a scientific character, or has admitted the application of any mechanical power other than mere brute strength.

The pile-engines which are still used in countries behind the spirit of the age in the development of the mechanical arts, such as Holland, Germany, Spain, or Italy, are the old fashioned ringing engine, in which a monkey, or a large hammer, is raised by means of a pulley and a rope, the latter being connected with a great number of cords, which are pulled in unison by an equal number of men. The weight of the monkey of these machines is usually about 10 or 12 cwt., and the fall is only from 4 feet to 4 feet 8 inches; and in practice it is found that the dynamical force, thus brought to bear upon the piles, is not sufficient to drive them through grounds of any notable degree of resistance; the ringing engines, moreover, require so much space, and so great a number of men, as to render their use extremely inconvenient when numerous piles have to be driven in a small area.

In England and in France the pile-engines generally used consist of a vertical frame of about 24 feet, or at times 30 feet, in height, bearing at the top a pulley, over which passes a chain starting from a crab fixed on the ground, and able to reach a monkey resting, when the machinery is in repose, on the pile head. When the pile is being driven the monkey is raised until some fixed pins open the clutch which supports the monkey, and the latter then falls on the pile head; the usual weight of the monkey is from 12 to 16 cwt., and the fall varies from 12 to 18 feet, according to the resistance the pile meets with in its descent; occasionally the fall may be extended to 26 feet, and the crabs are often worked by steam, when the number of piles to be driven within a given area is considerable. The principal objection to the use of these engines consists in the danger which must exist of their splitting the piles, either by turning the shoe, or by the development of cross fissures, from the enormous force of the blow produced by a great weight falling from a great height; but at the same time the rate of advance they produce is very rapid, and they are economically worked.

The various systems for sinking piles by pneumatic pressure have not hitherto succeeded well, when applied to piles of the dimensions ordinarily used, although their results have been satisfactory when large cylinders have been used. At the present day these systems have been almost entirely abandoned; and when it is necessary to sink even large hollow cylinders, to a very great depth through light soil, the use of caissons working with compressed air, in the same manner as was done at the Rochester or the Saltash bridges, has been substituted for the costly and partially inefficient methods of pile driving by pneumatic pressure. In fact, the latter system consists in creating a vacuum beneath a surface exposed to the air, and the weight of the atmosphere in excess of the weight of the enclosed air is supposed to cause the pile to descend; but it frequently happens, that in proportion as the internal air is withdrawn, so does the moveable ground beneath it follow into the open space; and by thus compressing the air in the interior it annihilates the difference between the two pressures. Whereas, when the compressed air is used, a fresh quantity is pumped into the interior of the cylinders until it attains a pressure of about 60 lbs. on the square inch, which is sufficient to prevent any running sand, or semifluid mud, from rising under ordinary hydrostatic pressure at least. But it must be repeated that either of these systems is adapted to sinking caissons rather than piles, although they might originally have been applied to the latter.

The Mitchell's *screw-piles* are so called, because they are made with the worm of a screw at their extremity, and they are driven by turning them in the ground in precisely the same manner as an ordinary screw is driven into wood. It must, however, be evident, that piles so driven do not compress the ground in any appreciable manner; and that they do not furnish any direct evidence of the amount of resistance they offer to vertical compression. The Mitchell's piles are admirably adapted to resist efforts of tension, as in the case of the dead works of a floating buoy, or of a hauling lump, or mooring block; because the whole prism of earth around the screw must be torn out before they can move, and the same condition renders them equally fitted for the piles of piers driven into tolerably firm and even soils, which piers are exposed to cross seas, but are not exposed to heavy vertical weights. The easy descent of the Mitchell's piles, and the absence of vibration whilst they are descending, may, in many practical instances, constitute a great recommendation for them.

The most striking illustration of the adaptation of machinery to pile driving, is perhaps the application of the Nasmyth's steam hammer to this purpose. In this case the steam is admitted into the bottom of a cylinder bearing a piston-rod connected directly with the monkey, so as to raise it vertically until the piston reaches the head of the stroke; the steam then escapes, and the piston falls. The weight of the monkey in these engines need only be limited by the capacity of the cylinder, or by the elasticity of the steam; and it is in practice made to range between 32 and 45 cwt.; but the height of the fall is limited by the length of the stroke, and it rarely exceeds 2 feet 6 inches. In the ordinary pile engines, the number of blows does not exceed 35 or 40 per hour; but with the Nasmyth's hammer it is easy to increase that number to between 50 or 60 per minute. It follows from the dynamical conditions of this engine, that in ordinary clays, sands, or alluvial deposits, where the resistance to the descent of the piles is not very great, and is tolerably uniform, that the Nasmyth's pile-engine drives piles with a rapidity far greater than any other machine hitherto applied to such a purpose; but when the resistance becomes considerable, the piles are very much exposed to be beaten up, to be set on fire, or to be broken by the frequent blows; or if those results should not occur, they may be set into such a state of vibration as to oppose a serious resistance to their descent. The writer of this article has actually seen 5880 blows struck in 1¾ hour upon a 14 square pile, by a monkey of 42 cwt. falling 2 feet 6 inches, without causing it to advance more than 3 inches; but the head of the pile was literally beaten up into a sponge: an ordinary pile-engine with a monkey of 16 cwt. falling 18 feet, would, in six hours, have produced a greater dynamical effect under far more advantageous conditions. The use of the Nasmyth's steam pile-driver should therefore be limited to the class of soils above-named; but in driving through hard gravel, or tufaceous limestone, the monkeys with large falls and slower action should be used: in fact, the mechanical effect produced by a weight falling on the head of a pile is such that the descent of the pile is proportional to the fall of the monkey; and it is admitted that economically there is an advantage in the adoption of heavy monkeys falling through heights ranging between 12 and 20 feet. It has been shown, by direct experiment, that the descent of a pile is proportional to the mass of the monkey, added to that of the pile, multiplied by the square of the common velocity of those two bodies after the shock. For if the mass of the monkey be represented by m, and that of the pile by m', the common velocity of the monkey and of the pile by u, and the velocity of the monkey before the shock by V, the descent may be derived from the following formula:—

$$(m+m')\,u^2=(m+m')\,\frac{m^2V^2}{(m+m')^2}=\frac{m^2V^2}{(m+m')}$$

but as in this case $V^2=2gh$, in which $g=$ the accelerating force of gravity (32⅙ feet in London), and $h=$ the fall of the monkey, the descent of the pile is proportional to $\frac{2gm^2h}{m+m'}=\frac{2gmh}{1+m'}$.

The nature of the soil to be traversed, and the number of piles to be driven in a given time, must be the determining motives for the selection of the pile-driving machinery to be adopted. For camp-sheeting the ringing engine will suffice; the Nasmyth's hammer is admirably adapted to soft, equable, soils; but the ordinary pile-engine worked by crabs is the best fitted for hard irregular soils.

PILES. [VEINS, DISEASES OF THE.]

PILGRIM is the name given to a person who travels for the purpose of visiting the shrines or tombs of holy men, or places which from any cause have come to be regarded as sacred; and the act itself is called Pilgrimage. The words pilgrim in English, *pilger* in German, *pellegrino* in Italian, *pélerin* in French, are all corruptions of the Latin "peregrinus," which means a stranger or foreigner. Pilgrimages to Jerusalem, Bethlehem, and other places which were the scenes of the Saviour's life and death, and which are included in the general name of the "Holy Land," began at an early period, probably about the time of Constantine. We are told by Eusebius and others that Helena, Constantine's mother, proceeded on a pilgrimage to Palestine, and built the church of the Holy Sepulchre. The practice became common about the end of the 4th century, and we find it noticed as such by the fathers of the church, Jerome, Augustine, and others. Gregory of Nyssa, in one of his epistles, reproves the indiscriminate custom of pilgrimages, especially by women, who, he observes, were particularly exposed during a long and toilsome journey through countries like Syria, notorious for licentiousness of manners. His opinions concerning pilgrimages are in accordance with those expressed by other fathers of the church. St. Augustine, St. Chrysostom, and St. Jerome, all agree as to the uselessness of such pilgrimages.

In the course of time, however, the practice of pilgrimage increased, and extended to other places besides Palestine. People resorted to the shrines of St. Peter and St. Paul at Rome, to that of St. Iago de Compostella in Spain, of St. Gregory of Tours in France, to the monastery of Einsiedlen in Switzerland, to our Lady of Loreto in Italy, to the tomb of Thomas à Becket at Canterbury, and to many other places.

The pilgrim's garb was a gray or brown gown, a broad-brimmed hat adorned with a palm leaf if going to the Holy Land, or a scallop shell if going to other places, with a long staff round at one end and pointed at the other; and his pouch was a hollowed gourd.

In the west, the celebration of the Jubilee perpetuated the custom of pilgrimages to Rome. The institution of the Roman Jubilee is due to Boniface VIII. At the beginning of the year 1300, a report was spread at Rome that all these who should visit the church of St. Peter that year would obtain a plenary indulgence, and that every centenary year enjoyed the same privilege. Pope Boniface searched the ancient records for the grounds of this report, and he interrogated a man 107 years old, who told him that in the year 1200 his father, a labouring man, had gone to Rome to get the indulgence, and had advised him, if he should live to the next centenary, to follow his example. Some other old men in France and Italy confirmed this tradition. After consulting the College of Cardinals, Boniface issued a bull, stating that "as according to the faithful report of the elders great indulgences are granted to those who visit the church of the prince of the Apostles every hundredth year, we confirm them, and grant plenary indulgence to all those who have confessed, and, being duly repentant, shall visit the churches of the Apostles during the present year, 1300, and every other centenary year after." This is the origin of the festival which was afterwards called jubilee. Fifty years later, Clement VI. reduced the period of its recurrence to half a century, and styled it jubilee in commemoration of the jubilee of the Jews, which was celebrated every forty-ninth or fiftieth year, when all slaves became free, and all lands returned to their original owners. (Leviticus, xxv. 10, *et seq.*) This jubilee began at Christmas, 1349, and it was attended by a prodigious concourse of people from all parts of Europe, it is said, more than a million at a time. Petrarca, who went to Rome on that occasion, speaks with wonder of the concourse of pilgrims. The crowd diminished during the heat of the summer, but increased again towards the fall of the year 1350, at which time the nobility, and especially the great ladies, from distant parts came. It appears that all these ladies came by the road of the March of Ancona, where Bernardino da Polenta, lord of Ravenna, one of those robber barons of the middle ages, and his men, lay in wait for them, and ravished some of them, and obliged the rest to pay ransom. The chronicler who relates this adds, that "had they remained at home, such mishaps would not have happened to them;" and that "indulgences and pilgrimages are not suited to young ladies." (P. Azar, *Chronica*, fol. 359.) Similar misfortunes are reported to have befallen those ladies who in former ages resorted to Palestine, when pilgrims were exposed to insults and even violence.

The period of the recurrence of the Jubilee has been altered several times; some popes reduced it to twenty-five years, in order that each generation should have the advantage of it. There are foundations at Rome for receiving and feeding the poorer class of pilgrims who resort there at jubilee time; one of these institutions or hospitals is called la Trinitá dei Pellegrini. The fashion of devotional pilgrimage however has very much decreased in our time; but yet there are annual "excursion" pilgrimages to the Holy Land from France, &c. The popes granted to several monasteries the privilege of holding jubilee, with the indulgences attached to it, every fifty years; among others to that of Canterbury. Concerning former pilgrimages, many notices are found in the ancient chroniclers, especially those of the Crusades. Chaucer, in his 'Canterbury Tales,' has given sketches of the pilgrimage to Thomas à Becket's shrine. Erasmus wrote a 'Pilgrimage to Walsingham and Canterbury,' republished in 1849, edited by J. G. Nichols. Henry Watson wrote 'Instructions for Pilgrims to the Holy Land.' Timberlake wrote the 'Travels of Two English Pilgrims to Jerusalem, Gaza,' &c.

The Mohammedans have also their pilgrimages. According to a precept of the Koran, every Mussulman who possibly can, ought once in his life to visit the tomb of the prophet at Mecca and the Holy Kaaba. [MOHAMMED, in BIOG. DIV.] The ceremonies performed by the pilgrims at Mecca are minutely described by Major Burton in his 'Pilgrimage to El Medinah and Mecca.' There are also sanctuaries for the Mohammedans of the sect of Ali at Mushed in Khorassan, and Koom in Irak Ajemi, which contains the tomb of Fatima, the sister of Iman Reza, which are visited yearly by numbers of Persian pilgrims.

The Hindus likewise have their places of pilgrimage, the most celebrated of which is that of Juggernaut or Jagathnatha, on the coast of Orissa in Coromandel, where extensive buildings are allotted for the idol and his priests. The statue of the idol is brought forth at certain periods, and mounted upon an enormous car sixty feet high, which is dragged along by the devout multitude amidst crowds of pilgrims, who resort thither from every part of Hindustan. The procession is attended by dancing girls and dissolute young men, who perform acts of obscenity, while, until the practice was discountenanced by the English authorities, fanatics threw themselves under the wheels of the car to be crushed to death. The whole scene, of which Buchanan, Laurie, and other writers give a full account, is a frightful compound of superstition, cruelty, and lust.

The Japanese are said to have their pilgrimages to the temples of Xinto or Xaca, of which accounts are given by Thunberg and other travellers.

PILING OF SHOT, an instance in which a process of pure mathematics, the summation of series, becomes of immediate application. Three shot, or spherical balls of equal size, placed together on the ground, will support a fourth, and four will support a fifth. Not more than four can be placed together so as to touch each other and support one more. Hence arise two distinct methods of piling shot, the triangular and the rectangular.

In a triangular pile the base is an equilateral triangle, with one shot at the vertex, two adjoining, three in the next row, and so on. The number of shot in the base (supposed to have n rows) is therefore $1+2+3+\dots+n$, or $\frac{1}{2}n(n+1)$. The number of interstices in which other shot can lie is $1+2+3+\dots+n-1$, or $\frac{1}{2}(n-1).n$. If such a pile be completed until one shot stands at the vertex, the pile will be n layers high, and counting from the top, the layers will severally contain $1, 3, 6, 10, \dots \frac{1}{2}n(n+1)$, of which the sum

$$\frac{n(n+1)(n+2)}{6}$$

is the number in a complete triangular pile.

Let there be a rectangular base, say of 16 by 11. The number of interstices is 15 by 10, and when the second layer is put on, the number of interstices is 14 by 9, and so on; whence the eleventh layer is a single row of 6. If a and $a+b$ be the numbers in the longer and shorter sides of the rectangular base, the number in the complete pile is

$$\frac{a(a+1)(2a+1+3b)}{6}$$

If the base be a square, $b=0$, and the number in the pile is

$$\frac{a(a+1)(2a+1)}{6}$$

PILLAR. [COLUMN.]

PILLORY. The pillory was a mode of punishment for crimes by a public exposure of the offender, used for many centuries in most of the countries of Europe under various names. In France it was called *pillorie*, and, in more recent times, *carcan*; and in Germany *pranger*. In England it existed before the Norman conquest, and was in frequent use in our criminal law from that period until it was finally abolished in the year 1837, by the statute 1 Vict., c. 23. In the laws of Canute (Wilkins's 'Anglo-Saxon Laws,' p. 11) it was called *healfange*, or, more correctly perhaps, *halsfang*, that is, catch-neck, a name derived, without doubt, from the form of the instrument used, and the mode in which the punishment was inflicted. Hence also the Latin name of the pillory, *collistrigium* (quasi collum stringens), is said to be taken. (Cowell's 'Interpreter,' ad. voc. 'Pillory.') The tumbrel, *trebuchetum*, an obscure punishment, which is said to be the same as the ducking or cucking stool, and was used for women, who were exempted, on account of their sex, from the pillory, is often spoken of in the ancient English laws in conjunction with the pillory. In early periods of English history, the right of having a pillory and tumbrel, and sometimes also *furcæ*, or gallows, within their jurisdiction, was claimed and insisted on as a beneficial franchise by lords of leets: in process of time this privilege was converted into a burden for the public use; and such persons were held to be bound to maintain a pillory and tumbrel as appurtenant to their criminal jurisdiction, on pain of forfeiture of their franchises. (Hawkins's 'Pleas of the Crown,' book ii., cap. 11, sec. 5.) In like manner the 'Droits de Carcan et de Pillori' are mentioned in ancient French customaries as belonging formerly to seigneurs haut-justiciers. (Vouglans, 'Loix Criminelles de France.')

The form of the pillory as used in England in the time of Henry VII., may be seen in a collection of prints published by the Society of Antiquaries. In modern times it was nothing more than a wooden frame or screen, raised several feet from the ground, and behind which the culprit stood, supported upon a platform, his head and arms being thrust through holes in the screen, so as to be exposed in front of it; and in this position he remained for a definite time, sometimes fixed by law, but usually assigned at the discretion of the judge who passed the sentence.

The pillory was intended "magis ad ludibrium et infamiam quam ad pœnam;" but serious injury, and, in some cases, loss of life, has occurred where the populace have been much excited against the offender. (Barrington's 'Antient Statutes.') On the other hand, where the unpopularity of the prosecution or other causes have occasioned a feeling in the public mind favourable to the offender, the execution has sometimes been a species of triumph.

In England the pillory was abolished by the statute above referred to; in France, the carcan was discontinued upon the revision of the Code Pénal in 1832; and in the numerous codes and schemes of codes which have appeared in the different states of Germany during recent years, punishments by public exposure of the person or otherwise tending generally to degrade the character have been omitted. ('Entwürfe für Würtemberg, Sachsen, Hannover, Baden,' &c.)

PILOT. In many maritime countries the name of pilot is applied to a constant officer in a ship, who has the charge of the helm and the general direction of the ship's course; and also to a person who undertakes the special charge of navigating ships in particular rivers, roads, or channels, or in entering and leaving ports, and who is entrusted with such charge independently of the captains or masters, in consequence of his peculiar acquaintance with the navigation within the limits to which his duty is restricted. In France large vessels usually carry several officers of the former kind, who are called *pilotes hauturiers*; the latter description of pilot is called *pilote côtier*, or *lamaneur*. The ancient laws of France contained provisions for the education and regulation of both these kinds of pilots (Merlin, 'Répertoire de Jurisprudence,' art. 'Lamaneur et Pilote;' Valin, 'Commentaire sur l'Ordonnance de la Maine du Moi d'Août,' 1681, tom. i., p. 483); but they are not mentioned in the Code de Commerce. In England the term is applied exclusively to officers of the latter description. By the laws of many maritime countries, taking a pilot to navigate a vessel on approaching port has been considered from early times to be obligatory on the master. Thus, by the laws of Wisbuy, which were promulgated in the 12th century, and were incorporated in the marine laws of most European countries, it was compulsory on the master to take a coast-pilot on board, though the merchant or master opposed it. ('Ordonnances de Wisbuy,' art. 44.) A similar provision is found in the 'Consolato del Mare.' (Boucher, 'Consulat de la Mer,' vol. ii.)

In this country, pilots are established at several ports for limited parts of the coast, who are appointed and regulated sometimes by acts of parliament, and sometimes by charters of incorporation; and in general the master of a ship engaged in foreign trade must put his ship under the charge of such a pilot, both in his outward and homeward voyage, within the limits of every such establishment. Pilotage in the Thames and Medway, and along the coast, from Orfordness to the Isle of Wight, excepting the jurisdiction of the Cinque Ports, has been for several centuries under the management of the corporation of the Trinity-house, and acts of parliament have been from time to time passed to regulate the Trinity-house and Cinque Port pilots. All these regulations were reconsidered by parliament in the year 1825, and the majority of them were consolidated in the statute 6 Geo. IV., c. 125, which contains also some general provisions respecting pilots in other parts of the kingdom. (Abbott 'On Shipping,' 1840.)

It was not till the passing of the Merchant Shipping Act, in August, 1854, that the present system of pilotage was organised. By it the existing powers for regulating pilotage were confirmed and arranged. Rules of pilotage, limits of districts, funds for superannuated pilots, the granting, renewing, and cancelling licence certificates, powers to make and amend by-laws—all these underwent revision: the Trinity-house being the source of authority in case of irregularities in the furnishing of returns, &c.; the whole being subject to the Board of Trade (*vide* 17 & 18 Vict., c. 104).

PIMARIC ACID. [TURPENTINE.]

PIMELIC ACID ($C_{14}H_{10}O_6 2HO$). A white crystalline acid, obtained by the action of nitric acid upon oleic acid, bees'-wax, spermaceti, linseed oil, and other fatty bodies. It is a bibasic acid, and its neutral salts have the formula $C_{14}H_{10}O_6 2,MO$.

PIMENTA, or PIMENTO, allspice, the produce of *Eugenia Pimenta*, a tree native of the West Indies, but cultivated almost exclusively in Jamaica, thence called Jamaica pepper. The unripe two-seeded berries, which are about the size of a pea, are dried by frequent turning in the sun, by which their colour is changed from green to brown or grayish-brown. Externally they are of a dull appearance, somewhat rough, crowned with the remains of the calyx, and frequently furnished with a little stalk. The shell is very brittle, about the thickness of a card, and encloses two seeds, which are roundish, dark brown, and somewhat shining; and having a weak aromatic taste. The shell possesses an agreeable clove-like taste and smell. Two kinds are met with in commerce, English and Spanish, of which the former is the better.

Pimento berries are said to be adulterated with the berries or seeds of the Cocculus Indicus; these are larger, about the size of bay berries, extremely bitter, and, in large quantity, poisonous. This adulteration is scarcely credible, for the latter come from the East Indies, are dearer, and could only be successfully passed off when mixed with the powdered berries of pimento. The fraud may be detected by making an infusion, which, if pure, is not disturbed by tincture of galls or acetate of lime, which cause a precipitate when cocculus berries are present.

The shell appears to be the most efficient part, and to contain more of the active principles.

Bonastre obtained from the shells 10 per cent. of a heavy volatile oil, 8 per cent. of a green fat oil, an extractive containing tannin, resin, gum, and sugar; also a principle similar to caryophyllin.

By distillation an oil is procured which resembles oil of cloves, and which conducts itself in the same way towards alkalies. It is a mixture of a light and heavy oil.

As an aromatic stimulant, pimento stands intermediate between pepper and cloves, for the last of which, on account of its greater cheapness, it may often be substituted.

It is useful in dyspepsia dependent upon atony of the stomach, and in diarrhœa dependent upon a similar cause.

PIN MANUFACTURE. It is not known at what time pins made of metal of the present form were first manufactured in this country, but it must have been some time previous to 1543. In this year a statute was passed (35 Henry VIII., c. 6), intituled "An Acte for the True Making of Pynnes," in which, after stating that much deceit had been practised in the making of pins, it was enacted that in future none should be sold but such as were well pointed and had the heads firmly soldered on to the stems, and further that the price charged should not be more than six shillings and eight pence a thousand. No mention is made of them in any previous statute, with the exception of an act of Richard III., which prohibited their importation from abroad; but the pins there alluded to were much larger than those now in use, and were made of box-wood, bone, or silver.

Pins of English manufacture being in great repute abroad, the foreign trade is very considerable. The number actually made in this country daily was estimated thirty years ago at fifteen millions; but it must now be far greater, although there exist no means of determining it. By hand labour ten persons can produce a pound, or about 5500 pins of medium size, in rather less than eight hours: each person taking up the work as soon as the operation preceding that which he or she has to perform is completed, and each being employed about a tenth part of the eight hours. These calculations, relating to the division of labour, are taken from Babbage's 'Essay on the General Principles which regulate the application of Machinery,' in the portion of the 'Encyclopædia Metropolitana,' comprising Manufactures and Machinery; they are valuable in relation to the division of labour, but the statistics or quantities are no longer strictly applicable to the manufacture under notice.

The first thing to be done, in the pin-manufacture, is to reduce a quantity of brass wire to the requisite size. This, though properly speaking a preliminary operation, is generally done in the pin-factory, as the wire is received of larger diameter than necessary. It is performed in the usual manner of wire-drawing. The wire is then made up into coils of six inches diameter; and any dirt or crust which may be attached to the surface is got rid of by first soaking the coils in a diluted solution of sulphuric acid and water, and then beating them on stones. The next process is to straighten the wire. Two short lines, parallel and very close to each other, are drawn at one end of a board or table, and seven or nine pins are driven into the wood, at a short distance apart, alternately in the two lines. The end of the wire is placed between these two rows of pins and is thus held in a zig-zag position: it is then drawn between the pins to the other end of the table, and a length of about twenty feet is cut off. This process is repeated until all the wire is straightened and cut into similar pieces. A number of these lengths are then taken together, and by means of a powerful pair of shears, worked by the foot, they are cut up into shorter pieces, each a little longer than six pins. These latter pieces are then pointed at each end. The pointer sits in front of a small machine, which has two steel wheels or mills turning rapidly. These wheels are usually about six inches in diameter, and their rims or cutting surfaces are about three inches broad. The rims are cut somewhat after the manner of a file: one coarse, for the rough formation of the points, and the other fine, for finishing them. Several of the pieces of prepared wire are taken in the hand, and by a dexterous movement of the thumb and fore-finger are kept continually presenting a different face to the mill, against which they are pressed. The points are then finished off by being applied in the same manner to the fine mill. After both ends of the pieces have been pointed, one pin's length is cut off from each end, when they are repointed; and so on until each length is converted into six pointed pieces. The stems of the pins are then complete. The next step is to form the head, which is effected by a piece of wire called the mould, the same size is that used for the stems, being attached to a small axis or lathe. At the end of the wire nearest the axis is a hole, in which is placed the end of a smaller wire, which is to form the heading. While the mould wire is turned round by one hand, the head wire is guided by the other, until it is wound in a spiral coil along the entire length of the former. It is then cut off close to the hold where it was commenced, and the coil taken off the mould. When a quantity of these coils are prepared, a workman takes a dozen or more of them at a time in his left hand, while with a pair of shears in his right he cuts them up into pieces of two turns or spirals each. To prevent them from flying off from the shears when separated, the fore-finger of the left hand is applied to the tip of the coil, and the end thus cut off is caught in a bowl placed beneath it. In some factories this is performed by a chisel and gage, instead of the shears, a mode which has the advantage of requiring less dexterity. The heads, when cut off, are annealed by being made hot and then thrown into water. When annealed, they are ready to be fixed on the stems. In order to do this, the operator is provided with a small steel die, containing a hollow the exact shape of half the head. Above this die, and attached to a lever, is the corresponding die for the other half of the head, which, when at rest, remains suspended about two inches above the lower one. The workman takes one of the stems between his fingers, and dipping the pointed end into a bowl containing a number of the heads, catches one upon it and slides it to the other end; he then places it in the lower die, and, moving a treadle, brings down the upper one four or five times upon the head, which fastens it upon the stem, and also gives it the required figure. There is a small channel leading from the outside to the centre of the dies, to allow room for the stem. The pins are now finished as regards shape, and it only remains to tin or whiten them. They are boiled in a pickle, either a solution of sulphuric acid or tartar, to remove any dirt or grease, and also to produce a slight roughness upon their surfaces, which facilitates the adhesion of the tin. After being boiled for half an hour, they are washed, and then placed in a copper vessel with a quantity of grain tin and a solution of tartar; in about two hours and a half they are taken out, and after being separated from the undissolved tin by sifting, are again washed. They are then dried by being well shaken in a bag with a quantity of bran, which is afterwards separated by shaking them up and down in open wooden trays, when the bran flies off and leaves the pins perfectly dry and clean.

Papering the pins for sale is one of the slowest operations in the manufacture. When the pins are separated from the bran, as just described, they are thrown into bowls, with their points in all directions; but before papering it is necessary to arrange them all the same way. This is done by laying a number of them upon a sort of comb, between the teeth of which they are caught by the head; they are then placed upon a piece of metal, with as many grooves as there are pins required in a row, and held there by another piece of metal being placed upon them. These pieces of metal are not quite so broad as the pins are long, so that their points project beyond the edge of the metal. The paper is folded into the required shape, and pressed against the points of the pins, which are then relieved from the holder; and the next row is arranged in like manner.

Of these operations, drawing the wire, cutting it into lengths, cutting the heads from the coils, and tinning, are performed by men; the rest by the women and children.

The above description relates to the manufacture of pins by hand. It must now be stated, however, that most of the operations have gradually been brought within the scope of machinery. One of the earliest pin machines was that of Mr. Rundy. This machine fixed on the heads in the old manner, but more firmly. Each head was fastened by one blow, and several pins were operated on at the same time. Since that time several other machines have been invented for forming the head out of the stem of the pin itself, by pressing a small part of the end of the stem into a hollow die. A large proportion of the pins now manufactured are made in this way, and are much superior to those made in the old fashion. One objection however has been urged against them. It is stated that to form the head in this manner by pressure, the wire requires to be very soft, and consequently the pins will easily bend; but this evil has gradually been somewhat lessened. In Wright's pin-making machine, motion is given either by manual power or by machinery to a strong axis working in collars. This main axis carries several cams or excentric wheels which put forward at each revolution as many levers or slides at right angles to the main axis. These levers return to their former situation as soon as the cam ceases to operate by means of a strong spiral spring attached to each; at the other ends of these slides the different operations are performed. A coil of brass-wire of the requisite size is placed upon a reel and spindle, and the end is drawn through a set of zig-zag pins as before described for straightening the wire, and placed between the teeth of a strong pair of pincers. This is all that is necessary to be done before setting the machinery in motion. The first slide then moving forward shuts the pincers upon the wire and instantly carries it forward into a nipping-gauge which closes and cuts off sufficient for one pin. This length can be regulated by the adjustment of a small screw attached to the first slide. The piece thus cut off is carried by an ingenious little adaptation called a carrier to the next operating slide. These carriers are four in number, mounted on a bar at right angles to the working slides, and parallel to the main axis; this bar has a motion given to it in the direction of its length, and moves once for every pin-length of wire cut off by the gauge before mentioned. The carriers themselves are made somewhat in the manner of a pair of pliers, the under chap being kept up to the other by a spring. The juncture of these chaps is exactly opposite to the pin, which is forced between the chaps and carried to the next operation. The piece of wire is deposited by the first carrier in the centre of a chuck attached to a small mandril, which by a moveable lever clutches the pin; the instant this is done, the frame which supports the mandril is tilted so as to bring the point of the pin down upon a revolving steel mill just below it; a lever or finger then presses the end of the wire upon the mill, and at the same instant the mandril carrying the pin is set in motion. The wire is thus ground to a point; the mandril frame then rises, the mandril itself is brought to rest, the pin released, and conveyed by the second carrier to a finer mill, where the point is completed by exactly the same process as the preceding. It is then taken by the third carrier to the first heading die, where the body of the pin is firmly held while a steel punch advances against the end of the wire, and forcing it into a hollow in the die, partially forms the head. The last carrier then takes the pin, and placing it in another die, the head is completed by another punch; a small forked lever then draws the finished pin from the die, and drops it into a receptacle below. The pins are then tinned in the manner previously described. These operations are carried on by the machine simultaneously, and each occupies the same time; five pins being constantly under operation in the different stages; the machine will produce fifty or sixty pins per minute, and only requires the attendance of one person.

The patent method, just adverted to, was devised by an American of Massachusetts, but was first tried in England. A large factory was set up for the purpose at Lambeth, stocked with sixty of the pin-making machines. A difficulty at first arose in heading the pins; and a new machine was invented for this purpose. A lengthened period of ill-success brought on the ruin of the company by whom the enterprise was conducted. Mr. Taylor, one of the sufferers by the scheme, bought the machines at a low price, took them down to Stroud in Gloucestershire, made several improvements, procured the assistance of capitalists, and established a solid-headed pin manufactory. This led to the establishment of others; and Stroud is now one of the head-quarters of the trade.

America was supplied with pins from England until 1812; when the war between the two countries checked the import, and set the inventors to work. Manufactories were established at New York and elsewhere; but when the war ended, the United States were suddenly glutted with English pins at a price so low as to ruin these enterprises. Gradually, companies were formed (as is usual in the United States) to conduct the manufacture by new machines; and at the present time, some of these companies conduct the operations on a very large scale, making eight or ten tons of pins per week each. The Americans have been successful in inventing machines whereby the papering of pins can be conducted with great expedition.

PIN-MONEY. Gifts by a husband to his wife for the purchase of apparel, ornaments for her person, or for her private expenditure, are called pin-money; and such gifts may either be made during marriage, or, what is the more usual case, a sum of money for that purpose may be secured by settlement, or by articles executed before marriage. It is only money secured before marriage that is properly called pin-money; for a gift of money to the wife after marriage is liable to the husband's debts; but a provision for pin-money is not so liable, and the wife is entitled in all cases to such money, and to her savings out of it, and things bought with it.

Several of the questions upon pin-money have arisen after the husband's death when arrears have been claimed by the wife; and it is the general rule that she can only claim arrears of one year's pin-money if she has been supported by the husband with necessaries during the time that such arrears have accumulated, it being presumed that she has waved her claim to pin-money; but she may by evidence rebut such presumption.

If the husband leave a legacy to the wife equal to the arrears of pin-money or more, such legacy, according to the general rule as to the satisfaction of debts by the giving of legacies, will be considered as a payment of the arrears due at the time when the will was made. If a wife elope and live apart from her husband, either in a state of adultery or not, she does not thereby forfeit her right to her pin-money, and she may recover it.

PINE-APPLE, the fruit of the *Ananassa sativa*, Lindl., a tropical plant, indigenous to South America and some of the West India Islands. It has become so perfectly naturalised in many parts of the hot regions of Asia and Africa, that it has been thought to be likewise a native of those countries. It was, however, first introduced into Europe from South America, and, as it is recorded by M. Le Cour of Leyden, about the middle of the 17th century: from Holland it was brought to this country in 1690, by the Earl of Portland, according to the Sloanean MSS. in the British Museum. There is a painting, formerly in the collection of Horace Walpole, in which Charles II. is represented as being presented with the *first* pine-apple by Rose, his gardener; but there are some doubts whether that fruit was grown in England or obtained from Holland. It may, however, be fairly concluded that pine-apples were exceedingly rare in this country, even at the tables of the nobility, in the beginning of the last century; for in 1716, Lady Mary Wortley Montagu remarks that pine-apples were on the electoral table at Hanover when she was there in that year, on her journey to Constantinople; and she states that she had never previously seen that species of fruit. ('Letters of Lady M. W. Montagu.') Since that period the cultivation of the pine-apple has been prosecuted with perseverance in Britain, but frequently the results have been very disproportionate to the expense incurred. At the present day the pine-apple in England is so abundantly produced, that although expensive, it is very common. Its delicious flavour, and the noble appearance which a well-grown fruit exhibits, render the cultivation of it a special object of horticultural enterprise and skill.

As notwithstanding the many treatises that have been written on the subject, failures in the production of fine fruit continue to occur, it seems desirable to point out in what the mismanagement of a gardener is most likely to consist, and how he may apply the directions to be found in books of gardening with least chance of failure.

It has been already stated that this plant is an inhabitant of the tropics, and, it may be added, near the level of the sea. The latter circumstance it is necessary to remark, because if it were a mountain plant, even though tropical, it might be natural for it to endure a comparatively low degree of temperature. But according to Beyrich ('Gardeners' Magazine,' iii. 442), "the pine-apple in its wild state is found near the sea-shore, the sand accumulated there in downs serving for its growth, as well as for that of most of the species of the same family. The place where the best pine-apples are cultivated is of a similar nature. In the sandy plains of Praya Velha and Praya Grande, formed by the receding of the sea, and in which no other plant will thrive, are the spots where the pine-apple grows best." The temperature at the level of the sea at or near the equator varies but little throughout the year; for instance, the mean temperature of the warmest month at Cumana, 10° 27′ N. lat., is, according to Humboldt, 84·38°, and that of the coldest 79·16°. At Havanna, on the skirt of the tropics, the mean of the warmest month is 83·84°; that of the coldest 69·98°. At Vera Cruz the mean temperatures of the warmest and coldest months are respectively 81·86° and 71·06°.

In conformity with the above, and also from the results of experience, it may be stated that the artificial temperature of the atmosphere in which the pine-apple is intended to be grown should have a mean of about 80°; or a minimum not lower than 70° at any time of the year, and a maximum not higher than 90°. When, from the shortness of our days in winter, there is a deficiency of light, and when forcing the plant in its absence would produce only imperfectly formed tissue, 70° will be proper. In summer 80° to 85°, or in the case of fruiting plants, from that to 90° will not be too much. The maximum by sun-heat may extend higher, but 100° should be its limit.

With regard to bottom-heat, it should be in imitation of the heat of the tropical soil; and this varies even less than the temperature of a tropical atmosphere. The mean temperature of the earth is generally supposed to be somewhat higher than the mean of the atmosphere, owing to the greater capacity of the soil for retaining caloric. The discrepancy, however, cannot be great; and if the mean atmospheric temperature at the equator be from 80° to 84°, as has been ascertained from numerous observations, the temperature of the soil, it may be presumed, will not average lower; nor will it be many degrees higher where moisture sufficient for vegetation exists, as is generally the case in islands; although on continents it becomes so great as to reduce the soil to a desert. The temperature of the earth a foot below the surface, in New Granada, is 85° during summer, according to a correspondent of Mr. Hay ('Gard. Mag.'); and this degree of heat will be found a very good medium for the roots of the pine-apple. Bottom-heat then should never be allowed to fall below 75°, nor rise higher than 90°.

Pine-apples can be raised from seeds, but in England this is rarely done except for the purpose of procuring varieties. They are propagated usually from suckers. Formerly the crowns were used, but the suckers are found to be more early productive. The soil in which they are planted requires to be rich. A fresh yellow loam, strong, but by no means of a binding nature, with which is mixed a quantity of cow-dung, will answer very well. The pots require to be well-drained, and over the drainage some pieces of turf may be placed. Manure-water, made by steeping sheep's-dung or cow-dung, is occasionally applied, care being taken that it be properly diluted. If the plants are found not to be thriving, they may be shifted, without hesitation, at any period of their growth.

It is very important that a perfect drainage be at all times maintained. When pots are plunged in tan, the worms are apt to close the holes in the bottom of the pots by their excretions; or a stoppage may occur in consequence of the pressure of the pot upon the tan when it wastes and becomes capable of being rendered compact. From whatever cause the defect proceeds, a good preventive may be easily effected by simply plunging an empty pot, with its *mouth downwards*, and on this placing the bottom of that containing the plant, closing the tan round the sides of the latter in the usual way. If at any time the tan should become too hot, it may be partially removed from the sides of the pot.

Moisture is essential for the growth of the pine-apple. The condition of the soil in the pots will of course indicate whether water should be applied or withheld. But in summer the atmosphere should be kept moist by syringing, particularly before shutting up at night. No water should on any account be used of a temperature many degrees lower than that of the soil in the pots where the plants are growing; it should not, in short, be applied lower than 75°, and 80° will prove a good medium. When the fruit is ripening off, moisture of course should be withheld; and in damp cloudy weather in winter, when it is an object to restrain rather than promote growth, they should be kept rather dry than otherwise. Moisture will not prove injurious when it is accompanied by a sufficiently high temperature and a due share of light. The mode of heating by means of hot-water pipes is undoubtedly the best for pine-stoves; and steam from the boiler should be at command, so that it may be introduced to the interior of the house as occasion requires.

Pine-apples may be grown under various modes of treatment. Instead of being confined in pots, they are sometimes planted in a bed of soil. This has been found to answer very well where good drainage was secured, and where a proper degree of bottom-heat could be applied. They have also been grown in pots placed on shelves or on sand; this mode, however, has not proved fully successful, for the roots are subjected to vicissitudes consequent not only upon the variations in the temperature of the atmosphere of the house, but also its hygrometrical conditions.

A principal cause of failure in the cultivation of the pine-apple appears to have arisen from the idea that the plants will bear a much lower degree of temperature than that above pointed out as being natural to them. They will *apparently* do so; but although the plants may continue to have a healthy appearance, yet experience proves that their vital energy is interfered with, and their powers of organisation diminished, as is continually indicated by the fruit stem being sent up with only a few imperfect pips. The stagnation of water about the roots from defect of drainage, too much heat and moisture, or too much heat and dryness, or checking the plants by cold in order to bring them to a fruiting condition, instead of forwarding them naturally to that state, are other sources of failure on the part of cultivators. With regard to the last, the only method that ought to be taken to bring on the time of fruiting is to inspissate the sap, and to augment the amount of secretions by gradually withholding moisture and increasing the temperature, at the same time admitting a little more air than usual; and after this, by the sudden application of a brisk temperature with more moisture.

To richly manured soil the large size of the pine-apples produced in England may be attributed; and to the means that cultivation under glass affords of progressively inspissating the juices towards the period of ripening, may be ascribed the superiority of the fruit to that produced in countries where the plants are indigenous, as alluded to under Ananassa sativa, in Nat. Hist. Div.

Pine-apples are now cultivated to a large extent in the Bahama Islands for the English market.

PINE APPLE, *Essence of.* [Butyric Acid.]

PINIC ACID. [Turpentine.]

PINIPICRIN ($C_{44}H_{36}O_{22}$?). An amorphous bitter organic substance contained in the leaves of the *Pinus sylvestris*. It is soluble in water and in a mixture of alcohol and ether.

PINITANNIC ACID. [Tannic Acids.]

PINITE ($C_{12}H_{12}O_{10}$). A saccharine substance produced by the action of fire upon the trunk of the *Pinus Lambertiana*, in California. It is eaten by the Indians. It does not ferment.

PINK. The flower so called (*Dianthus plumarius*) belongs to the genus Dianthus, to which also belong the carnation (*Dianthus caryophyllus*), the sweet-william (*Dianthus barbatus*), and others, and the cultivation of all of them is similar. Although some of the species are indigenous to Great Britain, by far the greatest number are natives of the southern parts of Europe; abounding in Germany, Switzerland, Italy, and along the shores of the Mediterranean, Black, and Caspian Seas, inhabiting rocks, mountains, and dry, warm, stony places most frequently, although occasionally living in sandy and damper places.

It is therefore obvious that the gardener must pay special attention to this peculiarity, and guard by every means in his power against the access of wet, unless when the plants are in a state of free growth. In the winter, when they are at rest, they bear moisture very impatiently. It is therefore either upon rockwork or in pots housed in winter that the species of Dianthus are best preserved. The soil in which they are planted should consist of equal quantities of good fresh loam and vegetable mould, to which may be added a little horse dung and sand, the whole to be mixed well, and allowed to remain for a season before being used.

All the species may be propagated either by seeds or by layering or piping. Both operations should be performed about the end of May or beginning of June. Layering is decidedly the surest method, as the young shoot derives support from the parent plant until it has protruded rootlets of its own for nourishment. In this operation gardeners generally practise a method technically called tongueing, which is simply making a slit with a knife, from a little below the joint, up through its centre, and then carefully pegging the young shoot down as in the common way. Pipings are a sort of cuttings, and will root freely in a melon or cucumber frame, which can often conveniently be applied to this purpose in the end of the season; but as artificial heat is not essential to success, those who have not this convenience may succeed very well with a small hand-glass.

If the pipings are not in a shaded situation, it is necessary to shade them when the sun's rays are powerful; because the rootlets are for some time insufficient to supply the stem with fluid enough to counteract the effects of evaporation. It is the want of due attention to this which causes the result of propagating the Dianthus by pipings to be considered uncertain: if shade and moisture are supplied for a sufficiently long time, there is little risk of the pipings not forming young plants.

When the young plants are rooted they should be transplanted into beds, about 6 inches apart; the soil of the bed being a rich loam and not less than a foot in depth, and well drained. As they begin to bloom remove all but two or three of the flower-buds, and the flower-stems should be supported by being tied loosely to sticks.

PINK SALT ($NH_4Cl, SnCl_2$). A double chloride of tin and ammonium, used as a mordant by dyers.

PINK SAUCERS. [Carthamin.]

PINT, the half of a quart, and the eighth part of a Gallon, which is the standard measure connected with the pint.

PINUS BALSAMEA. [Balsam, *Balsam of Canada.*]

PIONEERS. There are thirteen picked men (artisans) in each regiment of infantry who act as pioneers: these carry no muskets, but a sword with a saw back which acts as a weapon, and also as a tool. Besides which a regular complement of tools, such as picks, shovels, felling axes, saws, crowbars, is divided amongst and carried by the men, slung on their shoulders, or strapped to their backs. Pioneers are employed in the field in removing obstacles, and on the line of march in rendering posts defensible, doing repairs in camp, or directing working parties, &c.

PIPE (measure), a name given to two hogsheads of the old wine measure; two hogsheads of ale or beer were called a butt.

PIPE. A column of air contained in a tube and maintained in a state of vibration yields a musical sound, depending upon its length and (slightly) upon the state of the atmosphere. Our object in the present article is to give such an account of the theory of a musical pipe as may, with the articles Acoustics, Cord, Harmonics, Scale, Temperament, &c., complete the statement of the leading principles of sound and the doctrines of music.

In this subject a distinct line should be drawn between those circumstances which are of easy and difficult explanation: for example, to a person who thoroughly understands the composition of waves moving in opposite directions [Acoustics], it is not difficult to point out what the state of a pipe must be when in musical vibration; but to explain how the action of a current of air, as in the common flute, or the joint action of the air and a reed, as in the clarionet or reed-stops of an organ, produces and maintains this state of vibration, is quite another thing.

We shall first consider the pipe in a state of continued sonorous vibration (no matter how produced), yielding the lowest note which it will give: let it be a simple pipe open at both ends, and let it be sounding, say the c of the treble clef, which note requires 258 double vibrations per second. If we now remember that the air at the two extremities is in communication with the outer air, we see that no condensation or rarefaction can take place at those extremities, or only very small ones compared with those which take place in the interior of the tube. To get approximately at the conditions of vibration, let us suppose that no condensation or rarefaction takes place at the extremities. We then see [ACOUSTICS] that the state of the pipe, its two extremities never being condensed or rarefied, is as it would be if two waves of sound were travelling in opposite directions, every particle of the interior being affected by the joint condensations and velocities of both. Moreover, the distance between two uncondensed particles is always the whole length of the wave of condensation or that of rarefaction, or a multiple of this length; that is, the pipe must be either the half-length of a double wave or a multiple of this half-length. When the pipe sounds the lowest note, it must give the longest wave; that is, the length of the pipe must be that of the simple wave of condensation or rarefaction. Hence, the lowest note which a pipe can yield, which is called its *fundamental* note, is that belonging to a double wave of sound which is double of its length. Each double wave answers to a complete or double vibration of a string.

To compare this result with practice, let us suppose sound to travel at the rate of 1125 feet per second (temperature 62° Fahr.). The note c having 258 double vibrations per second, this 1125 feet must contain 258 double waves, or each double wave must be 4·36 feet. The single wave then is 2·18 feet, or 2 feet 2 inches and ·16 of an inch, which is the *theoretical* length of the pipe. Now the organ-builders say 2 feet [ORGAN, CONSTRUCTION OF], but this of course is a rough description, since the French organ-builders also say 2 feet (according to Biot), and the French foot is longer than the English. Further on in the article referred to we see 2 feet 2 inches given as the length of this c in an open pipe (the dulciana), and 1 foot 1 inch in a stopped pipe (the stopped diapason), which, as we shall presently see, ought to be half as long as an open pipe. The common flute, when everything is stopped, gives this same c, and the length from the embouchure (or mouth hole) to the end of the instrument is a little more than 2 feet, but certainly never 2 feet 2 inches. It must be remembered however that this instrument is made up of the flute (so called) and the player, whose lips, when they come over the embouchure, confine the air, and are equivalent to a slight lengthening of the pipe. It is not the manner of blowing which does this, but the approach of the lips, as may be thus shown. Take a common flute, and without holding it to the lips, strike the uppermost hole with the finger; a faint sound will be heard. Now approach the lips to the embouchure, but without blowing, and then strike the same hole with the finger; another faint sound will be heard, decidedly flatter than the former. It is well known to those who play on this instrument (to those who play in tune at least) that drawing the lips back, so as not so much to confine the air contiguous to the embouchure, sharpens the tone, and what some persons call *humouring* the instrument means continual alteration of the position of the lips, so as to shorten or lengthen the pipe by turns, according to the note to be sounded. It is also well known to players that this humouring can be carried to a much greater extent with the high notes than with the low notes; but so little were the practical musicians in connection with the theoretical in the time of Daniel Bernoulli (who first gave the mathematical theory of this subject), that this simple fact was only discovered by him from a new and somewhat complicated experiment.

In the preceding theory all the parts of any section of the pipe perpendicular to its axis are supposed to vibrate in the same manner. This cannot be the case in the common flute or in the organ-pipe, in which the cause of condensation is supplied at the side; and in fact all experiments in which the cause of undulation has been equally applied over all the parts of a section perpendicular to the axis, have agreed in the result that the time of vibration is wholly independent of the diameter of the tube: while those in which the same was not equally applied give the result that the greater the diameter the lower is the tone. Moreover, when an orifice is made in the side of a pipe, as in the flute, it is not equivalent to the formation of a new pipe terminating at that orifice, though the results are somewhat resembling. Any note between the fundamental note and its octave may be obtained by an orifice of one size or another made at or near the middle of a pipe.

We have seen that we may suppose the extremities of the open pipe to contain between them 2, 3, &c., half-waves, which the whole pipe being one half-wave in length, will give the HARMONICS of the fundamental note. This subject is sufficiently treated in the article cited.

Various instruments yield different harmonics more or less readily; the general rule being that the more violent the agitation which produces the sound, the larger the number of half-waves formed in the tube, and the higher the harmonic: also that a certain diameter, the larger the greater the length of the tube, is necessary to the production of the fundamental note. Thus, if an organ-pipe be too small in the bore, it will yield the octave of the fundamental note; or if the latter, only with great attention to the *voicing*, or adjustment of the orifice through which the wind enters. If the bore of a flute be too narrow (which we imagine to be the case in modern instruments), the lower notes will be difficult to obtain. And the various harmonics are produced with very different degrees of facility; a circumstance of which the theory can give no account. Thus, players on the trumpet find it exceedingly difficult to produce that tone which divides the instrument into seven parts, or the flat seventh in the third octave above the fundamental note; while in the flute there is no moderately skilful player who cannot produce it. It is to be observed however that all pipes of the trumpet class are of tapering diameter; and though they agree in all material points with the theory of cylindrical and prismatic pipes, it is not remarkable, in the present state of the mathematical analysis of this subject, that they should present circumstances difficult of explanation.

It will be obvious, from the considerations in ACOUSTICS, that when the extremities of the pipe contain between them n half-waves, there will be $n+1$ points (the orifices included) at which the velocities are always greater than elsewhere, and no condensations or rarefactions; and n points (in the middle of the subdivisions), at which the condensations or rarefactions are always greater than elsewhere, and which are always at rest or nearly so. These immoveable points are called *nodes* of vibration; and there is one of them in the middle of the tube only when the number of half-waves in the pipe is odd.

Let us consider the case of a pipe with one end closed. It is obvious now that the open extremity is a point of no condensation, while the closed extremity must be a node, or point of no velocity. Hence the tube must be the half of an odd number of simple waves in length, twice the tube must be an odd number of simple waves, and four times the tube an odd number of double waves in length. Hence the fundamental note belongs to a double wave of four times the length of the tube; so that the fundamental note of a pipe closed at one end is an octave lower than that of the same pipe open at both ends. It is the same thing to say that a pipe of half the length of an open pipe, closed at one end, gives the same note as the open pipe. This is the reason why the pipes of the stopped diapason stop of an organ are halves of the lengths of those of the open diapason.

Again, since the double length of the pipe is an odd number of simple waves, the harmonics which the pipe can yield are not the complete set yielded by the open pipe of double the length, but every other one, beginning from the fundamental note. The number of vibrations per second being 1, those of the harmonics producible by the pipe closed at one end are 3, 5, 7, &c. We will leave the pipe closed at both ends (a matter of no practical concern, since its sound could not be heard) to the student; the result he should arrive at by the preceding considerations, is that it is in all respects analogous to the vibrating CORD fixed at both ends. But he must not infer, by a reversed analogy, that the vibrations of an elastic body fixed at one end (as the spring of a tuning-fork) answer to those of a pipe closed at one end, since their law is very different.

It is usual first to give the theory of a closed pipe, and then to suppose the open pipe made of two closed pipes, with their closed ends together, and their closing diaphragms removed. The opposition of the vibrating movements will then keep the particles in the middle at rest. This is a sufficient explanation of those modes of vibration of the open pipe in which there is a node in the middle.

We now come to the explanation of the manner in which the sonorous vibration of a pipe is maintained. If we suppose a vibrating body placed at the orifice, it is found that if the vibrations of the body be equal or nearly equal to those of the fundamental note of the tube in the preceding theory, or one of its harmonics, the sound of the vibrating body is reinforced by the tube. A slight alteration of the tube, though it may sharpen or flatten the note, does not by any means produce such a difference as would be caused by the same alteration, if the sound were caused by the tube alone. We do not intend to go into this subject; the reader may find it discussed, both mathematically and experimentally, in a paper by Mr. Hopkins, published in the fifth volume of the 'Transactions of the Cambridge Philosophical Society.'

When the sound is caused by a current of air, as in the common flute or simple organ pipe, a tolerably satisfactory explanation of the phenomena has been given in the case of the pipe closed at one end (to which writers have confined themselves); but none whatever in that of the pipe which is open at both ends. In the former case, as in a reed of the Pan's pipe, a current of air is directed laterally over the mouth of the pipe, with a slight obliquity of direction. A condensation is therefore produced in the tube, which travels to the closed end, and is there reflected; so that by the time the condensation has travelled over twice the length of the tube (down and back again), the whole condensation, such as it was when it began, is doubled. Hence the air in the tube has now become more powerful than the external stream, and the condensed portion begins to be discharged. This continues until not only the whole of the condensation is discharged, but also until all the velocity of the issuing particles has been destroyed; and this is not done until the effect of that velocity has produced a rarefaction in the tube. The effect of the condensation is destroyed in the same time as that in which it was produced; and hence the complete undulation belonging to the whole length of the closed tube is four times the length of the tube. Imperfect as the preceding explanation is, we know of no way of applying even so much to the open tube.

It is also to be noted that the whole of the preceding theory is but an approximation. The extremities of the open tube are not points of absolute non-condensation and non-rarefaction, but points at which the condensations and rarefactions are least and small. Similarly the nodes are not points in which the air is absolutely at rest, but points at which the motion is least. The extensions of this theory, however, important as they are in a physical point of view, are not essential to that fundamental explanation of the musical phenomena of a pipe, to which we have expressed our intention of confining ourselves in the present article.

PIPE, a circular or square artificial channel for the conveyance of watery fluids, either under pressure, or flowing freely, or for the passage of æriform fluids, or of sound. According to the almost endless varieties of uses to which pipes may be converted, and to the positions in which they may be placed, the materials of which they are formed may be modified in an equally varied manner. A few of the more prominent uses, and of the more generally adopted materials, are therefore all that it will be possible here to allude to, under the general name of *pipes*.

For the purpose of removing rain-water from buildings the ancients, and even occasionally the moderns also, have resorted to the use of earthenware pipes of ordinary clay baked in kilns, but of late years lead, zinc, or iron pipes have been used in preference either to the earthen, or the stoneware pipes. Copper pipes are commonly used for the ascending pipes from force pumps; but the distribution of water horizontally is almost always effected through cast or wrought iron, lead, or tin pipes. Gas is distributed through cast iron mains, wrought iron service-pipes, or through small pipes of tin, or of mixed metal with a tin base. The foul waters from modern houses are removed through glazed stoneware drains, whilst land drainage waters are removed by means of red earthenware pipes. Until within a very few years the whole of the water supply of our towns was carried through elm pipes; and at the present day wood is still used for conveying water in agricultural districts, whilst that material is considered to be the most fitted for the conveyance of such fluids as tan liquor, or the bilge waters of ships. Indian rubber and gutta percha pipes are sometimes used for garden and irrigation purposes; and leather pipes are almost universally used for fire engines, or for moveable pumps, of any kind.

Smoke, hot air, and hot water are conducted through pipes or channels formed, as the case may require, of ordinary bricks; of moulded bricks, of glazed brick, or stoneware pipes; or of cast or wrought iron, or of copper, zinc, lead, or tin; and in the construction of boiler furnaces, of drawn brass. Sound is conveyed through metal pipes, or through Indian rubber, or gutta percha tubes.

The stoneware and cast iron pipes certainly are the most durable under ground; but the chemical natures of the fluids conveyed, and of the ground itself, vary within so wide a range as to render it necessary to exercise great circumspection in the choice of the materials to be used. Every case must in fact be regarded on its own merits; observing simply that metals are peculiarly liable to decay under the continuous action of dilute acids; and that such decay will be accelerated if any galvanic action should be superinduced. In earth, it may be taken as a general rule that stoneware pipes will last longer than metal ones; that lead will last longer than cast iron, and much longer than wrought iron or wood; and that both on the score of their rapid decay in such positions, and of their compressibility, the pipes made from vegetable substances, such as gutta percha or Indian rubber, are very objectionable for use in the ground. [SEWERAGE; WATER SUPPLY.]

Cast iron pipes are cast vertically in loam moulds; wrought iron pipes are either lapwelded or brazed; lead pipes are either soldered on their longitudinal seams, or they are forced by hydraulic pressure upon a mandril, so as to ensure their perfectly homogeneous character; tin pipes, and copper or composition pipes are usually brazed, but in unimportant works their longitudinal joints may be soldered like those of the lead pipes. The end joints of cast iron pipes are either made with a spigot and faucet joint, which may be either turned so as to fit quite tight, or be left large enough to receive a packing of yarn, white lead, and melted pig lead; or they are made with flange joints connected by means of bolts and washers. The ends of wrought iron pipes may be connected by means of screw couplings, or by flanges; and the end joints of the more easily soldered materials are made by that process, taking care of course to provide against the irregularities of contraction, or of expansion in the pipes. It is precisely on account of the play afforded by the spigot and faucet joints of cast iron pipes, that they are adopted when any danger of changes of temperature exists. As it is not possible to make a screwed joint with any description of earthen pipes, those articles are always made with spigot and faucet joints. The end joints of gutta percha and of Indian rubber tubes are melted, and both the longitudinal or the end joints of leather pipes are sewn or riveted; wood pipes have turned and bored joints fitting into each other, which are sometimes screwed together.

The strength of a pipe must be such as to ensure its resistance to the external and internal pressures it is likely to be exposed to; but, if it should work under pressure, the internal force will be, generally speaking, so much in excess of the external one, that it will suffice to consider the former condition to the exclusion of the latter. The usual formula for calculating the thickness of pipes is as follows: calling p, the pressure per square inch; r, the radius in inches of the interior diameter; and c, the cohesive strength of the metal per square inch; then $x = \frac{p\,r}{c-r}$: Mr. Hawksley adopts a rather simpler formula, namely: $x = 0{\cdot}18\sqrt{d}$; in which d = the diameter in inches. In practice, however, the theoretical thicknesses attained by either of these formulæ are exceeded, on account of the difficulty of securing good sound pipes, when the thickness is very small. Stone and earthenware pipes being usually made of large diameters, and being exposed to great external pressures and jars, seem to require greater thicknesses than are usually given to them; perhaps when their diameter exceeds 9 inches they ought, in the present state of the arts, to be made of such a thickness that the latter dimension should be equal to $\frac{1}{12}$th of the diameter at least.

Rain-water, or other metal descent-pipes are made with projecting ears upon the socket ends, for the purpose of receiving the nails by which they are to be fixed one above another. In these cases the end joints are not required to be fitted hermetically.

PIPE-OFFICE, or more properly the Office of the Clerk of the Pipe, an ancient office in the Exchequer, abolished with that of comptroller of the pipe, by 3 & 4 William IV., c. 99. The records of the office were then transferred to the custody of the king's remembrancer. See the Report of the Commissioners on Public Records, 1837, p. 198.

PIPER, MEDICAL PROPERTIES OF. Pepper. According to the analysis of Pelletier, black pepper contains an acrid soft resin, a volatile oil, piperine, extractive, gum, bassorine, malic, and tartaric acids, salts, &c. White pepper is the same fruit deprived of its outside rind.

The odour of pepper is probably due to the volatile oil, which is not acrid; the pungent taste is most likely owing to the resin. Piperine is generally yellow, from the presence of some resin, to which it is most probably indebted for its virtues, as when purified by means of ether from all resin, it seems devoid of power, and the febrifuge virtues ascribed to it belong in reality to the acrid resin. Pepper is much more employed as a grateful condiment than as a medicine, and it appears to be essential to the process of digestion in hot countries. Of 50,000,000 pounds of pepper collected, one-third only goes to Europe, the greater portion being consumed by the Chinese. Its moderate use with cold raw vegetables or other substances difficult of digestion is to be approved; its employment in excess is hurtful to the liver, and a very large dose may prove fatal, not only by exciting inflammation of the stomach, but by an impression on the nervous system. Black pepper readily poisons hogs.

Whole pepper is a popular remedy against intermittent fevers, and impure piperine is used beneficially in like cases.

Piper betle and piper siriboa, besides the use of them in chewing, are also employed, in the form of the freshly expressed juice, as a febrifuge medicine, and as an antispasmodic, especially against obstinate dry coughs.

Piper methysticum, by fermentation, yields a powerfully intoxicating drink. Matico is yielded by a plant called *Artanthe elongata*, formerly considered a species of piper. [MATICO.]

PIPERIDINE. [PIPERINE.]

PIPERINE ($C_{68}H_{38}N_2O_{12}$?). An alkaloid contained in the different varieties of pepper. [PIPER, in NAT. HIST. DIV.] It was discovered by Oersted in 1819, and is best obtained by the following process.

White pepper, coarsely comminuted, is digested in alcohol, the latter recovered by distillation, and the residual extract treated with a small quantity of solution of potash to remove resinous matter; the resulting impure piperine is washed with water and obtained pure by one or two recrystallisations from alcohol. Piperine occurs in colourless prisms, it is insoluble in cold water, only slightly so in hot water, tolerably soluble in ether, and readily so in alcohol, the essential oils, and acetic acid. Heated to about 212° Fahr. it melts, and at a higher temperature decomposes. Concentrated sulphuric or hydrochloric acids dissolve it, and nitric acid oxidises it to a brown coloured substance, that dissolves in caustic potash with production of a beautiful blood-red colour.

Piperine is but a feeble base. It absorbs hydrochloric acid gas with avidity, a stable hydrochlorate being formed. The *chloroplatinate* ($C_{68}H_{38}N_2O_{12}$, HCl, $PtCl_2$) forms large orange-coloured crystals, very soluble in water or alcohol.

Piperidine ($C_{10}H_{11}N$) is obtained when one part of piperine is distilled with three parts of potash-lime. It is a light oily body that rises to the surface of the distillate on the addition of solid hydrate of potash. It is volatile, boiling at about 222·8° Fahr., colourless when pure, has a powerful ammoniacal odour, and is very soluble in water. Its constitution has not yet been satisfactorily ascertained; it is usually looked upon as ammonia in which two equivalents of hydrogen are replaced by the diatomic radical *piperyl* ($C_{10}H_{10}''$ or Pp''). Piperyl may however be a compound, and contain two radicals ($C_x H_y + C_{10-x} H_{10-y}$), each capable of taking the place of an equivalent of hydrogen in ammonia.

Piperidine forms crystalline compounds with most of the acids. The *hydrochlorate* ($C_{10}H_{11}N, HCl$) occurs in long colourless needles very soluble in water. The *oxalate* ($2\,C_{10}H_{11}N, C_4O, 2\,HO$) also forms delicate needles.

Piperyl-urea, or the *cyanate of piperidine* ($C_2\,(H_2\,Pp'')\,N_2O$ or $N(H_2\,Pp''), O, CyO$), is formed on boiling a solution of sulphate of piperidine with one of cyanate of potash; it may be obtained in long white needles.

Methyl-piperyl urea ($N\,(H, C_2H_3, Pp'')\,O, CyO$) and *ethyl-piperyl urea* ($N\,(H, C_4H_5, Pp'')\,O, CyO$) are produced by acting upon piperidine with the cyanates of methyl and of ethyl respectively.

By the action of the iodides of the alcohol radicals upon excess of piperidine the following bases are produced. They are oily liquids, have fixed boiling points, and form well defined crystalline salts with acids :—

Methyl-piperidine	$N\left\{\begin{matrix} C_2H_3 \\ Pp'' \end{matrix}\right.$
Ethyl-piperidine	$N\left\{\begin{matrix} C_4H_5 \\ Pp'' \end{matrix}\right.$
Amyl-piperidine	$N\left\{\begin{matrix} C_{10}H_{11} \\ Pp'' \end{matrix}\right.$

Excess of the alcohol iodide gives rise to iodides of the following ammoniums. By the usual oxide of silver method these iodides yield hydrated oxides :—

Dimethyl-piperyl-ammonium	$N(C_2H_3)_2Pp''$
Diethyl-piperyl-ammonium	$N(C_4H_5)_2Pp''$

Piperyl-sulphocarbamic acid. Bisulphide of carbon combines energetically with piperidine (Cahours) :—

$$C_2S_4 \;+\; 2C_{10}H_{11}N \;=\; C_{22}H_{22}N_2S_4$$

Gerhardt thinks the product may be piperyl-sulphocarbamate of piperdine, viz. :—

$$C_{22}H_{22}N_2S_4 \;=\; \left.\begin{matrix} N(CS_2)_2Pp'', S \\ NHPp''H, S \end{matrix}\right\}$$

Piperyl-benzamide or *benzopiperide* $\left(N\left\{\begin{matrix} Pp'' \\ C_{14}H_5O_2 \end{matrix}\right.\right)$ is formed on acting upon piperidine with chloride of benzoyl. It may be obtained in colourless prisms.

Piperyl-cuminamide $\left(N\left\{\begin{matrix} Pp'' \\ C_{20}H_{11}O_2 \end{matrix}\right.\right)$ formed from piperidine and chloride of cumyl, crystallises in tables.

PIPERYL-BENZAMIDE. [PIPERINE.]

PIPERYL-CUMINAMIDE. [PIPERINE.]

PIPERYL-SULPHOCARBAMIC ACID. [PIPERINE.]

PIPERYL-UREA. [PIPERINE.]

PIQUETS, or PICKETS. All armies and smaller bodies of men, in camp or bivouac, are protected against surprise by small detachments of troops termed piquets, thrown out on their front and flanks. There are two descriptions of piquets, the outlying and inlying piquets, whose strength depend of course on the length of front to be watched and the liability of attack. The outlying piquet is advanced a considerable distance in front of the camp, while the inlying piquet generally remains in camp ready accoutred to turn out at a moment's notice to support the outlying piquets: communication between the two sets being maintained by sentries conveniently posted for hearing and observing any alarm in front, and if necessary by patrolling to the advanced posts. The general duties of the outlying piquets are to insure the safety and repose of the camp, to gain intelligence of the enemy's movements as early as possible, and even of his intentions by examining the peasantry, and to prevent his making reconnaissances; with this object they are posted with a chain of double sentries in front, on the same principle that light troops are extended to cover a line, with supports in their rear, and if far from the main body with a reserve also. Each company on piquet is divided into three reliefs, one relief being extended on sentry while the other two are in support, the sentries being relieved every hour during the night. As a further precaution against surprise, and as a means of obtaining information, frequent patrolling is directed along the front of the line of sentries, and, if the enemy's posts be far off, along the roads in their direction, as far as is deemed expedient. These patrols are preceded by feelers, quick intelligent men; and, avoiding all unnecessary firing, so as not to create false alarms, retire steadily, and if possible unobserved, on the piquets, on finding themselves in presence of the enemy. A strong patrol should always be sent out about an hour before daylight, when the whole of the advanced piquets are also got under arms, as this is the time when an attack is most likely to be made; for this reason, also, piquets are generally relieved at this hour, as a great accession of force is thus obtained. In the daytime the sentries should be on high ground, the better to observe the enemy's movements; whilst at night they should have the highest ground before them, in order to see an approaching party against the sky without being themselves seen. The duties of officers in command of piquets is to give immediate information of any signs indicating the intention of the enemy to make an attack, such as a strengthening of the outposts, unusual movement of troops, noise of artillery on the march, &c. Should an attack be made, the object of the piquets is by all means in their power to gain sufficient time to enable the main body in their rear to get under arms and prepare for action. Hence the posts should be strengthened by breastworks, abbatis, &c., which the piquet should defend as long as its flanks are not attacked. It is not the object of piquets that they should defend themselves to the last, or shutting themselves up in a house or enclosure be cut off, but rather that they should retire steadily on the main body, disputing every available obstacle; but, at the same time, in an extreme case an officer must remember that it is his duty to sacrifice himself rather than be driven in on the main body before it has had time to form.

PIRACY (immediately from the Latin *pirata*, and remotely from the Greek πειρατής) or robbery and depredation on the high seas, is an offence against the universal law of society; a pirate being, as Blackstone expresses it, "hostis humani generis." "With professed pirates," Lord Stowell observes (2 Dods., 244), "there is no state of peace. They are the enemies of every country, and at all times; and therefore are universally subject to the extreme rights of war."

Molloy, an ancient writer on maritime law, but whose doctrine it would be dangerous to adopt in these days, says, "If a piracy be attempted on the ocean and the pirates are overcome, the captors may immediately punish them with death, and not be obliged to bring them into any port, provided this occurs in places where no legal judgment can be obtained. So likewise if a ship be assaulted by pirates, and in the attempt they are subdued and taken, and carried into the next port, if the judge openly rejects their trial, or the captors cannot wait till judgment shall be given without certain peril and loss, they may do justice on them themselves without further delay or attendance." (Molloy, 'De Jure Maritimo,' chap. iv., sect. 12, 13.)

"There is said to be a fashion in crimes; and piracy, at least in its simple and original form, is no longer in vogue. There was a time when the spirit of buccaneering approached in some degree to the spirit of chivalry in point of adventure; and the practice of it, particularly with respect to the commerce and navigation and coasts of the Spanish American colonies, was thought to reflect no dishonour upon distinguished Englishmen who engaged in it. The grave judge (Scaliger) observes, in a strain rather of doubtful compliment, 'Nulli melius piraticam exercent quàm Angli.'" (Lord Stowell, 2 Dods., 374.)

The offence of piracy, by the common law of England, consists in committing those acts of robbery and depredation upon the high seas, which, if committed upon land, would have amounted to felony there. But by various statutes other offences are made piracy, especially dealing in slaves. (See on this point, Blackst. 'Com.' Mr. Kerr's ed., vol. iv.; and Abbott, 'On Shipping,' 140, 141, 142, 239.)

Persons guilty of piracy were formerly tried before the admiralty court, according to the rules of the civil law. This was altered by the statute 28 Henry VIII., c. 15, which enacted that the trial should be before commissioners of oyer and terminer, and that the course of the proceedings should be according to the common law. Further provision was made by the statutes 39 Geo. III., c. 15; 43 Geo. III., c. 113; 46 Geo. III., c. 54; and now, by the stat. 4 & 5 Wm. IV., c. 36, sec. 22, the trial of offences committed on the high seas is before the Central Criminal Court, or the judges at the assizes.

PISCES (the Fishes), the last constellation of the old zodiac. There is in the mythological stories (which are unworthy of note) a confusion between this constellation and Piscis Australis, presently to be noticed. (See Grotius, in his notes on Aratus.) The constellation consists of two fishes linked by a string attached to their tails: they are not close together, the upper one being close to Andromeda, the lower one under the wing of Pegasus. The rectangular figure mentioned in PEGASUS will be a guide to the position of the two fishes: the line of α Andromedæ and γ Pegasi being parallel to the body of one fish, and that of γ Pegasi and α Pegasi to the body of the other.

The principal stars are as follows :—

Character.	No. in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.
γ	6	8105	4
δ	63	222	4
ε	71	288	4
η	99	453	4
α	113	625	3

PISCIS AUSTRA'LIS, or AUSTRI'NUS, or NO'TIUS (the Southern Fish), one of the old constellations situated directly under Aquarius: the stream from the water-pot of the latter constellation finishes at the mouth of this fish. It contains a remarkable star of the first magnitude, Fomalhaut, which only just rises above the horizon in these latitudes; when on the meridian, it is nearly in the same vertical circle with α and β Pegasi.

The principal stars are as follows :—

Character.	No. in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.
ι	9	7557	4
θ	10	7583	4
β	17	7842	3
ε	18	7898	3½
α	24	7992	1

PISCIS VOLANS (the Flying-Fish), one of Bayer's southern constellations, situated between the South Pole and Argo. It contains no stars of conspicuous magnitude.

PISTOL. [Arms.]

PISTOLE. [Money.]

PISTON. [Hydraulics; Steam-Engine.]

PITCH. [Tar.]

PITCH IN MUSIC. [Acoustics; Tuning.]

PITTACAL. [Tar.]

PIVOT, in military manœuvres, is the officer or soldier stationed on the flank of a section, company, battalion, &c., on which it wheels.

PIX, TRIAL OF THE. [Coinage.]

PLACES OF ARMS, in fortification, are the enlargements in the covered way [Bastion] at the re-entering and salient angles of the counterscarp; the latter are termed *salient* places of arms, and are simply made by rounding the counterscarp; and the former, the *re-entering* places of arms, are formed by setting off demi-gorges of about thirty yards, and making the faces form angles of 100° with the adjoining branches of the covered way, as in Vauban's first system. These places of arms receive a considerable development in various systems, as in the modern system, where they are large and furnished with redoubts, and in the system invented by Chasseloup de Laubat, and called after him, where they form one of the principal points of defence.

PLAGAL, a term in old ecclesiastical music, relating solely to the Canto-Fermo, or Plain-Song, and signifying *collateral.* When the octave was so divided that the fifth was above the fourth, the mode or key was said to be *Plagal.*

PLAGUE. [Pestilence.]

PLAID, a chequered woollen cloak or mantle, the garb of the highlanders of Scotland, but worn also in that country by many of the lowlanders. In Gaelic it is termed *breacan-feile*, the chequered, spotted, or striped covering. The chequered patterns, by their varied colours, indicated among the highlanders the peculiar clan to which they belonged, and a detailed account of the patterns is given by Mr. R. M'Ian, in his 'Clans of Scotland Illustrated.' It was a part of the dress proscribed by the act of parliament of 1747, after the rebellion of 1745. The restriction was, however, afterwards repealed, and the plaid was made part of the uniform of what were called the highland regiments. It is also worn by the pipers of the Coldstream guards.

But the term plaid was not confined to the chequered cloth. Mr. Logan, in his 'History of the Gael,' says that it was frequently "woven of one colour, or an intermixture of the black and white, so often seen in Scotland to the present day." This was the shepherd's plaid, worn even yet by lowlanders, and sometimes called the maude. Jamieson, in his 'Popular Ballads,' calls it a sort of blanketing. It was also used by females, both as a shawl or mantle, and for other parts of dress. Thus Ramsay, in his 'Gentle Shepherd,' says that his heroine, Peggy, shall "change her plaiding coat for silk." The old "belted plaid" of the highlanders consisted of twelve yards of stuff, wound round the body, and girdled round the waist by a leathern belt, the upper end being left loose and thrown over the left shoulder, to which it was frequently fastened by an ornamental brooch.

PLAIN-CHANT. [Plain-Song.]

PLAIN-SONG, or *Cantus Firmus* (Lat.), or *Canto Fermo* (Ital.), a name given by the Church of Rome to the ecclesiastical chant. The *Plain-Song* is an extremely simple melody, if melody it may be called; it admits but one measure, the duple, and only notes of equal value. It is rarely allowed to extend beyond the compass of an octave, and never exceeds nine notes; and the staff on which the notes are placed consists of but four lines. The clefs are those of C and F. To St. Ambrose, archbishop of Milan, the church is supposed to be indebted for the regular form of the Plain-Song, and to the Pope St. Gregory, surnamed the Great, for having perfected and brought it into that state in which it still continues to be used in the Roman Church.

PLAINS. All those parts of the dry land which cannot properly be called mountainous are plains, and such compose by far the greater part of the earth's surface. Thus, for instance, it has been estimated that in South America the plains are to the mountainous country as 4 to 1. We are not aware that a similar calculation has been made for the other parts of the world, nor are there perhaps materials sufficiently exact for the purpose.

The word plain has but an indefinite meaning of itself, and seems to be rightly understood only when used in opposition to the word mountains, or when conjoined to the name of some known place, in which case it means the country itself so designated, or the environs of some particular spot. Thus we speak of the cities of the plains, the valleys of the plains, the plains of Lombardy, the plains of Quito, &c.

It were a great error to imagine that by the word plain a perfectly horizontal surface is always understood. In its usual acceptation it means a greater or less extent of country, flat in its general level as compared with a mountainous country. The more perfectly even and horizontal the surface, the better does it deserve to be called a plain, such as the plains of Venezuela and of the lower Orinoco, Mesopotamia, &c. But the surface of the ground may be gently waving, as Salisbury plain and the Ukraine; or more prominently undulated, as the plain round Paris; or it may be studded with hills, as the plains of the Cassiquiare; or it may be traversed by valleys more or less wide and deep, like that part of France which lies between the Loire and the Garonne; or intersected with deep ravines, as the central plains of Russia, without ceasing on such accounts to be a plain.

Plains have been divided into two classes, high and low; but a moment's reflection will show that such denominations can apply rigorously only to the two extremities of a scale of elevation, at the bottom of which would stand, for example, the delta of Egypt or the llanos of South America (which latter are raised only about 150 feet above the level of the ocean, and in some places even less), and at the top the plain of Antisana, 13,435 feet above the sea-level; whereas the greater number of plains are found at intermediate heights, as the following will show :—

	Feet above the Ocean.
The plains of Hungary	200 to 250
The extensive plains on the north of the old continent from the Scheldt to the Yenisei . . .	250 to 300
Plain from which the Himalayas rise (average) .	300
Plains of Moscow	460
Prairie in lower parts of Illinois	400 to 550
Plains of Lombardy	500
Plains of Lithuania	600
Suabia	900
The plateau of Valdai	1000
Auvergne	1100
Prairie of Southern Wisconsin	1100
Plains of India skirting the Himalayas, highest .	1200
Switzerland between the Alps and Jura . .	1400
Steppes of the Kirghis	1300 to 1600
Bavaria	1650
Plains of the two Castiles	1800 to 2100
Mysore	2300 to 2600
Table-land of Persia	3800 to 4200
Westernmost Prairies of Missouri . . .	5000
Eastern edge of the table-land of Abyssinia . .	7000 to 9000
Plain of Antisana	13,435
Table-land of Asia in Tibet	15,000

Though we generally regard those plains which are the least raised above the surface of the ocean as the lowest, it must not be forgotten that round the Caspian and Aral there are plains of many thousand square miles considerably depressed below the sea-level; as is also the case with the plain or valley of the Jordan.

The term *plateau* has often been given exclusively to elevated plains; but this also is incorrect, inasmuch as by a plateau is sometimes meant a great extent of country considerably raised above the rest of the land, and having its mountains, its plains, and its valleys, as is particularly exemplified in the minor plateau of Albania, and in the great plateau of Central Asia, described below.

Table-land, properly so called, is an elevated plain rising more or less abruptly from the general level of the country, and being, as it were, the broad and horizontal or gently undulating top of an immense mountain, as the Nilgherry district of India. Sometimes there are several such, set one upon the other, at least on one or two sides, when they are called platforms or terraces, as those on the eastern slope of the Cordillera of New Mexico.

Some writers regard the words plateau and table land as merely the French and English names for the same sort of elevation. Humboldt is of opinion that these names should be confined to elevations producing a sensible diminution of temperature, and, accordingly, to such heights only as attain to 1800 or 2400 feet. Some again, as Balbi, give the name of plateau to all high and extensive mountain-tracts.

Generally speaking, the plains of Europe are of middling elèvation, the extremes of high and low being principally found in Asia and America. Thus while the great plains of Central Asia, about Ladak, Tibet, and Katchi, and round Koukounoor and elsewhere, attain a height similar to those of Quito and Titicaca, or from 9000 to 12,000 and 15,000 feet, the great marshy plains of Siberia along the borders of the Frozen Ocean are very slightly raised above the sea-level, as is also the case with the plains of Bengal at the mouths of the Ganges, the whole of Mesopotamia, the Tehama of Arabia, &c.

The plains of India which skirt the foot of the southern face of the Tibetan table-land, for an extent of 1500 miles, nowhere have an elevation exceeding 1200 feet above the sea, the average being much less. "The greater part of the country between" the Sikkim Himalaya, forming part of that face, and the sea, as we are informed by Dr. Joseph D. Hooker, "is a dead level, occupied by the delta of the Ganges and Brahmaputra, above which the slope is so gradual to the base of the mountains that the surface of the plain from which the Himalayas immediately rise is only 300 feet above the sea." We have every reason to suppose that the plateau of Yarkend and Khotan, on the northern border of the table-land, like the country around Bukhara or Bucharia, lies at a very small elevation, probably not more than 1000 or 2000 feet above the sea, while the surface, as we know, and in agreement with a previous statement in this article, descends on the borders of the Caspian to 80 feet below that level.

The table-land of Tibet itself is the summit of a great protuberance above the general level of the earth's surface, of which the Kouenlun and Himalaya are the north and south faces, while the other mountain-ranges and intervening valleys commonly marked on our maps of Tibet are but corrugations of the table-land more or less strongly marked. In its general relief, however, the table land is laid out horizontally, at a mean elevation of 15,000 feet. The Indus and Brahmapootra rivers maintain a course along the length of the summit of the table-land, and receive as they proceed the drainage of its entire breadth, with the exception, first, of an occasional strip along its southern edge, from which the water passes off more or less directly to the north through the Himalaya; and secondly, of some parts chiefly found in the northern half of the table-land, from which the water has no escape, but is collected in lakes in depressions on its very summit. The waters accumulated in these two streams are at length discharged by two openings in the Himalayan slope, through the plains of Hindostan, into the Indian Ocean. None of the drainage of the table-land, so far as is known, passes in the opposite direction through the northern slope. The waters of that slope itself exclusively flow down to the plains of Yarkend.

That portion of the table-land which forms a plain along the upper course of the river Sutlej, we are informed by Major R. Strachey (to whose researches, and those of his brother Captain H. Strachey, much of our present accurate knowledge of these regions is due), "lies immediately to the north of the British provinces of Kumaon and Gurhwal, and is about 120 miles in length, its breadth varying from 15 to 60 miles. Its surface, to the eye a perfect flat, varies in elevation from 16,000 feet along its outer edges, on the south-west and north-east, to about 15,000 feet in its more central parts, where it is cut through by the river Sutlej, which flows at the bottom of a stupendous ravine, formed out of the alluvial matter of which the plain is composed to a depth of 2000 or 3000 feet, and at its west end even more." But the table-land itself, it must be remembered, is a mountain-mass. "The so-called *plains*" of Tibet, Dr. Hooker remarks, "are the flat floors of the valleys, and the terraces on the margins of the rivers, which all flow between stupendous mountains," either those of the northern and southern slopes or faces, or of the corrugations already mentioned.

In South America, contrasting with the lofty plains of Quito, of Santa Fé de Bogota, &c., are the llanos and the plains of the Amazon; while in North America, the interminable prairies and the low swamps round New Orleans form a striking contrast with the Rocky Mountains and the elevated plains of Mexico.

Of Africa comparatively little is known; but if the plains of Lower Egypt and part of the Sahara are very low, there are high plains in some of the mountainous regions.

The great plateau or table-land of eastern Africa, according to Dr. Beke, to whose continuation southward of Dr. Rüppell's investigations we mainly owe our present knowledge of it, begins to the south of the country of Taka, in about 15° of north latitude, where the anticlinal axis between the Nile and the Red Sea rises rapidly till it attains an elevation of 7000 or 8000 feet above the level of the ocean. At Halai, at the summit of Mount Taranta, not more than eighteen geographical miles from Zulla (the ancient Adule, recently, 1860, taken possession of by the French government), near Massowah, the edge of the table-land has an absolute elevation of 8625 feet, which gives a rise of 1 in 12·7, equal to an angle of 4° 30′ with the horizon, to the eastern slope of the table-land (or, as it may be more correctly called, in Dr. Beke's opinion, broad mountain-chain of Abyssinia). The western counter-slope towards the interior of the continent has a fall of 1 in 343·7 only, giving an inclination of 10′; consequently, on a direct line from east to west along the fifteenth parallel of north-latitude, the eastern slope of the Abyssinian mountain-chain (or table-land) towards the sea is, to the western counter-slope towards the Nile, as 29 to 1. But on a line corresponding with the courses of the principal rivers from south-east to north-west, the eastern slope has a rise of 1 in 35·83, equal to an angle of 1° 41′, and the counter-slope of 1 in 460, or 7′ 30″, giving the proportion of 11·8 to 1. In making this estimate, however, the rise of the eastern slope is not taken from the level of the sea, but from that of the river Hawash, which is the recipient of the waters of the eastern slope as the Nile is of the western, and has itself an absolute elevation of 2200 feet, at a point distant from the sea about 200 miles. This, again, gives a fall of about 1 in 550, equal to an angle of 6′ 15″, for the eastward dip of the comparatively low-level country between the Hawash and the Indian ocean. "As regards the counter slope of the Abessinian (Abyssinian) chain," Dr. Beke says, "it would seem that the fall of the land towards the Nile in the western portion of it is considerably greater than it is in the eastern; so that the surface of the table-land, or broad summit of the mountain chain, approaches more nearly to a level than if the slope were the same throughout. It is certain, however, that the table-land nowhere forms an absolute level, and that the general dip westward commences from its extreme eastern limit."

This table-land, as the same geographer has shown, may, in the most general way, be compared with those of the Indian peninsula and South America, but with this difference: the Western Ghauts in the former, and the Cordilleras of the Andes, present their principal acclivities towards the west, and thence slope gradually eastwards; whereas the African plateau rises abruptly on its eastern side, and has its western counterslope towards the interior of the continent and the valley of the Nile. Another point of difference is, that while the rivers which rise near the western edge of the Ghauts and of the Andes take their courses eastwards over the counter-slopes, at right angles with the water-parting (commonly called the water-shed) [WATER-SHED] or nearly so, and discharge their waters into the ocean—the streams which have their sources at the water-parting of eastern Africa flow in a general north-westerly direction, and fall into the Nile, which skirts the lengthened western counter-slope. To these comparisons of Dr. Beke, it may be added that the general structure of the African plateau resembles that of Tibet, described above. While the principal direction of the latter, however, is from east to west, its slopes being on the north and south—the principal direction of the former, as we have seen, is from north to south, the slopes being on the east and west. But, *mutatis mutandis*, accordingly, the resemblance between the great table-lands of Africa and Asia is closer, we think, than that of the former to the elevated country bounded by the Ghauts and the Cordilleras respectively. In this comparison the Indus and the Brahmaputra correspond to the Nile itself, while their main tributaries, the Jumna, Ganges proper, &c., answer to the streams which fall into the Nile, as already mentioned, from the south-east. The structural resemblance between the table-lands of the two great continents is also very near in another respect, allowing for the different distribution of dimensions. In the southern extension of the African plateau, the rivers flow through deep transverse valleys, forming openings through the eastern slope into the low country at its base, and thence into the ocean; just as the waters accumulated in the two great Indian rivers are discharged by openings in the Himalayan or southern slope of the Asiatic table-land, through the plains of Hindostan, into the ocean.

The African table-land, as a whole, may be described as a succession of extensive undulating plains (like the corrugations and so-called plains of Tibet, already mentioned), but dipping very gradually towards the west and north-west, and intersected by numerous streams, which, after a short course over the surface of the plateau, fall abruptly into the deep-cut fissures or valleys just noticed, in which they soon reach a depression of 3000 to 4000 feet below the general level of the table-land. In addition to the irregularities produced by these valleys, the uniformity of the surface is broken by loftier mountain-masses, which in some parts of Abyssinia attain an absolute elevation of from 11,000 to 15,000 feet. The eastern edge of the plateau itself has been clearly traced as far as the ninth parallel of north latitude, to which distance it forms the water-parting between the basins of the rivers Nile and Hawash. "How much further it extends southward," Dr. Beke remarks, "our present knowledge scarcely enables us absolutely to determine; but we may safely regard it as reaching beyond the equator." The snowy mountains observed by Captain Short, and those discovered by the missionaries Krapf and Rebmann south of the equator, appear to be connected with the broad mountain range of eastern Africa, of which the Abyssinian table-land forms the northern portion. These are the "Mountains of the Moon" of the natives and of the ancient geographer Ptolemy, which Dr. Beke has proved to be thus a meridional and not an east and west chain, in which are the sources of the Nile, and which form the eastern face of the table-land in its southern extension. The continuation of this range was crossed as far south as 7° 30′ south latitude by the recent travellers, Captains Burton and Speke. Detailed information on the whole of this subject, with maps and sections of the country, will be found in Dr. Beke's work entitled 'The Sources of the Nile,' London, 1860; from which, except as otherwise indicated, and with slight variations of description, the preceding view of the African table-land has been derived.

Plains differ not only in their elevation, but in the horizontality of their surface and general slope, and in the nature of their soil; which circumstances, together with their geographical position, influence their climate and productions, and give to the most considerable among them a particular character and physiognomy. It may be remarked that the rocky and sandy plains belong almost exclusively to the hot and temperate regions of the old world. The plains of America are generally characterised by their gramineous covering or their vast forests; the Asiatic steppes by a twofold appearance, being in some parts studded with low saline plants, and in others, as in southern Russia, Siberia, and Turkistan, covered with plants of the families of the *Compositæ* and *Leguminosæ*; while the greater part of the European plains are richly cultivated.

We say such are the general characteristics, for there are plains of similar character and physiognomy in very different and widely separated regions of the world. The high land of the Campos Parexis, for instance, in South America, is very similar in physiognomy to the desert of Gobi in Asia. The *Desiertos*, near Coquimbo, are of the same character as the Sahara. The *Pussta* of Hungary resemble the savannas of the New World; and the pampas of Cordova are not unlike some of the Siberian steppes.

Though, as we have said, plains constitute by far the greater portion of the earth's surface, and are very varied in their appearance, there are nevertheless some which are remarkable not only for their extent, but for the peculiarities which distinguish them; peculiarities derived, no doubt, in part, from the circumstances attending their original formation, and which no subsequent causes have been able to obliterate. These remarkable plains are known under the names of deserts, landes and heaths, steppes, savannas and prairies, llanos, pampas, and selvas (or forest plains) of the Marañon. DESERTS having been already described under their particular head, we shall here give a brief account of the others.

Heaths and Landes of Europe.—From Paris to Moscow and Casan on the one hand, and to Astrakan on the other, is one continued plain, comprising the lowlands of Northern France, the Netherlands, the North of Germany, the whole of Prussia, and the greater part of Poland and Russia, as far as the first terraces of the Ural. Besides which there are many minor plains, as those of Wallachia and Bulgaria, Hungary, Lombardy, &c. The ancient civilisation of Europe has covered the greater part of its plains with cultivation and rendered some of these lands the richest in the world (the plains of Lombardy); nevertheless there are some spots which seem to defy all human efforts to bring them into cultivation; such are those between the Lower Volga and the Ural, of which we shall speak more fully in describing the steppes, and such are the heaths and landes. Of these, next to those of Russia, the most extensive are in Lapland and west Gothland. But the chief landes and heaths, properly so called, lie in the north-west of Germany. In Lower Silesia, Lusatia, and Brandenburg, there is little else than sand, and also in Pomerania and Mecklenburg, studded with a few hills, numerous lakes, and, along the maritime parts of the latter, having some woods of oak. In Hanover the gentle acclivities are covered with heath, which extends through part of Holstein to the centre of Jutland. The most sterile parts of Hanover however are the landes of Lüneburg and Verden between the Elbe and the Weser, and those of Meppen on the right bank of the Ems. Those of Luneburg and its vicinity are said to cover a space of about 6000 square miles. These landes are covered with heath, with pine woods, and marshes. On the west of the Ems, about Bentheim, there are also extensive landes covered with swamps and stagnant pools. In the province of the Lower Rhine, in the environs of Monjoie, between Eupen and Malmedy, we again find vast landes coated with heath. In France, of which country about one-twelfth is unproductive soil, there are extensive landes and barren spots. That tract which extends eastward from the right bank of the Adour, and gives its name to the department, consists almost wholly of pools, marshes, and heath, and this sterile plain extends a great way into the department of the Gironde. The shingle plain of Crau, in the department of the Bouches du Rhone, is well known, and likewise the sterile chalky plain of La Champagne Pouilleuse. In the kingdom of Naples there are considerable landes.

Steppes.—This name, which is Russian, is given more particularly to the extensive plains which lie on the north-west of Asia. Considered as a whole, the steppes have a character quite different from the other great plains of the world, though in different parts they present partially the distinguishing features which characterise the llanos, the savannas, the pampas, the sandy deserts, &c. Generally speaking, they consist of rich pastures intermingled with woods, barren sands, muriatiferous clay, and abounding in lakes, pools, and streams of salt and bitter waters.

From the sea of Azof on the west to the foot of the Little Altaï on the east, there is a band extending, in a north-east direction, from the mouth of the Kuban towards Torusk, where the undulations of the plain prevent the egress of the waters, which, percolating through a highly saline soil, are collected in the hollows into innumerable lakes and pools of salt water, which give a peculiar feature and interest to these steppes.

Farther northward, the Siberian plains have a general slope towards the Frozen Ocean, and are intersected by the great rivers Obi, Yenisei, and Lena; between the lower courses of which extend immense frozen marshes, covered with moss, and interspersed with a few sandy and clayey hills crowned with tufts or clumps of stunted birch and other dwarf shrubs.

The greater part of what are properly called the steppes form a considerable part of the country known as Independent Tartary, which is inhabited by the nomadic hordes of the Kirghis Cossaks.

The steppe which lies on the north-west of the Caspian, bounded by the Caucasus, the sea of Azof, the lower course of the Don, and thence to the Ural or Iaïk, is inhabited by the Cossaks of the Black Sea and the Nogay Tartars. The whole of this steppe is characterised as composed of hills of a moving shelly sand, between which are beautiful green pastures, and marshy hollows with reeds and clumps of trees, among which are willows, poplars, and the wild olive. There are numerous salt streams and brine pools, barren patches covered with a saline efflorescence, and in many places tufts of saline plants. The fertility of the hollows seems due to a sheet of water which, coming from the hilly range called Obstcheï Sirt, a branch of the Ural, flows immediately below the sandy surface, being probably retained by an impervious substratum.

Between the Iaïk on the west and a low ridge of hills on the east, which may be regarded as a south-eastern continuation of the Ural, and which extends between the Aral and the Caspian, is another steppe similar in character to that already described. It is occupied by the Kirghis of the little horde; while what is called the central or middle horde ranges over the vast steppe contained between the lake Aral and the Sir on the south, the low hills already mentioned on the west, the Ouloustaou and Naourgiuskaia ranges on the north, and the Sarasou on the east. With the exception of the Sir, all the waters of this great basin lose themselves in the sand, or in lakes more or less salt, the principal of which is the famous Aksakal Bari.

To the north of the last-mentioned steppe lies the great steppe or plain of Ischim, which extends from the eastern slope of the southern extremity of the Ural, across the Tobol, to the Irtish. It takes its name from the river Ischim, which, dividing it nearly in two, falls into the Irtish near Petropavloffskoi. The north-east part of this steppe towards Tara, on the left bank of the Irtish, is covered with dense forests abounding in game and rich in firs.

Crossing the Irtish, we enter the great steppe of Baraba, occupying all the space between that river and the Upper Obi. This steppe, lying nearer the foot of the mountainous district of the south and east, contains numerous lakes and pools, particularly in its southern portion. This district is in many places extremely fertile, and along the water-courses the grass grows luxuriantly. The north and north-west parts are wooded, but the more southern, those lying along the Irtish and towards the Altaï, have few trees, and are less fertile. The lake Tschany, the largest and nearly the most northerly of the great group of lakes, abounds in fish; the surrounding country is extremely fertile, and abounds in aquatic game, the chief nourishment of the Tartar tribes who live dispersed along the frontiers of this canton. Interspersed with the sandy, barren, and saline spots, are many places where there is excellent land for tillage, in which grain and flax succeed well. The Kirghis of the great horde occupy a more mountainous country to the south of the Sarasou.

Besides these great steppes, there are numerous other patches of greater or less extent and similar general character in Central Siberia, reaching from the Ural to the Lena.

Previous to the subjection of the wandering hordes to Russia, that country had lines of fortified posts for its protection against these predatory bands; but now that the different hordes of Kirghis acknowledge the supremacy of Russia, and their several chiefs are paid by the Russian government, many of these posts have been abandoned, and open villages are now multiplying along the roads by which the Russian caravans travel towards Kiachta and in the direction of the mining districts of the Altaï. The inhabitants of these villages, some of which are very large, are the only stationary population of the steppes. The wandering tribes are very numerous, and are continually shifting their ground to find food for their numerous cattle, consisting of horses, camels, horned cattle, sheep, and goats.

The extent of the steppes properly so called, excluding the marshy plains of the north, may be about 1,000,000 square miles.

Savannas or Prairies.—The central part of North America, from the Frozen Ocean to the Gulf of Mexico, may be regarded as one continuous plain, divided by a low water-parting into the north-eastern basin, whose waters flow into the Polar Sea, Hudson's Bay, and, by the great lakes and St. Lawrence, into the Atlantic, and the basin of the Missouri and Mississippi whose waters fall into the Gulf of Mexico.

This immense tract of country, estimated by Humboldt at 2,430,000 square miles, is extremely varied in climate, in character and productions; for while the northern portion which is watered by the Mackenzie, Back's River, the Churchill, and the Saskatchewan, is condemned for the greater part of the year to all the horrors of an iron-bound soil and stunted polar vegetation, palms and other tropical trees grow at the extremity of the southern portion. It is this southern basin, watered by the mighty Missouri and Mississippi, with their abundant affluents, that contains those extensive grass-covered tracts, the savannas and prairies. They lie chiefly on the western side of the Mississippi, though along the Illinois river they are found to the extent of 1,200,000 acres, and also in other parts of the basin east of the Mississippi. But the whole of the territory from the right bank of the Mississippi to the mountains is not one continued savanna, or even an unbroken horizontal plain; for it rises towards the mountains, many of whose spurs are reached by the Missouri, which has eroded their extremities into bluffs. These ridges form the boundaries of the basins of the great tributary streams, the Platte, the Kansas, the Osage, the Arkansas, &c. Woods are also occasionally met with along the Mississippi and other watercourses, as likewise in Arkansas; and in some places, as between the Platte and the Missouri, there are extensive surfaces of moving sands resembling those of the African desert. Elsewhere again, as from the mouth of the Arkansas along the Mississippi, a distance of 450 miles long and 40 miles broad, the soil is all swamps and pools, with abundance of trees: this is also the case above Illinois lake and elsewhere. Along the upper Missouri, from the territory of the Mandans, is an interminable plain without trees or shrubs except in the marshy spots. In various parts, but more especially along the borders of the great plain, and in Arkansas, salt is found.

The savannas, or prairies, as they are also called, are divided by Flint, an American writer, into three kinds:—1, the heathy or bushy, which have springs and are covered with small shrubs, grape-vines, &c., very common in Indiana, Illinois, and Missouri; 2, dry or rolling (a designation which will be explained in the sequel), generally destitute of water and almost of all vegetation but grass; they are the most common and extensive: the traveller may wander for days in these vast and nearly level plains without wood or water, and see no object rising above the horizon; 3, the alluvial or wet prairies, the smallest division; they are covered with a rich vegetation of tall rank grass. The soil is deep, black, friable, and fertile, and abounding in pools without issue, left by the floodings of the rainy season. It is over the second kind chiefly that the bisons wander in herds of from 40,000 to 50,000. Stags, or more properly wapitis, are also very numerous; and between the Arkansas and Red rivers there are droves of wild horses. Deer are also numerous; and along the borders of the Missouri, above the Platte, or shallow river, the antelope abounds in herds of several hundreds. In summer wild goats are seen in vast numbers along the Mississippi. Above the Mandan villages are grizzly bears; and badgers, beavers, otters, foxes, wolves, racoons, opossums, squirrels, porcupines, and skunks inhabit the same region. To this enumeration of Warden's and Flint's, Lyell adds the jaguar. The waters teem with alligators and tortoises, and their surface is covered with millions of migratory water-fowl, which perform their annual voyage between the Canadian lakes and the shores of the Mexican Gulf.

Precise information on the extent and peculiar characters of the Prairies, obtained in an elaborate survey, has recently been given by Mr. James Hall, state geologist of Iowa, a man of science advantageously known to English geologists. This is introduced in an account of the physical geography of that region, forming Chapter I. of Mr. Hall's 'Report on the Geological Survey of the State of Iowa,' published by authority of the legislature of that state, 1858. It involves many particulars having an important bearing on the structure of the plains of North America in general, and with some slight omissions we shall now transfer it to our columns. Fortunately for the investigation of this subject, the state of Iowa consists, mainly, of prairie country.

The prairie region of the west occupies a vast extent of country, extending over the eastern part of the Ohio, Indiana, the southern portion of Michigan, the southern part of Wisconsin, nearly the whole of the states of Illinois and Iowa, and the northern portion of Missouri, and gradually passing, in the territories of Kansas and Nebraska, into the arid and desert region which lies at the base of the Rocky Mountains, called—in that local technicality which is so characteristic of America, and which, in every part of the world appears to have preceded scientific geographical description—*the Plains*. This passage takes place in the region between the parallels of 97° and 100°, west of which belt the country becomes too barren to be inhabited and worthless for cultivation. The passage from the heavily wooded region of the north and east into the treeless plains of the west is a gradual one, and the disappearance of the underwood and the predominance of "oak openings," or groves of oak and other forest trees, not crowded together, but scattered over the surface at a considerable distance from one another, without any low shrubs or underbrush between them, is the characteristic of the border of the prairie region. To one coming from the dense thickets of low and tangled shrubs which choke the forests of the north, and render travelling through them difficult, even to the pedestrian, the open woods of the north-west offer a striking contrast to that which has been left behind, and form a natural introduction to the grassy plains or prairies.

The elevation of the prairie region above the level of the sea gradually increases from the east to the west. The lower part of Illinois varies from 100 to 250 feet above the river at Cairo, or 400 to 550 feet above the sea-level. In the central portions of the state the levellings along the line of the Illinois central railroad, indicate an average elevation of from 650 to 750 feet, which increases towards the northern boundary to 800 or 900 feet above the sea. Some of the highest swells of the prairie attain an elevation of nearly 1000 feet. The more elevated portions of Southern Wisconsin are about 1100 feet above tide-water. The region from the Mississippi westward is a gradually ascending plain as far as the very base of the Rocky Mountains. Within the limits of Iowa the table-land along the water-parting between the streams flowing into the Mississippi and the Missouri, the "Plateau du Coteau des Prairies" of Nicollet, attains the altitude of from 1400 to 1500 feet above the sea; and to the west of the Missouri the ascent still continues, the soil being more and more arid, until at the 105th meridian, an elevation of 5000 feet is attained.

The prairie is designated as "flat" or "rolling," its surface in the one case being nearly level, and in the other gently undulating. The flat prairie is found chiefly south and west of Lake Michigan, on the head-waters of the Illinois and Wabash rivers. In other districts the rolling prairie greatly predominates over the flat, especially in Iowa, where there are but few tracts of any extent which are not more or less undulating. Even in the rolling prairie the irregularities of the surface are but trifling in amount, compared with the vast extent which can be taken in at one view: so that it often happens that a region which, seen from a distance, appears to be almost a dead level, is, in reality, furrowed by broad depressions, which give a wave-like character to its surface. Thus, the traveller crossing the prairie in any direction except along its water-parting, will be surprised to find himself constantly ascending and descending, although only hills of moderate elevation. The depth of these depressions below the mean level of the prairie may frequently be as much as 50 feet; but it does not often greatly exceed that amount, without the drainage becoming sufficient to convert the water, which collects in them, into a running stream. The "swales," or "sloughs," of the prairie, as these depressions are called, are wet and marshy except in the dry seasons, and, in the spring and autumn make the roads almost impassable.

The prairies are covered with a dense vegetation of grass and herbaceous plants, to the almost entire exclusion of trees, which occur only under peculiar circumstances of moisture and soil, in scattered groups called groves, or along the larger streams, or, occasionally, on low rocky ridges which are sometimes met with. This growth of timber in the river bottoms does not entirely disappear until we reach the border of the "plains," in the longitude of about 98° west of Greenwich. In the swales or depressions, which are comparatively humid, the grass grows very tall and rank; and the higher and drier the prairie the finer its growth, and more dense and closely interwoven the sod. Among the grasses of the prairies is interspersed a great variety of flowering plants, which bloom in constant succession from spring to autumn, and lend a peculiar charm to the landscape, giving beauty and variety to what might otherwise be called a monotonous scene. The characteristic herbs of the prairies would seem to be compositæ, especially ***Helianthoid Compositæ***, according to Dr. Asa Gray, who has enumerated the principal species in the 'American Journal of Science,' Series II., vol xxiii. p. 397.

The upper portion of the material constituting the superficial covering of the prairie is always finely comminuted, and usually has few loose boulders or fragments of rock scattered through it, although they sometimes lie upon the surface in isolated groups, or singly. Upon the great prairies in Central Iowa, one may frequently travel over a large extent of surface without seeing a single stone, not even so much as the smallest pebble. In the swales, and in some of the bottom lands, especially in the southern part of the State, the rich black vegetable mould is very deep, but on the prairies it is usually from one to two feet. The subsoil is almost invariably a quite argillaceous loam, and there is a gradual passage downwards into a material in which, though containing sandy portions and occasional pebbles, the argillaceous element greatly predominates.

The material of the superficial covering of the prairie has evidently not been transported to any great distance. It bears the marks of having had its origin chiefly in the decomposition of the rocks which underlie it, and in fact, the prairies are exclusively confined to regions underlaid by soft sedimentary strata, especially shales and impure limestones. It would be difficult to imagine, Mr. Hall remarks, a prairie soil existing on crystalline rocks.

After describing the prairies, Mr. Hall proceeds to discuss, as follows, the difficult and contested problem of their origin, and of the cause of the absence of trees over so extensive a region:—

"The idea is very extensively entertained, throughout the west, that the prairies were once covered with timber; but that this has been destroyed by the fires which the Indians have been in the habit of starting in the dry grass, and which sweep over a vast extent of surface every autumn. A few considerations will show that this theory is entirely untenable.

"In the first place, the prairies have been in existence at least as far back as we have any knowledge of the country; since the first explorers of the west described them just as they now are. There may be limited areas once covered with woods, and now bare; but, in general, the prairie region occupies the same surface which it did when first visited by the white man.

"But, again, the prairies are limited to a peculiar region, one marked by certain characteristic topographical and geological features, and they are by no means distributed about wherever the Indians have roamed and used fire. Had the frequent occurrence of fires in the woods been the means of removing the timber and covering the soil with a dense growth of grass, there is no reason why prairies should not exist in the eastern and middle states as well as in the western. The whole northern portion of the United States was once inhabited by tribes differing but little from each other in their manner of living.

"Again, were the prairies formerly covered by forest trees we should probably now find some remains of them buried beneath the soil, or other indications of their having formerly existed. Such is not the case, for the occurrence of fragments of wood beneath the prairie surface is quite rare; and when they are found, it is in such a position as to show that they have been removed to some distance from their place of growth.

"It has been maintained by some, that the want of sufficient moisture in the air or soil was the cause of the absence of forests in the north-west; and it is indeed true that the prairie region does continue westward, and become merged in the arid plains which extend along the base of the Rocky Mountains, where the extreme dryness is undoubtedly the principal obstacle to the growth of anything but a few shrubs, peculiarly adapted to the conditions of the climate and soil which prevail in that region. This, however, cannot be the case in the region east of the Mississippi and near Lake Michigan, where the prairies occupy so large a surface; since the results of meteorological observations show no lack of moisture in that district, the annual precipitation being fully equal to what it is in the well-wooded country farther east in the same latitude. Besides, the growth of forest trees is rich and abundant all through the prairie region, under certain conditions of soil and position, showing that their range is not limited by any general climatological cause.

"Taking into consideration all the circumstances under which the peculiar vegetation of the prairie occurs, we are disposed to consider the nature of the soil as the prime cause of the absence of forests and the predominance of the grasses over this widely extended region. And although chemical composition may not be without influence in bringing about this result, which is a question for farther investigation, and one worthy of careful examination, yet we conceive that the extreme fineness of the particles of which the prairie soil is composed is probably the principal reason why it is better adapted to the growth of its peculiar vegetation, than to the development of forests. It cannot fail to strike the careful observer that where the prairie occupies the surface, the soil and superficial material have been so finely comminuted as to be almost in the state of an impalpable powder. This is due partly to the peculiar nature of the underlying rocks and the facility with which they undergo complete decomposition, and partly to the mechanical causes which have acted during and since the accumulation of the sedimentary matter forming the prairie soil.

"If we go to a thickly-wooded region, like that of the northern peninsula of Michigan, and examine those portions of the surface which have not been invaded by the forest, we shall observe that the beds of ancient lakes, which have been filled up by the slowest possible accumulation of detrital matter, and are now perfectly dry, remain as natural prairies, and are not trespassed on by the surrounding woods. We can conceive of no other reason for this than the extreme fineness of the soil which occupies these basins, and which is the natural result of the slow and quiet mode in which they have been filled up. The sides of these depressions, which were once lakes, slope very gradually upwards; and being covered with a thick growth of vegetation, the material brought into them must have been of the finest possible kind, as is proved to have been the case by examination. Consequently, when the former lake has become entirely filled up and raised above the level of overflow, we find it covered with a most luxuriant crop of grass, forming the natural meadows from which the first settlers are supplied with their winter store of fodder."

The philosophical geologist may with advantage compare this part of Mr. Hall's statement and reasoning with those of Mr. G. Poulett Scrope and Sir C. Lyell respecting the formation of the Limagne d'Auvergne, or valley of the Allier, which was once the largest of three or four freshwater lakes existing in the miocene or middle division of the Tertiary period, in the country which is now Central France. The deposition of the fine lacustrine sediment which constitutes the marls and a part of the limestone of the Limagne, in an age characterised by numerous extinct mammals and reptiles, offers a curious parallel to that of the corresponding sediment of the ancient American lakes, forming the soil of the prairie basins, as described by Mr. Hall, at a much later period of the earth's history, one which may be said almost to connect the present with the latest pre-historic era. Nothing can be more different than the present geographical configuration and aspect, and geological structure, of the two regions; but the illustration which the comparison affords of the identity of geological causes in all periods, is most interesting and instructive. It suggests also the inquiry whether evidence can be obtained that at any epoch in the process of filling up of the basins of the ancient lakes of Auvergne, and formation of similar lacustrine plains in other parts of the world, the *prairie* condition intervened. The discovery of organic remains indicating the former existence of the peculiar prairie soil and vegetation would of course afford that evidence. In North America itself it would be equally important to ascertain whether any pleiocene or pleistocene formations present similar evidence of ancient prairies. See Scrope's 'Geology and Extinct Volcanos of Central France,' ch. ii., and Hall's 'Report,' cited above.

"Applying these facts," Mr. Hall continues, "to the case of the prairies of larger dimensions farther south, we infer, on what seem to be reasonable grounds, that the whole region now occupied by the prairies of the north-west was once an immense lake, in whose basin sediment of almost impalpable fineness gradually accumulated: . . . . that this basin was drained by the elevation of the whole region; but, at first, so slowly, that the finer particles of the superficial deposits were not washed away, but allowed to remain where they were originally deposited. After the more elevated portions of the former basin had been laid bare, the drainage becoming concentrated in comparatively narrow channels, the current thus produced, aided perhaps by a more rapid rise of the region, acquired sufficient velocity to wear down through the finer material on the surface, wash away a portion of it altogether, and mix the rest so effectually with the underlying drift materials, or with abraded fragments of the rocks in place, as to give rise to a different character of soil in the valleys from that of the elevated land. This valley soil, being much less homogeneous in its composition and containing a larger proportion of coarse material than that of the uplands, seems to have been adapted to the growth of forest vegetation; and, in consequence of this, we find such localities covered with an abundant growth of timber.

"Wherever there has been a variation from the usual conditions of soil, on the prairie or in the river bottom, there is a corresponding change in the character of the vegetation. Thus, on the prairie, we sometimes meet with ridges of coarse material, apparently deposits of drift, on which, from some local cause, there has never been an accumulation of fine sediment: in such localities we invariably find a growth of timber. This is the origin of the groves scattered over the prairies, for whose isolated position and peculiar circumstances of growth we are unable to account in any other way.

"The condition of things in the river valleys themselves seems to add to the plausibility of this theory. In the district which we have more particularly examined, we have found that where the rivers have worn deep and comparatively narrow valleys bordered by precipitous bluffs, there is almost always a growth of forest; but where the valley widens out, and the bluffs become less conspicuous, indicating a less rapid erosion and currents of diminished strength, there deposition has taken place under circumstances favourable to the accumulation of a prairie soil, and the result has been the formation of the 'bottom prairie,' which becomes so important a feature of the valleys of the Mississippi and Missouri below the limits of Iowa. Where these bottom prairies have become, by any recent change in the course of the river currents, covered with coarser materials, a growth of forest trees may be observed springing up, and indicating by their rapid development the presence of a congenial soil."

Llanos.—The whole interior of South America, from the mountains of Caracas on the north to the Straits of Magalhaens on the south, is divided by comparatively low transverse ridges, running east and west into three great basins; that of the Orinoco on the north, that of the Amazon or Marañon in the centre, and that of the La Plata on the south. The first comprises the llanos, vast plains occupying a surface of 260,000 square miles. They may be divided into two principal portions: the first, beginning at the mouths of the Orinoco, extends westward as far as the Andes of New Granada, being bounded on the north by the Caracas, and on the south by the mountainous group of Parimé and the Rio Apure, an affluent of the lower Orinoco. The other portion of the llanos, which is twice as extensive as the first, reaches from the Apure on the north to the Caqueta (an affluent of the Marañon) on the south: having the Andes on the west, and the sierra of Parimé and the Orinoco on the east. The inclination of these plains is to the east and south, and they are traversed by many streams, which, taking their rise from the eastern slope of the Andes, bear their tributary waters to the Orinoco. As the medium height of the llanos does not exceed 200 feet, the course of the rivers is very slow and often scarcely perceptible.

The chief characteristic of the llanos, says Humboldt, is the absolute want of hills and inequalities, the perfect level of every part of the soil. Often in the space of 270 square miles there is not an eminence of a foot high. This resemblance to the surface of the sea strikes the imagination most powerfully where the plains are altogether destitute of palm-trees, and where the mountains of the shore and of the Orinoco are so distant that they cannot be seen. This unvarying equality of surface reigns without interruption from the mouths of the Orinoco to the Villa de Aurore and Ospinos under a parallel of 540 miles in length, and from San Carlos to the Caqueta, on a meridian of 600 miles.

There are however, notwithstanding this uniformity of surface, two kinds of inequalities in the llanos. The first, called *brancos*, are horizontal banks of sandstone or limestone standing four or five feet higher than the rest of the plain, and sometimes many leagues in length. The second kind of inequality, called *mesa*, consists of convex eminences rising to the height of a few fathoms.

The llanos have different names in different parts: thus, from the Mouth of the Dragon, the llanos of Cumana, of Barcelona, and of Caracas or Venezuela, follow from east to west, when, turning southward from 8° N. lat., between the meridians of 67° 40′ and 70° 40′, we find the llanos of Varinas, Casuare, the Meta, Guaviare, Caguan, and Caqueta. All these are again subdivided.

The aspect of the llanos is somewhat dissimilar in different places; but the greatest difference depends upon the seasons. The local dissimilarity arises chiefly from the nature of the palm-trees scattered about, which vary in different places, and also from the greater or less abundance and variety of the dicotyledonous plants which are intermixed with the grasses, the height of which latter is also very unequal, being sometimes only a few inches at a distance from the watercourses, and rising to a height of four feet in their vicinity. In this high grass the jaguar, or American tiger, lurks to spring upon the mules and horses that cross the plain. But the season of drought or of rain entirely change the aspect of the greater part of the llanos. In the rainy season, says Humboldt, the llanos display a beautiful verdure, but in the time of great drought they assume the aspect of a desert. The grass is then reduced to powder, the earth cracks, the alligators and great serpents remain buried in the dried mud, till awakened from their long lethargy by the first showers of spring. These phenomena are observed on barren tracts of fifty or sixty leagues in length where the llanos are not traversed by rivers.

The principal and almost the only trees of the llanos are different varieties of palms. The *Corypha tectorum*, or Palma de Cobija, solitary or in clumps, rises here and there as a landmark through these trackless plains. It is chiefly found in the llanos of Caracas from Mesa de Peja, as far as Guayaval. Farther north and north-west, near Guavare and San Carlos, its place is taken by another species of the same genus. Other palm-trees appear to the south of Guayaval, especially the *Píritu*, with pinnate leaves, and the *Murichi*, whose beautiful verdure, at the period of the greatest drought, contrasts with the mournful aspect of the grey and dusty leaves of the cobija. Two or three other species of trees besides palms are also found in the llanos, and it is round these clumps that the llanos are the most fertile.

The great wealth of the llanos consists in the numerous herds which they feed. The first horned cattle were let loose in these extentive pastures by Christoval Rodriguez, about the year 1548, since which time they have increased to almost countless numbers. About 98,000 head of cattle are said to wander in the pastures round Calaboza. But, according to M. Depons, there are, from the mouths of the Orinoco to the lake of Maracaybo, 1,200,000 oxen, 180,000 horses, and 90,000 mules, the annual produce of which herds is estimated at about 5,000,000 francs. But these estimates were made many years since, and are scarcely applicable to the present time.

All the parts of the llanos are not equally favourable for the breeding of mules and oxen; but in some of those places, where the herds are less numerous, the pastures are so fertile as to furnish meat of an excellent quality for provisioning the coast.

The horses of the llanos are not very large, but are descended from a fine Spanish breed. Deer are natives of these plains.

The greatest curiosity of the llanos are the gymnoti, or electrical eels, which live in the pools as well as in the rivers of this part of South America.

We may also mention, as distinguishing the llanos from the pampas, and from the plains of North America, the Sahara, and the steppes of Asia, the total absence of any formation of chloride of sodium or common salt.

Pampas, from an Indian word, which, in the Quichua language, signifies properly a flat, is the name given to extensive plains in the southern and central parts of South America. Those which lie to the south and north-west of Buenos Ayres are called, the former the Pampas of Buenos Ayres, or simply the Pampas, and the latter the Pampas of Cordova. The plains to the south of the province of Chiquitos bear the name of the Pampas de Huanacos. There is also one more to the north, between the river Beni and the river Marmore, a tributary of the Madeira; and lastly, to the north between Huallaga and the Ucayal there is another, called the Pampas del Sacramento.

The Pampas of Buenos Ayres are bordered on the west by the forests which lie along the base of the Andes of Chile; on the east by the Atlantic; on the south by the Rio Negro and Patagonia, the interior of which, though little known, seems to be of the same nature with the pampa itself; and on the north-east by the Rio de la Plata. In the direction due north the pampa narrows between the Parana and a ridge coming from the Andes, called the Sierra de Cordova.

This region, reckoning to the foot of the mountains on the west, occupies a surface of about 315,000 square miles. This plain has no general slope, or rather it slopes so gently towards the east, that the slightest inequalities, together with the absorbing nature of the soil and the great evaporation, are sufficient to arrest the course of the waters; so that, with the exception of the rivers Colorado and Negro, which come from the Cordilleras, and which traverse the southern part of the pampas, and the Salado, a small stream which flows into the Rio de la Plata at its mouth, the pampas have no running waters, but, instead of them, a great many shallow pools, of which the water is often brackish. There is one at about 450 miles from Buenos Ayres, in the direction west-south-west, always filled with salt, from which the city of Buenos Ayres was yearly supplied before the port was thrown open to foreigners. The southern part of the pampas is sandy, with patches of saline plants and stunted trees; the northern parts are covered with grass, supplying food to large herds of cattle and wild horses, the descendants of those first introduced by the Spaniards. It has been said that several million head of cattle and about half as many horses feed on the pampas of Buenos Ayres. There are also wild beasts.

This plain is traversed by a road which leads from Buenos Ayres to Chile, along which the traveller meets with huts, which form stations, distant from each other about seven or eight leagues. The journey may be made on horseback or in a carriage, but it is sometimes dangerous, on account of the Indians.

The pampa of Cordova extends from the right bank of the lower Parana to the Sierra de Cordova at the west. On the north it joins the sandy plains or *travesia* of Santiago del Estero.

This pampa resembles that already described in all things, excepting being traversed by a greater number of streams. All these streams, however, with the exception of the Rio Salado, which falls into the Parana, lose themselves in the sands, or end in marshes and lakes without issue, and which in the country are called *Lagunas*. Such is particularly the case with the Rio Dulce, which, rising in a fertile valley on the eastern slope of one of the lateral chains of the Andes, passes by S. Miguel de Tucuman and Santiago, and finally empties itself into the Lagunas de las Porongos; the same is also the case with the Rio Primero, on which is situated Cordova, the best of all the towns of Tucuman, and where the Jesuits had formerly a celebrated university.

Throughout the whole of the country between the Parana and the mountains to the west, from Chaco on the north to the extreme southern extremity of the Pampa of Buenos Ayres, there is neither river, lake, nor well that is not brackish, saline, or alkaline. Even the Pilcomayo and the Vermejo partake of this saltness; and Azara assures us that he has seen in lagunas, dried up by the heat, a layer of Epsom salts above three inches in thickness. Nitron, sulphate of soda, and glauberite also occur in the lagunas.

The inhabitants of the fertile valleys lying to the west and north of the plains of Tucuman, similar in some respects to Little Bucharia, rich in their flocks, without ambition, and without care, close the day in rural amusements worthy of being sung by Theocritus and Virgil. It is nevertheless true that there are spaces of many square leagues in extent condemned to absolute sterility. The traveller may pass for days together over sands and stones, between which there spring up here and there some saline plants, without meeting with any other objects than a few isolated huts on the borders of some brackish stream; these barren districts are generally designated by the term *travesia*.

Pampa of Huanacos.—Leaving the pampa of Cordova on the south, and travelling through forests swarming with bees, which extend beyond the Rio Dulce and the Salado, we enter on the territory of the Abipones, a race of very warlike Indians; after which, crossing the Rio Vermejo, we gain the plains of the Gran Chaco, occupied by more or less savage indigenous tribes. This region is traversed by the Rio Pilcomayo, which, passing near the mines of Potosi, falls into the Paraguay below the city of Assumption. To the north lies the Pampa de Huanacos, adjoining the province of Chiquitos, bounded on the east by the great laguna of Xarayes, through which passes the frontier of Brazil; on the west by the heights of Santa Cruz de Sierra, and on the north by the forests of the province of Moxos and the sandy plateau called Campos Parexis.

Pampa de Moxos is on the north of the province of Moxos, between the rivers Beni and Marmoré; and between the junction of this latter and the Guapore, another source of the Madeira, are other pampas of considerable extent.

Pampa del Sacramento.—This pampa is situated on the north-west of Cuzco. It differs from the other pampas in having a more tropical vegetation, and in its soil not being saline. It occupies a surface of from 54,000 to 63,000 square miles.

Such are the principal pampas of South America; and, if we include a part of Patagonia as being of the same nature with the pampas, we shall have, without reckoning the pampas of Moxos and Sacramento, and a number of spots of similar character but less extent, an almost uninterrupted band, extending from the Campos Parexis, in latitude 15° S., to the bay of St. George in 45°, or about 2800 geographical miles long and 300 wide, or a surface of 840,000 square miles of plain, partly sand, and partly marshy and saline, and producing hardly anything but pasture and a few stunted trees. Humboldt estimates the whole of the pampas of Rio de la Plata and Patagonia at 135,200 square leagues of 20 to the degree.

The *Selvas*, or forest-covered plain of the Marañon.—Independent of the vast forests which cover great part of the plains of North America, particularly on the east of the Mississippi, there is the immense plain of the Marañon in South America, extending over a surface of 2,340,000 square miles, of which about 719,000 are covered with primeval forests, the rest of the space being occupied by the waters, and by open patches of a character similar to the llanos and savannas, though little known. We merely mention this region here as one of the most extensive continuous plains in the world.

If the great plains we have described owe their peculiar character to climate and situation, a very little reflection will suffice to show the immense influence which they in their turn must exercise over the climate of the regions contiguous to them, and the great modifications they must effect on mere solar temperature. Indeed the curves of the isothermal lines sufficiently prove that the several climates of the earth depend on the joint action of solar radiation, and the magnitude, distribution, conformation, soil, and productions of the solid parts of the globe, and the extent and relative position of the great bodies of water by which they are surrounded. Nor have the vast plains of Asia and America performed a less important part in the moral history of mankind, whether as having favoured or opposed the emigrations of nations and the progress of civilisation.

PLAN. This word (which is the same as Plane) means a representation of a plane section of any building, country, &c. Usually it is to the horizontal section that the term is applied, the words section or elevation being used to signify the vertical plans. A map is not properly a plan, but a PROJECTION, unless the country represented be perfectly level: nevertheless the term is commonly applied to maps of very small portions of a country, as an estate or a town.

PLANE, PLANE-ANGLE. [STRAIGHT LINE AND PLANE.]

PLANE, INCLINED. [INCLINED PLANE.]

PLANE OF POLARIZATION. [POLARIZATION.]

PLANET (ἀστὴρ πλανήτης, a wandering star), PLANETARY

THEORY, MOTIONS, PERTURBATIONS, INEQUALITY, &c. The term planet was first used as one of distinction between the stars which preserve their places, or seem to do so, and those which have a sensible motion, and, as is now known, about the sun. The etymology would oblige us to include comets—many of the stars, which have small motions of their own, or proper motions, as they are called—all those double stars which revolve about each other—and all the satellites which revolve about other planets. As discovery proceeds, it is likely that every body in the universe will be found to be planetary. The word however has changed its meaning, and is used to stand for a heavenly body which makes successive revolutions about our sun. It thus includes—the old planets, Mercury, Venus, Mars, Jupiter, Saturn (excluding the sun and the moon, the most easily discovered planets of all)—the planet of Copernicus and Galileo, on which we live—the new planets or Asteroids, of which there are now (November, 1860) sixty-two; and the periodic comets of Halley, Encke, Biela, Brorsen, D'Arrest, and probably many others.

The plan of this work leaves us little to say under so general a term as Planet, and that little consists mostly of references, and explanations of isolated points. The order of discoveries connected with the subject, so far as it is matter of history, must be looked for under Astronomy. It is impossible to separate the history of one part of astronomy from that of another: the fixed stars, on which all celestial measurements depend, must accompany the planets in every account of the latter; the mathematical and physical considerations which give rise to our power of predicting the motions and places of the planets, apply equally to those of the moon and comets.

By a Planetary Theory was once meant any hypothesis which serves to explain the motions of a planet, as actually perceived. Thus there was one theory of Mercury, another of Venus, &c., each (without connection with the rest) expounding the nature and magnitude of all the suppositions which must be superadded to that of the simple circular motion round the sun, in order to enable the theorist to predict the planet's place at any given future time. At present, by the theory of a planet is meant the deduction of its motion from the theory of gravitation. Given the places of all the bodies of the solar system at any one moment, together with their velocities and the directions of their motions, the assumptions of the theory of gravitation are found sufficient to deduce tables which almost rival observation itself in the accuracy with which predictions can be made; for an instance, see Moon. When tables are constructed with such fundamental data only, they are called *theoretical*: but if some of those details which should have been deduced from the theory of gravitation have been deduced from observation, the tables are then partly *empirical*. For the treatment of the theory of gravitation as a question of physics, see Attraction: for the deduction of the character of the main inequalities of the planetary motions, and most points connected with the detailed results of that theory, see Gravitation: for the results which are particularly connected with the secular inequalities, and the reasons which we have to infer the permanence of the whole system, unless acted on by some new and external cause, see Solar System. See also the general considerations under the word Theory.

The Planetary Theory, it must be remembered, in the sense in which those words are now understood, explains only the motions of the planets round the sun. A spectator situated on the last-named body would find it sufficient to predict the place among the stars, of every planet at every time: or a terrestrial astronomer might assign by it the places of the planets as seen from the sun, which are called *heliocentric* places. But our own circumstances, as being ourselves revolving about the sun, cause the apparent planetary motions to vary most materially from the real ones, and the *geocentric* places (or places as seen from the earth) to differ literally *toto cœlo* from the heliocentric places. Thus, as seen from the sun, a planet moves from west to east, always: as seen from the earth, it sometimes moves from east to west. As to this point, the circumstances of our day are, in regard to the astronomical education of the world at large, a complete reversal of those which preceded the time of Newton. Formerly, the apparent motions were well known to those who knew anything; the real motions were matter of dispute: now, every well educated boy of fourteen has a very good notion of the real motions, while few, except astronomers, could distinctly explain the apparent ones, and maps of them are quite out of date. To explain these motions here would require us to introduce the contents of another article; the whole of what is necessary on this point will be found in Trochoidal Curves, the preliminary considerations being found under Motion.

The places of the principal planets are usually given in the almanacs, at intervals of several days, in a manner which is sufficient to find them in the heavens. In the 'Nautical Almanac' is to be found a Greenwich meridian ephemeris of every planet for every day in the year, in which the places are predicted to the smallest quantities, so that the reduced observation of any one day affords an immediate comparison of the theoretical tables with the fact.

PLANETARIUM. [Orrery.]

PLANING MACHINERY. Of late years the increase in the price of hand labour, and the necessity for securing mathematical accuracy in the surfaces of contact of the parts of machinery, have led to the application of other machinery to the preparation of the surfaces of wood, of stone, and of iron-work. The nature of the various materials has led to modifications of the tools employed, as might naturally have been expected; and it is worthy of remark that the application of machinery to this purpose has been much more successful with the more apparently intractable and hard materials, stone and iron, than it has been with the softer one, wood. Generally speaking, the tools used for planing wood, or iron, are fixed at a certain height, but are able to reverse the direction of their points; and the surfaces to be operated upon may be moved horizontally under the tools, so as to be attacked in their alternate motion, or only in one direction when the cutting tools are not susceptible of being reversed. In wood planing machinery the majority of the tools hitherto used in England have a rotary motion; and from this fact, and from the tendency of the wood to tear up, as the workmen say, it is necessary to finish the best class of joiner's work by hand labour. It may be also stated that until the introduction of planing machinery for iron, it was almost impossible to obtain a large and perfectly level surface on a plate of that metal; so that in fact this machine has been one of the most important agents in the advance of the arts connected in any way with the use of iron. The success of the application of machinery to the dressing of stone, or of wood, depends, however, solely upon the value of hand labour; and its introduction becomes a mere question of local economy, whence its more general use in America.

In the iron planing machinery there is a large bed or plate connected with the driving machinery in such a manner as to allow the bed to move alternately to and fro in a horizontal direction; and the tool or chisel is fixed in a carrier, so as either to reverse the position of its point when the bed has reached the end of its course, or it is raised on a horizontal pin so as to allow of its being lifted by the projections of the surface operated upon, and thus only to work whilst the bed is travelling in one direction. The distance between the bed and the carrier is regulated by a screw; and the width of the face of the tool is varied according to the greater or lesser quantity of iron to be removed, the finishing tool being wider than the roughing point. A slight burr is left on each side of the path of the tool, which is removed subsequently if a perfectly smooth face should be required. Almost all the tool makers of the present day manufacture these beautiful machines; but those made by Mr. Whitworth are certainly amongst the best, even if they be not the very best, of their class.

Mr. Hunter took out, some years since, a patent for a modification of the iron planing machinery, which has been applied with such remarkable success by the late Mr. L. F. Carnegie, in his flag stone quarries near Arbroath, that it must remain a matter of surprise that the use of the machine has not been more generally diffused. In Mr. Hunter's stone planing machine the bed moves under a chisel, of a width of face varying inversely with the amount to be removed, as in the case of iron planing engines, and the slight burrs are worked down by hand. The American stone planing machines seem to consist for the most part of rotary cutters of chilled cast iron which wear away by friction the surfaces exposed to their action.

The ordinary descriptions of wood planing machines consist of cutters, or steel plates, working with a rotary motion; but, as was before stated, they do not leave the finished surface in the state required for good work. The best American machines of this kind, however, have cutters like an ordinary plane iron, screwed to a carrier able to be adjusted over the board to be operated upon by means of a screw. In front of each cutter is placed a loose bar as near to the knife as possible, for the purpose of keeping the grain of the wood perfectly close immediately before the knife. For the best description of joiner's work the wood thus planed requires to be finished off with the smoothing plane, as in the case of the wood prepared by the ordinary jack, or trying planes used in ordinary hand labour. In the latter case the rough work is done by the jack plane; it is carried to a higher point by the use of the trying plane, and is finished by the smoothing plane.

PLANISPHERE. This term originally stood for any representation of all or part of the sphere on a plane; it is now out of use, at least in that sense. It has partially however been retained (and it would be desirable that this meaning should become fixed and general) to signify any contrivance in which plane surfaces moving on one another fulfil any of the uses of a celestial globe.

The instrument which we proceed to describe is one which when made correctly, at or near a given latitude, is, for ordinary uses, that is, for finding the position of the heavens at any one moment, much more easily used than the celestial globe, and very much less expensive. A circular disc of pasteboard, on which the stars visible in our latitude are laid down, turns on a second disc, round which are the days of the year on one circle, and the hours of the day on another. A third and hollow disc turns upon the same pivot, the hollow part being so cut that the portion of the heavens which it shows is precisely that which is visible at one time in the latitude of the instrument: the points of the compass are marked round the rim of the hollow disc, or of the horizon. The effect is, that by setting the disc which contains the stars to the day of the year, and the hollow disc to the hour of the day, the part of the heavens visible at that day and hour is distinctly shown. The time at which any star rises, culminates, and sets can be immediately found within a minute.

PLANTING and PLANTATIONS. Planting is the operation of placing in the soil the roots of a plant which has been previously removed; and the preservation of the roots is the first thing to be attended to. It should be kept in mind that the *spongioles*, or delicate extremities of the fibres, are the parts by which the chief supply of food from the earth is absorbed by the plant. Their tissue being tender and almost naked, they are very susceptible of injuries from mechanical action; and being adapted for performing their functions in a humid medium, they readily suffer from being kept for any length of time exposed to free air and drought. In taking up the plants, therefore, the roots should be loosened in such a manner as to receive the least possible violence in the operation. Plants in pots can be shifted from one place to another without exhibiting symptoms of deranged functions; and if it were possible to preserve the spongioles of a large tree as entire as those of a plant in a pot, the same successful result would follow. But as it is next to impossible to do this, we can only attempt to preserve them as far as circumstances will permit. If the tree be large, a trench should be opened beyond the extremities of the roots, of sufficient width and depth to allow the process of undermining to be freely carried on. The roots should be gradually set at liberty by a round-pronged fork, the prongs tapering so as to be easily inserted, yet not by any means so sharp as to prick the roots. As the fork is being used, the soil from among the roots will fall into the open trench; but as it accumulates there it must be cleared away, and at the same time the portion of roots set at liberty will require to be slightly tied together with pieces of matting, and, if necessary, supported by temporary stakes, or held to one side by an assistant, whilst the planter proceeds in liberating others. If there be, as is frequently the case, a tap-root extending to a much greater depth than the other roots, and if the latter have been carefully preserved during the operation, the tap-root may be dispensed with, for it could only be raised in a mutilated state, owing to the great solidity of the earth at such a depth.

Although it is very desirable to preserve the greatest possible quantity of sound roots, yet all that are bruised or lacerated should be cleanly amputated up to the sound parts. Cross-roots are apt to gall the others when they become large, and therefore the sooner they are removed the better. When the plants are young, and in the course of being occasionally removed in a nursing state, all irregularities in the roots should be corrected, which can then be done with comparatively little injury, as the roots of young plants bear a greater proportion to the top than seems to be the case at a more advanced period of growth, and the loss of any of them is consequently felt less. In the early stage of rearing trees, while the proportion of roots predominates, it may be found advisable in various cases to shorten not only the tap-root, as above mentioned, but also judiciously some of the other strong roots, in order that subdivisions of a more fibrous nature may be produced, and a number of rootlets substituted for large root-branches. Even in the case of large trees this principle has been acted upon for centuries, and latterly it has been strongly advocated and put in practice for the purpose of producing immediate effect in park or landscape scenery. A trench is cut out round the tree, and the roots shortened wherever they happen to traverse this trench, so as to leave it quite clear. This being done, the trench is filled up, either with its own excavated soil, or, in very particular cases, with fresh soil. The tree has still a sufficient number of undisturbed roots to keep it alive; and in fact it ought not to be merely kept alive, but as many roots should be left as will ensure its continuing in a healthy though not a vigorous state of growth. In the course of a year or two after this operation has been performed, a number of young roots will have been protruded from the various amputations into the loosened soil of the trench; and partly from the possibility of preserving these roots, and partly from the top becoming habituated to a more limited supply of food, the tree feels comparatively little the change consequent on transplantation.

Roots may be produced of a proper description for planting by the adoption of such means as the above, and if care be taken they will suffer little from the operation of removal. Still they may be seriously injured from exposure to air, and more especially to drying winds, frost, and even to wet. To be covered in the soil is the natural condition of the roots of most vegetable productions, and therefore endeavours should be made to place them in such a condition with the least possible delay; or at all events, if circumstances render delay unavoidable, such means should be adopted as will preserve them in a state of moisture similar to that which they have in the soil. It is however necessary to observe, that when the tops are closely packed up and evaporation from them prevented, the roots should be kept rather dry than otherwise; for under such circumstances, damp is found to be much more frequently destructive than a little dryness.

Though the preparatory steps to planting, as regards roots and their preservation, may be properly taken, yet, if the operation be not performed at the proper season, success will not be complete. It is true that instances may be adduced of planting being done at the very opposite season to that which is here recommended as the best; but such cases are only examples of what may be done by extraordinary care in adopting artificial means so as to imitate more natural circumstances. It is a well-known fact that plants are subject to a process of evaporation from all the parts which are exposed to the atmosphere, provided the latter is not in a state of saturation. The source from whence this evaporation is supplied is the moisture of the soil, and the roots are the media by which it is collected and transmitted to the stem, branches, and leaves. If the expenditure be greater than the supply of moisture, the plant will begin to suffer; if the disparity be great and continued, a degree of desiccation will be occasioned sufficient to deprive the vegetable tissue of that moisture which constitutes the medium of intercommunication between the different cells; organisation is destroyed; the chain which connected it with vitality is broken, and incapable of being re-united by any mechanical means.

A much greater amount of evaporation takes place from a given surface in some species than in others; but the amount as regards plants of the same species, all other circumstances being the same, is in proportion to the extent of surface which the respective individuals possess. The leaves of a lime-tree may have a surface equal to thirty times that of the stem, branches, and twigs which produce them, and consequently the demand on the roots for the supply of evaporation will be thirty times greater when in leaf than when the branches are naked. Instances might be adduced in which this difference would even be exceeded; but if, on the contrary, it were found considerably less, still there would be sufficient evidence of the impropriety of moving plants when in leaf; and it may be here remarked, that young leaves admit of the fluids being more rapidly evaporated than old ones.

The month of December is that in which the condition of the air with regard to moisture approaches nearest to that of complete saturation, and next in this respect is January, which is also the coldest. It might therefore be concluded that these months are the best for planting, more especially as they are the most opposite in character to June and July, which, from their being the hottest and driest, are found to be the worst. But November is also moist; and although the temperature of the season has not then reached its minimum, yet the foliage, accustomed to exercise its functions under a summer heat, can no longer perform them under a reduction of temperature, which, though not the lowest, is comparatively low as regards summer productions. The leaves in consequence lose their connection with the roots; the earth still retains considerable warmth; and although the absence of leaves in deciduous trees, and perhaps the inactivity of those of evergreens, may prevent the formation of wood, except in the most limited degree, yet the buds, whilst they are themselves increased in volume, maintain a corresponding action in the roots, sufficient in many instances to form fresh spongioles before winter, a process which is favoured by the soil being warmer than the atmosphere. Should circumstances occur to prevent the actual protrusion of cellular substance in the form of spongioles, still an accumulation of it will be taking place, ready to burst forth in spring. On this account therefore, although December, January, and February are sufficiently moist, yet November, or as soon as the leaves have fallen, is the preferable season for planting. There may be some exceptions, as in the case of very wet soils, where the plants, if not firmly rooted, are liable to be thrown out during winter, owing to which spring planting would be more proper. But under ordinary circumstances all deciduous trees will succeed best at the period above indicated. Such species as push forth their buds early ought certainly to be planted in autumn. Many of the coniferous tribe will succeed well if planted soon after they have made their summer's growth: the earth is then warm, and the plants make roots very promptly. Some species of this interesting order of trees require to be planted either before winter, so as to have sufficient time to strike root, or immediately before their buds begin to burst in the spring. These species of trees are injuriously affected by exposure to dry cold winds, even when their roots are undisturbed by removal; but if planted at a season when several months must elapse before any perfect action can commence, the tops are apt to become dried up in the interval. It appears that if their juices become inspissated to a certain extent, they never again become liquified, probably owing to their resinous nature.

The watering of newly planted trees ought to be attended to. The supply in the first instance should be copious, in order to wash the earth into the cavities among the roots. Some err in keeping the roots of newly planted trees constantly soaked with water, as if they were those of bog-plants, for which only such treatment is proper. In watering, consideration should always be had to the nature of the plant, to which, if it delight in dry soils, no more water should be artificially applied than is necessary to moisten it as much as the soil in which the species grows naturally, and at a time when shoots and leaves are abundantly produced. When watering is performed, it should be done thoroughly, so as to reach the lowest portions of the root. In the case of plants being much dried from long carriage or other causes, the supply on first planting should be very moderate. The tops however should be frequently syringed, in order to moisten the bark and prevent its absorbing the organisable matter which descends towards the root by the inner bark. The flow must be extremely weak under such circumstances; but if it can be preserved from the effects of drought till it reach the extremities of the roots, the formation of fresh spongioles will immediately commence, and the tree may then be pronounced out of danger.

The manner of performing the operation of planting may be reduced to one general principle, that of placing the roots in the soil so as to imitate as closely as possible the position which they occupy when growing wild and uncontrolled. Plants indeed may be instanced whose roots have been observed in one situation penetrating to the depth of four or five feet; or in another, creeping along the surface, amongst stones, or into the crevices of rocks, with scarcely soil to cover them, as for example in the vine. But although roots can usually accommodate themselves to that position which the nature of the situation renders it alone possible for them to occupy, yet there can be no doubt that in all cases the extremities of the roots should be lower than where they diverge from the stem, a rule which, however self-evident it may be, is frequently violated in practice by making a basin-shaped hole, deepest in the middle, in which the roots are either doubled or have their extremities tending upwards on the sloping sides of the cavity.

The excavation for the reception of the roots of a plant should be considerably larger than those roots will traverse when extended at the time of planting. It should be as wide at bottom as at top. The bottom should be more or less convex, and the depth such as to admit of the roots being covered to the extent observed in undisturbed seedling plants of the same species; that is to say, the upper part of the root should only be just covered. The lower roots should be regularly disposed over the convex bottom of the excavation, and carefully strewed with some of the finer portion of soil, over which the other roots may be spread. More soil should then be carefully rather than forcibly introduced. There should be no vacant spaces left, except those of so minute a description that they will be readily filled up by the finer particles of earth washed down by a plentiful watering. This watering should be given when the soil is nearly all filled in; and after the water has subsided so as not to stand above the surface, the latter should be covered with the remaining portion of soil. Except in very loose or light soils, this method will supersede the necessity of the hard beating and treading in to which the roots of trees are very generally subjected. The latter practice is now however being laid aside by many, from a conviction of its injurious effects. It is also necessary to remark that a plant should be placed, before the introduction of the soil, exactly as it is intended it should stand; and it should not be pulled from side to side for the purpose of shaking the earth amongst the roots. If the tree be drawn to one side, the fibres of the root will also be drawn towards the same side; but they are of course too flexible to force their way back when the tree is drawn in a contrary direction, and they must therefore become more or less doubled. Nor should the soil be thrown *against* the fibres whilst the roots are being covered; it should be made fine, and either shaken from the spade so as to fall perpendicularly among the roots, or scattered by a force impelling it in the direction of the fibres, which will be in general from the stem towards the extremities, or from the centre to the circumference.

The principles here stated are applicable to the planting of large as well as small trees, and in fact to any terrestrial species of plant. There are, however, many modifications in practice, some of which may be noticed as proper under certain circumstances, and others as only to be condemned under any circumstances whatever.

Small plants are very frequently inserted by the *dibber*, a cylindrical piece of wood, shod with iron and tapering to a point. This is thrust into the soil, and in the hole formed by this means the roots of the plant are introduced, and a portion of soil pressed towards them by a second stroke of the dibber. It is evident, however, that by this procedure the roots cannot be in the most natural position; they are in fact the very reverse of being spread out to the best advantage. In the case of very valuable species the spade or planting-trowel is used in preference to the dibber. The latter has nothing to recommend it on the score of good principles in planting; the expedition with which it can be employed is all that can be said in its favour.

Besides the spade and dibber, various other implements are used in planting, such as the *diamond dibber*, a pointed plate of steel with a short iron handle; a *mattock*, used in stony soils; and some others, adapted according to circumstances. In all cases, however, where the spade can be used, it is undoubtedly the best instrument. If the soil be unfit for allowing the use of the spade, it should be rendered fit previously; and if some time be lost and expense incurred by using it instead of smaller and more expeditious, but at the same time more cramping implements as regards the roots, the difference will certainly be ultimately in favour of a proper disposition of the roots by means of the spade.

With regard to the preparation of the soil for plantations, it is found that trenching the ground is attended with profit where it is practised for the purpose of rearing wood for fuel and small timber. This mode of preparation ought likewise to be adopted where trees are intended to be planted for ornament or for shelter. It has not been generally attempted in the case of extensive plantations of heath or rugged mountain-land. It may, however, be affirmed without hesitation that great advantages would be derived from the operation being more extensively performed. Something more than merely burying the roots of hard-wooded plants is thought necessary, and accordingly *pits* are made. It is scarcely necessary to observe that if these are not of considerable size, the direct progress of the roots is soon obstructed. The time required to form these pits as they ought to be, would be sufficient to regularly trench double their area. The expense of trenching the intermediate spaces will be compensated by the greater return derived from the nurse plants, such as larch, when they come to be removed.

Plantations are generally planted thick in the first instance, and with various species of trees. Larch, Scotch fir or pine, mountain ash, &c., are interspersed amongst the hard wood for shelter, or as nurses. Laburnum is also useful for preserving the other sorts from the depredations of hares, as they prefer the laburnum to every other bark. Nurses are generally left till they are fit for various purposes for which small timber is applicable. They should be planted closer to each other than to the principal trees intended to constitute the more permanent part of the plantation.

After all the care of the planter and the skill with which the operation of removal may have been effected, much of the success of a plantation depends on the proper adaptation of species to the soils and situations most suitable to them.

The following remarks upon some of the timber-trees principally cultivated may be useful.

The oak, *Quercus robur*, and *Q. sessiliflora*, prefers strong or even clayey loam; any soil not wet or chalky.

Beech, *Fagus sylvatica*, calcareous soils, gravelly or sandy loam; dislikes stiff clay.

Elm, *Ulmus campestris*, *U. glabra*, *U. montana*, attains, near the banks of rivers, a large size; thrives in most soils.

Ash, *Fraxinus excelsior*, prefers a dry subsoil; dislikes stiff clay.

Plane, *Platanus orientalis*, rich warm soil, tolerably moist, but not retentive.

Sycamore, *Acer pseudo-Platanus*, *A. platanoides*, best in moist deep soil, but will thrive in others not too stiff; withstands the sea-breeze.

Chestnut, *Castanea vesca*, deep sandy loam.

Walnut, *Juglans regia*, deep loam with a pervious subsoil; dislikes strong clays.

Hickory, *Carya alba*, similar soil to that required by the walnut.

Acacia, or locust-tree, *Robinia pseud-Acacia*, sandy loam; a sheltered situation; cannot bear storms.

Birch, *Betula alba*, forms best timber on dry sandy or gravelly soil.

Laburnum, *Cytisus alpinus*, any soil not too wet.

White Bean, *Pyrus Aria*, any good soil, with a pervious subsoil dislikes wet clay.

Lime, *Tilia Europæa*, soft deep loam, in low rather moist situations.

Horse-Chestnut, *Æsculus Hippocastanum*, deep loam; not in exposed situations.

Poplar, *Populus alba*, *P. canescens*, *P. nigra*, *P. tremula*, *P. fastigiata*, *P. Græca*, *P. monilifera*. These thrive in almost any soil, but best in that which is deep and rather moist.

Mountain-Ash, *Pyrus Aucuparia*, any soil, wet clay excepted; adapted for high situations.

Alder, *Alnus glutinosa*, moist or even swampy soil.

Willow, *Salix*, of numerous species. Some thrive in rather dry soil, but all prefer moist.

Pine, *Pinus sylvestris*, *P. Laricio*, *P. Pinaster*, *P. Strobus*. The two first are adapted for thin, rocky, gravelly soils; they grow at a great elevation on the warmest sides of mountains, but better in mountain glens; they dislike stiff clay and deep strong loam, and, like all coniferous plants, they do not thrive on chalk. *P. Pinaster* and *P. Strobus* require a less exposed situation than the other two.

Spruce, *Abies excelsa*, *A. alba*, *A. rubra*, *A. nigra*, deep moist soil, in low situations; dislikes thin sandy soil and exposure.

Larch, *Abies Larix*, adapted for thin mountain land, or any soil of which the subsoil is not retentive, excepting, however, red sandstone or chalk, as above mentioned.

Cedar of Lebanon, *Abies Cedrus*, any tolerably good soil, rather deeper than for the larch, but a pervious subsoil, free from stagnant water.

Too close planting produces weak drawn-up timber, in consequence of the tops only receiving a due share of light. It is true that the most magnificent trees are found in those ancient forests that have never been sown, planted, or thinned by the hand of man. But at the same time it will not be denied, that wherever natural forests exist, the soil and situation must be exceedingly favourable for the species produced; and that although thousands sprung up more than could possibly find room to attain perfection, yet those only that were the most favourably circumstanced and most vigorous would continue; and when once their tops got completely above those of the general mass, the latter must have inevitably fallen into decay. There is no reason, however, to suppose that those which maintained their ground, and, favoured by propitious soil, became lofty specimens, would not have been benefited by the assistance of the axe to relieve them sooner from their rivals.

If, on the contrary, trees are planted at too great a distance from each other, they are inclined to ramify into large limbs and spreading tops, with a stem short but much thicker than where the space admits of less expansion of foliage. If therefore very thick timber of no great length be required, wide planting is proper; but if tall timber be the object, the plantation must be moderately thick.

The care which plantations require from year to year consists in making up deficiencies, thinning, and pruning. Deficiencies seldom occur if the planting be at first duly performed; and every endeavour should be used to prevent the necessity of *making up*. This is always done with considerable disadvantage to the plants thus introduced, unless the spaces be trenched; but in that case, if the species of tree be properly chosen, the plants may do well in consequence of the shelter afforded by the older surrounding individuals.

Thinning should be commenced in due time. No branch of the temporary trees should by any means overhang the top or even branches of those that are permanent. The shelter on the most exposed sides of the plantation should be formed of robust, vigorous, growing kinds, and it should be allowed to remain unbroken. Plantations that have been neglected till they have formed a dense thicket must be thinned gradually; for if thinned at once, those left would be injured by the sudden exposure, and would be blown over by winds.

Pruning is an important operation in the management of plantations, but it is often improperly practised for want of the knowledge of a few physiological facts, which are essentially necessary to be stated before any rules for pruning can be properly given. If these facts be understood few rules will be required, but otherwise a volume of directions are liable to be misapplied. It ought therefore to be understood, that the sap ascends from the stem chiefly through the alburnum, or outer layers of young wood. It then enters the leaves, when it is exposed to the influence of light. Having in consequence undergone an elaboration, it descends on the outside of the alburnum, that is to say, through the inner bark. the internal surface of the latter possessing a great degree of lubricity, whereby the passage of a portion of the juices at least is facilitated to the roots, whilst part is detained and becomes organised by the action of the medullary rays, forming a new layer of woody matter. The thickness of the layer so formed is very different in different species; but in the same species, all other circumstances being the same, it is in proportion to the surface of leaves. The aggregate horizontal growth, or in other words the diametrical extension of the stem, branch, and even roots, depends upon the quantity of healthy foliage. The diametrical increase of any particular part corresponds with the greater or less proportion of foliage above that part. Again, it may be stated that if any one tree has a clear stem of 20 feet in length, and another has one of 40 feet, the roots and foliage of both being equal, the layer of new wood will be much thinner in the latter case than in the former; for the deposition of woody matter will have to extend over double the surface in the tall tree. It may be also remarked, that, in general, if a tree be left entirely to nature, it will ultimately produce a greater bulk of wood, taking stems and branches together, than would be the case if subjected to pruning. Except however in the case of growing for fuel, pruning is more or less necessary. The value of a timber-tree depends chiefly on the stem, the branch timber being of less value. The object to be kept in view in pruning for timber is the production of a clean stem with as small a proportion of branches as possible. But it has been explained that the growth of the stem depends on the quantity of foliage, and without branches a sufficient quantity of foliage cannot be maintained. Whilst, on the one hand, an undue preponderance of branches is prevented by pruning, yet, on the other, as much foliage should be preserved as circumstances will permit.

An excessive privation of foliage should never be occasioned at any one time. It is therefore advisable that pruning should be commenced early, in order. as it were, to repress irregularities in the bud. At all events, whenever an irregularity can be clearly distinguished as such, it should be checked. Thus, when a shoot, occupying the position of a branch, ascends in competition with the top, or leading shoot, and is allowed to go on for years, the stem will have a forked character; or if the competing portion be amputated after it has acquired a large size, the timber will be rendered unsound. But if the shoot from which this aspiring limb took its rise had been stopped in the first or second season of its growth in summer, the tree might have been grown with a clean regularly tapering stem. It is only great irregularities however that should be meddled with during the early growth of the plant; otherwise the increase of roots is prevented, such increase being reciprocal with that of the branches.

Young shoots of the above description may be checked by being shortened in summer; but no large branches should be cut off at that season, nor after the sap begins to flow briskly in spring. Towards autumn, however, when the leaves have nearly ceased to carry on their functions, pruning may be very properly performed; and some species, for example the birch and maple, require to be pruned at that time, otherwise they are apt to bleed. The period at which *bleeding*, that is, an extravasation of sap, takes place with greatest force, is immediately before the bursting of the buds in spring. If a branch be cut off when in foliage, the remaining portion draws the sap and prevents effusion at the wound. Some derangement will of course be produced in the flow of sap; and a diminution of the process of lignification and of the formation of roots will be occasioned, owing to the abstraction of a certain extent of foliage. But when the sap is in motion, and the leaves at the same time not expanded, the amputation of a branch is followed by a flow of sap, which appears to drain from every part of the tree. The sap becomes stale on exposure to the air; it then affects the cambium and inner bark, often to a considerable extent below the wound, and if these are not in all cases so far completely killed, yet they are generally more or less injured, and canker is apt to ensue.

Supposing it were required to rear a tree so as to have a stem of clean-grown timber, as tall and as thick as could possibly be obtained in any given time. The first consideration is the root, the plant being supposed to be young, with a top or upright leading shoot, and several side branches. All these should be left undisturbed in the first instance, unless such of the latter as may require a check if growing too strong for the others or for the leader. The laterals should be left, for the sake of the roots, till their presence on the stem becomes inconsistent with the object of producing it as free as possible from knots, taking also into consideration that the difficulty in healing the wound increases as the branches get older. A *few* of the largest shoots should be those first removed. They may be shortened in the first instance after midsummer, and afterwards cut off smoothly by the lowest circular wrinkles which form round their base, close to the stem, but without slicing off a portion of the bark; a slovenly practice, of which only bad pruners are guilty, and which can only have the effect of diminishing the power of the bark to close over the wound necessarily made by the pruning-knife. Such unnecessary wounds cause an extravasation of sap, as may be seen especially in coniferous trees, where they are generally covered with resinous exudations. In the following season the next largest branches should be in like manner displaced, care being still taken, on account of the importance of the foliage, as already explained, that the quantity removed shall be no more than is absolutely necessary.

Small branches along the stem should be left till they approach the dimensions by which the removal of the others is regulated. These principles should be followed up till the required height of stem is attained; after which the branches composing the top shall be allowed full freedom, in order to increase, by their organising power, the diameter of the stem.

Coniferous trees require little pruning; nor is it necessary to commence so early with them as in the case of other kinds. In dense forests they are found with straight stems approaching the height of 100 feet clear of side branches, the latter gradually decaying below as they become excluded from light and moisture by those above them. When from this cause the lower branches of coniferous trees are observed to lose in a great measure their vigour, and when their foliage contributes little to the enlargement of the stem, they may then be very properly cut off, without waiting for their actual decay. It is a question whether the branches of these trees should be cut close to the stem at once, in pruning; or whether they should first be *snagged*, that is, cut at some distance from the stem, and either allowed so to remain or be afterwards cut close. That plan is best to adopt by which the least exudation of resinous substance is occasioned, and the blemish soonest overgrown. With the view of preventing the former, the branch may be shortened only to the first live twigs, so as almost to nullify its connection with the stem, preparatory to its final and close removal in the following season.

By choosing the proper season, and by previous shortening, large limbs of any healthy tree may be closely amputated so as to heal over without affecting the tree generally, or even the portion of stem more immediately connected with the limb to any material extent; yet the new layer of wood will prove, on cutting up the timber, to be only in close contact with the surface of the wound, which will remain dead, and with which the living matter enclosing it could not coalesce. A piece of unsound wood is thus embodied. In this case it would be advisable to shorten the limb to such of its laterals as will just be sufficient to keep it alive till the tree is felled. If, in the interval, the branch should push vigorously, means must be adopted to keep it always in a reduced state, by merely allowing as much foliage as will keep the branch alive, without affording any material addition to its diameter.

The proper season for felling trees is when the sap is most at rest. The operation ought not to be performed at any other time, unless for fire-wood. The quantity of sap that may be drawn from some trees is very great. This sap contains the elements of fermentation, the powerful effects of which are evident even on the strong fibre of the oak. Softer woods, although very tough if cut at the proper season, have been observed to crumble almost to powder in a year or two, in consequence of having been cut when in sap.

PLASTER OF PARIS. [CALCIUM; *Sulphuric Acid and Lime.*]

PLASTERING. The application of any coat of plastic material to the uneven surfaces of masonry or of wood-work, for the purpose of bringing the latter to a sufficiently smooth surface to receive elaborate surface decoration, is known by the generic name of plastering; but in practice a distinction is made in order to separate the more elaborate processes of the plasterer's art, which are known by the names of stuccos, scagliolas, &c.

Ordinary plastering is either executed with the pure dehydrised sulphate of lime (or the baked gypsum), or with mortars composed of the carbonates of lime, forming a substratum to receive ultimately a finishing coat of fine plaster; the choice between those materials being decided by motives of economy, for the gypsum does not occur in large quantities, or over large areas, although it is found in a great many countries. When the carbonates of lime are used for plastering, great precautions must be taken to ensure their perfect hydration before they are put upon the walls, as any unslaked lime will be sure to attract moisture from the atmosphere, and to slake, or, as the workmen say, "to blow." Near London the usual practice is to cover the walls with a rough coat of lime so slaked, mixed with sand and with cows' hair, for the purpose of counteracting the tendency of the lime and sand mortar to contract unequally, and thus to crack, in setting. This coat is called the *rendering coat*, and in good work it is left with a roughly trowelled face, able to *form a key* for the further finishing coats; but in commoner descriptions of work, known as *laid work*, the rendering coat is at once *floated*, or worked to such a surface as to be fit to receive the finishing coat. In good work upon walls, the rendering coat is then covered with a second coat, called the *floating* one, with which great pains are taken to secure its verticality and its evenness; and upon this again the *setting coat* of pure lime is applied, which is trowelled up with more or less care according as the surface is intended to receive paper or paint. Upon ceilings, or wooden partitions, the several rendering, floating, and setting coats are applied, in the same order as above, upon laths; and the laths themselves are either prepared from oak or from fir. In ceilings, however, it is customary to add, after the setting coat, a very fine one, composed of the sulphate of lime, or of what is commonly called the "plaster of Paris," whether obtained from our own or from foreign quarries.

The manner in which plastering is executed in Paris itself may be considered to present the best type of the application of the sulphate of lime for that purpose. The gypsum there used is obtained from the quarries of Belleville, Montmartre, Triel, or Vaux, and it is usually dehydrised in kilns heated by wood; the stone is said to contain a certain proportion of the carbonate of lime, and it certainly is harder than the English gypsum, on which latter account it may be that the French plastering is so much harder than the plastering executed with the Derbyshire gypsum. Workmen, indeed, consider it an axiom, that "the harder the stone, the harder the plaster." After the gypsum has been burnt, it is ground or pounded, and applied to the walls as soon as possible after that operation; the coarser kinds are used to render the uneven surfaces tolerably level, and the finishing coats are executed with the finer materials. The rough rendering is often laid on with a broom, and the setting coat is applied upon it by the application of rather stiff plaster floated under a rule, but finished immediately with the trowel; in fact, ordinary French plastering is no better than English laid work, and it is quite as uneven and as irregular as the latter. In the execution of their ceilings, the French plasterers adopt a different system from the one used in England; for they generally nail their laths at wide intervals, and upon them they lay slabs of old or rough plaster, which they bind together by new materials, so as to produce, as it were, a single solid slab of light plaster over the whole ceiling, which is subsequently made smooth on the under side by the addition of a setting coat. This description of ceiling is heavier than the English ones; but it resists the transmission of fire more successfully, and it is also less permeable by sound: the latter inconvenience of English ceilings is sometimes obviated by the introduction of sound boarding, or of pugging—which, however, are objectionable on the score of their tendency to develope the dry-rot in the joists of the floors.

There is one remarkable difference in the action of the lime plastering and of the gypsum plastering, arising from the fact that the crystallisation of the latter is accompanied by an expansion so energetic, that if it be not provided for very serious accidents would occur; whereas the lime plastering, as a general rule, has a tendency to contract. Of whatever materials the body of the plastering may be formed, the finer mouldings, and all the cast ornaments, are executed in fine plaster, unless the cements, or the prepared sulphates of lime, known as the Parian, Keene's, or Martin's cements, are used. The class of materials last named are obtained by the calcination of a previously dehydrised sulphate of lime, soaked in solutions of alum, borax, &c.; and they produce remarkably hard and smooth surfaces, admirably adapted to receive paint; unfortunately, their use is costly.

Stuccos are made by the application, as a setting coat, of lime mixed with calcareous powder, plaster, and other ingredients, which is trowelled up by dint of excessive labour to a fine surface resembling marble, and able, like marble, to receive a polish. Different colours are given by mixing with the lime the metallic oxides of the required tints; and the polishing is effected only when the whole of the moisture has worked out of the lime. The mode of polishing is by the use of fine grits, tripoli powder, and oil rubbers, in nearly the same manner as for marble. Scagliola is in fact a species of stucco, but it is executed by the introduction of small particles of fine spars, or of coloured marble, into the rendering coat, in addition to the simple lime powder, so as to produce the effect of the more ornamental descriptions of marble breccias. Both these ornamental kinds of work are adapted for internal decoration, but externally they are exposed rapidly to decay. It may also be added that, in the construction of concert, or even of debating-rooms, it is preferable to finish the walls with ordinary plastering than with stucco, or scagliola, for the latter materials are so elastic that they reflect sound in a manner to interfere with the purity of the tone.

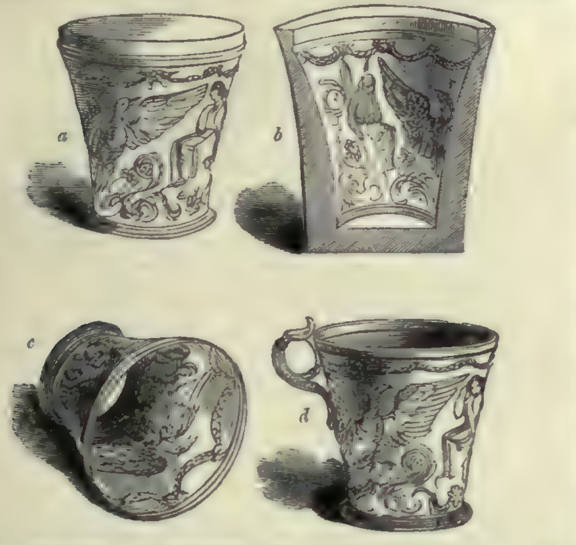
Whatever mode of plastering may be adopted, it is essential that the walls on which it is applied should be perfectly dry, and perfectly impermeable, if any elaborate surface decorations are to be applied to them. Great precautions must also be taken to secure the absence of organic matters in the materials used, for if any of them should be present, the nitrogen salts will be thrown out, under such circumstances as to destroy any painting or papering on the walls. It is precisely to the neglect of this precaution that we may attribute the loss of so many noble fresco paintings.

PLATE; PLATING. In the article JEWELLERY, JEWELLING, it is explained that under the general name of *plate* are included the productions in gold and silver which are stamped at Goldsmiths' Hall and similar places, while *jewellery* comprises the smaller articles which are not so stamped.

Confining our attention to plate, properly so called, it may be stated that all such articles made in and near London must be sent to Goldsmiths' Hall, after having been stamped with the maker's mark. Persons used to the work scrape off a few fragments for the purposes of assay; if this be found to be below the standard (in gold 18 carats fine), the article is broken up; if of proper standard, it is stamped and returned. Most of the plate is made in and near Clerkenwell, although the chief goldsmiths have their retail establishments at the West End or in the city; and there is at all times a busy system of transmission between Clerkenwell and Foster Lane, where the assay office of the Goldsmiths' Company is situated. The company receive fees for assaying and stamping, amounting in the aggregate to about 4000*l*. a-year, from the manufacturers. They also receive about 2000*l*. a-year from the government, for their trouble in collecting the Excise duty on gold and silver plate, and paying it into the Bank of England. This curious arrangement seems to have arisen from the circumstance that, as it is a part of the company's duty to ascertain exactly how much precious metal there is in each manufactured article, they have the means at once of stating how much duty is payable to the government, at a certain rate per ounce. This rate is 17*s*. for gold and 1*s*. 6*d*. for silver, if estimated at the full weight; but as there is always a slight reduction of weight during the finishing processes which follow the assaying and stamping, the government take off one-sixth of the duty, leaving it at about 14*s*. 2*d*. and 1*s*. 3*d*. respectively. There have in recent years been about 50,000 of these assayings made in a year. The assayers are not allowed to know from whose manufactured goods the particles have been scraped off; each packet is opened, assayed, and reported on with perfect fairness. If any manufacturer has erred frequently by sending in goods below the standard, the officer who receives the goods may direct any subsequent specimens from him to be tested with additional severity. Out of London, the towns in which the largest amount of gold and silver plate is manufactured are Birmingham and Sheffield; halls or assay offices are established there, with duties nearly like those of Goldsmiths' Hall; and at those places a curious operation is conducted, relating to *diets* of gold and silver. An assayer scrapes eight grains from every troy pound of plate manufactured, and divides it into two portions, one of which is at once assayed; the other is placed in a receptacle called the *diet-box*, which, at the end of the year, contains specimens from all the articles manufactured. This box is sent up once a year to London, where the assay master of the Royal Mint assays a fair average of all the small portions which it contains: if this average reaches the standard, the assayer at Birmingham or Sheffield receives a certificate; if below the standard, he is fined. There are a few other assay offices in the United Kingdom, each having control over the gold and silver plate made within a certain district. The Goldsmiths' Company have often petitioned for the abolition of these country offices, on the plea that the assays are more scrupulously made by the company's servants than by those of the local halls; but it is difficult to get rid of the influence of self-interest in connection with any such plea. It is admitted, however, that plate stamped with the London hall-mark commands a higher position in the market than that which has only a country stamp. In recent years there have been (in round numbers) about 10,000 ozs. of gold plate, and 1,000,000 ozs. of silver plate, assayed and subjected to government duty annually in the United Kingdom.

The manufacturing operations do not call for detailed notice here. The processes of rolling, casting, punching, chasing, hammering, stamping, soldering, riveting, and burnishing, all come into requisition in the manufacture of a piece of plate of any considerable size or elaboration of design.

The proportion, however, of articles of plate made of real gold or silver throughout is very small compared with that of articles in which the surface only is of precious metal, laid upon a metal of cheaper character. By pressure between steel rollers, a thin layer of gold or silver may be made to adhere to a thicker layer of some cheaper metal, and of the compound layer thus produced numerous articles may be made. A class of goods called *Sheffield plate* used to be very largely manufactured of such compounds. The product has been considerably improved by the adoption of a white metal for the ground or foundation. This white metal is usually a compound of nickel with certain other metals; and the colour bears a sufficiently close resemblance to that of silver to render it advantageous in all, since it will not show a coppery or brassy tint when the silver is worn away. Articles of real silver plate are sometimes coated with real gold on one side, or in certain parts, and these obtain the designation of *silver-gilt*. The whole trade, however, has undergone a revolution within the last few years, by the introduction of the process of *electro-metallurgy*, or *electro-plating*. By this process a work of art may be made wholly of gold or silver, or of a film of those metals on a ground of less value, by deposition from certain chemical liquids through the agency of a galvanic battery. The processes are explained under ELECTRO-METALLURGY. The annexed wood-cut will illustrate the remarkable series of operations (as described in that article) by which the better kinds of electro-plate are produced: *a* is a model for a silver cup, formed of wax or composition, and sculptured with an artistic design on the outer surface; *b* is one half of an elastic mould, made of caoutchouc and other substances, and obtained by casting from the model, with the device inside instead of out; *c* is a copper cup obtained by electro-deposition upon the interior of the mould, and afterwards detached from it; *d* is the finished cup, with an electro-silver surface upon an electro-copper ground, and a handle attached. If possible, white metal is used instead of copper as a basis.



There are many curious modes of coating plates of metal with thin films of other metal, wholly distinct from those in which gold and silver are employed. Most of them, however, bear analogy to TINNING or TIN-PLATING, and will be briefly adverted to in that article.

PLATFORM, Military, is the floor of wood or stone on which heavy guns are placed in order to be more easily worked. In fortresses the platforms are occasionally made of stone in order to withstand long exposure to the weather, but in field-works they are always of timber. For guns the platforms are laid with a slight rise to the rear (about ¼ inch in the foot) to enable the gun to be more readily run up after the recoil. The mortar platforms are laid level. The ordinary gun and howitzer platform which, when laid, forms a rectangle 15 ft. long by 10 ft. 6 in. broad, consists of the following pieces:—

5 sleepers, each 15 feet long × 5 in. × 5 in.
20 planks „ 10½ „ 9 „ 2 „
2 ribbands „ 15 „ 4 „ 4 „
10 rack-sticks and lashings, or iron bolts.

The weight of the platform is about 14 cwt.

The sleepers are first laid in the direction of the line of fire in cuts or trenches made in the ground, which has been previously levelled, and are firmly pinned down. They are then covered with the planks, which are laid at right angles to the line of fire, and, the ribbands being placed directly over the outside sleepers, are fixed down by the rack-lashings, which have been placed, five on each side, under the sleepers before they were laid.

The platforms may be fixed with screws, or spikes, instead of rack-lashings; but this, besides injuring the wood for further use, should it be necessary to move them, is a noisy operation, likely to attract the enemy's attention if the batteries are close to his works.

There is a description of gun-platform invented by Colonel Alderson, R.E., in which all the pieces, superstructure, and sleepers are of the same size, and are fitted together with dowel pins.

Platforms for mortars, which are laid horizontally, are generally 7 ft. 6 in. by 6 ft. 6 in. In order to resist the effect of the recoil of the mortar, which is fired at an angle of 45°, the sleepers and planks are stronger than in the gun-platform, and seven sleepers are used instead of five. Two sleepers being first laid transversely, then the five across them, and then the planking.

Madras platforms for guns are composed of a strong framework of wood, consisting of two side pieces, 12 ft. 6 in. long and 9 in. × 4 in., on which the wheels of the gun run, and two trail pieces 12 ft. 6 in. long and 4 in. square, for the trail of the gun (this platform being used for guns on travelling carriages). The whole platform is kept together and strengthened by a front and rear transom and three sleepers, to which the side and trail pieces are bolted down. The front transom is fixed close to the parapet, and the platform has a rise to the rear of 8 inches. This platform is very good for siege purposes, and when no great lateral splay is required; for when it is necessary to change the line of fire the whole platform has to be traversed with handspikes. Siege platforms, as has been stated, are generally made rectangular; but the stone platforms used in permanent works are made wider at the rear, so as to allow the guns a greater splay. This is not so much required in siege works when the guns have a fixed object, and would further make the platforms more complicated and difficult to lay at night, while the pieces not being uniform would not be interchangeable.

In fortresses, at the salients and in casements, and in coast batteries, the guns are now often mounted on traversing platforms. The gun is then raised on a platform which traverses on runners, the pivot being fixed either in front, centre, or rear.

PLATINAMINE. [PLATINUM.]

PLATINO-HYDROCYANIC ACID. [CYANOGEN; HYDROPLATINOCYANIC ACID.]

PLATINUM (Pt). The natural history of this metal has already been given. [PLATINUM, in NAT. HIST. DIV.] It has been very much used during the last fifty years in those experimental and manufacturing operations in which vessels are required that are not acted upon by hydrochloric, nitric, or sulphuric acids. Platinum knives, crucibles, capsules, and dishes, are commonly employed; while stills weighing from five hundred to one thousand ounces are not unfrequently made use of for concentrating oil of vitriol.

The metallurgy of platinum has of late years received considerable attention, and been greatly improved by MM. Deville and Debray. Their memoir appears in the 'Annales de Chimie et de Physique' for August, 1859, and is abstracted in the 'Pharmaceutical Journal' and 'Chemical News': its title is, "On Platinum and its Associated Metals." The following table exhibits at a glance the composition of platinum ores from various sources; for details concerning methods of analysis, see the paper above referred to.

	Columbia.	California.	Oregon.	Spain.	Australia.	Russia.
Platinum . .	80·00	79·85	51·45	45·70	59·80	77·50
Iridium . .	1·55	4·20	0·40	0·95	2·20	1·45
Rhodium . .	2·50	0·65	0·65	2·65	1·50	2·80
Palladium . .	1·00	1·95	0·15	0·85	1·50	0·85
Gold . . .	1·50	0·55	0·85	3·15	2·40	
Copper . .	0·65	0·75	2·15	1·05	1·10	2·15
Iron . . .	7·20	4·45	4·30	6·80	4·30	9·60
Osmide of iridium	1·40	4·95	37·30	2·85	25·00	2·35
Sand . . .	4·35	2·60	3·00	35·95	1·20	1·00
Osmium and loss		0·05		0·05	0·80	2·30
	101·15	100·00	100·25	100·00	100·00	100·00

The preparation of pure platinum from the ore is effected as follows. The ore is fused in a reverberatory furnace with an equal weight of galena, care being taken to avoid as far as possible any rapid oxidation of the lead. The mass is well mixed so as to convert all the iron into sulphide, and to produce an alloy of the platinum with lead; some glass is then added, and sufficient litharge to effect the decomposition of all the sulphides. The metal is then allowed to remain perfectly undisturbed for some time in order that the osmides may settle down and collect in the lower portion of the mass. The scoria is then removed; the alloy of platinum and lead run off, except the lowermost portion which contains osmium, and the lead finally removed by the ordinary process of cupellation. The fusion and refining of the resulting platinum are effected in furnaces made of solid lime and heated by a large jet of oxygen and hydrogen gases.

Nearly all the platinum at present met with in commerce contains traces of osmium and a little silicium, but these may be perfectly removed by prolonged fusion in the oxyhydrogen furnace just mentioned.

Pure platinum is a white metal of the same softness as copper, and is susceptible of high polish. It slowly volatilises at a temperature considerably above its melting point, and, on quickly cooling, bubbles and spirts like silver. In tenacity and ductility it is superior to all metals except iron. Its specific gravity is 21·15; or after hammering, 21·5. As a conductor of heat and electricity, it is inferior to gold and silver. It has the property of condensing gases on its surface, and when once heated to redness remains red hot for some time if a jet of cold hydrogen or coal gas be impinged upon it. Platinum is not tarnished by exposure to air, is unaffected by all acids except aqua regia, and is not acted upon by dry chlorine. It very readily combines with other metals, so that nothing that contains, or is likely to yield, a metal as such, should be heated in vessels of platinum. Alkalies also corrode it through formation of a double oxide.

Chlorides of Platinum.—Platinum dissolves in a mixture of three parts hydrochloric acid and one part nitric acid. Such a mixture (aqua regia) contains free chlorine, which unites with the platinum to form *bichloride of platinum* ($PtCl_2$). The latter may be obtained in deliquescent prismatic crystals on evaporation. It is very soluble in water, alcohol or ether. On heating it to 450° Fahr., half the chlorine is expelled, and *protochloride of platinum* ($Pt\,Cl$) remains. Both chlorides form crystalline double salts with alkaline chlorides. The *potassio-chloride of platinum* ($KCl, Pt\,Cl_2$) is so sparingly soluble in water, that its formation is of considerable value as a qualitative test for potassium. Its insolubility in alcohol and ether admits of its being used as a means of quantitatively estimating potassium. The *ammonio-chloride of platinum* ($NH_4Cl, Pt\,Cl_2$) is isomorphous with the potassium salt, and is thrown down as a crystalline yellow precipitate on adding together tolerably strong solutions of bichloride of platinum and chloride of ammonium.

Oxides of Platinum.—The *protoxide* ($Pt\,O$) is a black precipitate, formed on digesting the protochloride in caustic potash, and neutralising with sulphuric acid. It forms unstable salts with acids. The *binoxide* ($Pt\,O_2$) is precipitated as a bulky brown hydrate, on adding carbonate of soda to excess of nitrate of platinum. It forms crystalline compounds with the alkalies and with acids.

Sulphides of platinum are formed by the action of sulphuretted hydrogen on proto- and bi-salts of platinum. The *protosulphide* ($Pt\,S$) is gray, the *bisulphide* ($Pt\,S_2$) black.

Iodides of platinum are produced by acting upon the chlorides with iodide of potassium. The *protoiodide* ($Pt\,I$) is black; the *biniodide* ($Pt\,I_2$) is deep wine-red.

Bibromide of platinum ($Pt\,Br_2$) is a brown insoluble powder.

Nitrate of platinum ($Pt\,O_2, 2NO_5$) remains in solution when nitrate of potash is added to bichloride of platinum so long as potassio-chloride of platinum is deposited.

Compound platinum and ammonia bases. Platosamine, platinamine, &c.—By the action of ammonia on protochloride and bichloride of platinum, and by the action of nitric acid, &c., on the resulting products, a series of remarkable compounds have been produced by Gros, Reiset, Gerhardt, and Raewsky. These bodies seem to be derivatives of hydrated oxide of ammonium, containing platinum in the place of hydrogen: they bear a striking resemblance to the ammonium ORGANIC BASES.

Spongy platinum is a dull-gray, soft, porous form of platinum, having somewhat the appearance of sponge. It is produced on simply igniting the ammonio-chloride of platinum. It possesses in a high degree that power of inducing the combustion of inflammable gases in the manner already alluded to. When freshly prepared, it causes the inflammation of a jet of hydrogen on the latter being impinged against a small pellet of it. By great pressure spongy platinum is condensed into laminæ having the metallic lustre.

Platinum black differs from spongy platinum, not only in colour, but in being perfectly amorphous. It is also in a still finer state of division, and possesses in the highest degree the power of condensing gases upon its surface and of inducing the combustion of gases and vapours. It is prepared by adding to bichloride of platinum, first protosulphate of iron, then caustic soda, and afterwards hydrochloric acid; or by precipitation from the chloride by means of metallic iron reduced by hydrogen from the oxide obtained on igniting the oxalate of iron.

Alloys of platinum.—Platinum forms an alloy with tin, which crystallises in cubes, and contains Pt_2Sn_3. With twenty-five per cent. of iridium, or with nineteen and a half per cent. of iridium and five per cent. of rhodium, platinum forms alloys that are perfectly malleable: they may be worked into vessels that are almost unacted upon by aqua regia, and which, from their greatly increased rigidity, retain their shape longer and better than if constructed of platinum alone.

Detection of platinum.—The production of the yellow crystalline precipitate with chloride of ammonium, which becomes converted into a spongy metal on ignition, is sufficiently characteristic of platinum.

Estimation of platinum.—This may be effected in the state of spongy platinum produced as already directed; or, on a tared filter, as ammonio-chloride of platinum which contains 44·28 per cent. of metal; or as potassio-chloride which contains 40·43 per cent. of platinum.

PLEA. [PLEADING.]

PLEADING at Common Law. Pleadings are the allegations of the respective parties to a cause expressed in technical language. In order that a correct decision may be made upon disputed rights, it is necessary that the points to be decided should be clearly ascertained, and this is effected by the system of pleading, whereby the precise points in controversy are presented for decision, unencumbered with extraneous matter.

Actions are now commenced by writ of summons, calling upon the defendant to *appear*, or otherwise the plaintiff will proceed to judgment and execution. If the defendant fails to appear, the plaintiff obtains a judgment by default. If he appears in court to answer the proceedings against him, he is then entitled to receive from the plaintiff a detailed statement of the nature of his complaint, which is called the declaration, *narratio*, or count, though the last of these terms is now more commonly used to denote one of several distinct matters of complaint comprised in the same declaration.

Eight days after the delivery of the declaration, the time for pleading arrives; the term "pleading" being not only used in the extensive sense mentioned above, but also in the limited sense of the answer, whether consisting of statement or of denial, which is made by the defendant to the declaration. In answering the declaration, the defendant is not allowed to accumulate his objections both of law and of fact in one defensive pleading. The peculiarity of our system in referring matters of fact to the decision of a jury, and of leaving questions of law only to the judges, has created a necessity for separating the matters of law from those of fact, and of presenting the latter in a shape in which they can be readily understood by persons who are not lawyers by profession. It is to the severe analysis required by this feature of our jurisprudence that the system of pleading is probably indebted for its excellence.

If, when called upon to plead, the defendant fails to do so, he is supposed to admit the complaint set out in the declaration, and therefore the court pronounces judgment against him upon his default, or, as it is termed, by *nil dicit*, those being the words by which the default of a defendant was formerly recorded. He may, however, decline to answer the charge contained in the declaration, on the ground that the court has no jurisdiction of the matter; or that the plaintiff is not entitled to sue, as being an outlaw, foreign enemy, or the like; or that the defendant cannot be sued alone, as being a married woman, or as a party to a contract which forms the subject of the action, that he is sued without his co-contractor being made a co-defendant in the action. This is called *pleading in abatement*, because the defendant prays that the court will abate (put down) or quash the proceedings. The defendant may also pass by these pleas, and admitting, for the present purpose at least, that the facts stated in the declaration are true, may insist that the facts give the plaintiff no cause of action against him; he may accordingly rest (demur) upon the facts as they appear in the declaration, and call upon the court to give judgment in his favour upon that state of facts. This form of pleading is called a "*demurrer.*" Or, finally, the defendant may answer the complaint, or, as it is technically called, he may "plead to the action;" and that in one of two ways: he may deny one or more of the material allegations in the declaration which is necessary to the maintenance of the action: or plead one sweeping denial of the whole declaration, which is called pleading the "*general issue;*"—which pleas are supposed to "conclude to the country," that is, the defendant in them states his readiness to submit to the decision of a jury (who are called "the country," as contradistinguished from the "court") the truth of the matter of fact asserted in the declaration and denied in the plea. It is the same if the plea asserts a fact denied in the declaration; and in either case the defendant is said to *take issue.*

Another mode of "pleading to the action," is by putting in a "*special plea,*" which either expressly, or, according to modern practice, tacitly, admits the truth of the allegations contained in the declaration, but which not only confesses but also avoids them. The special plea (whence the whole system is often called "special pleading") introduces some new fact or facts, the effect of which, if true, is to show that notwithstanding the facts alleged in the declaration, the plaintiff is not entitled to maintain his action. As it is yet uncertain whether the plaintiff will deny this new matter or will admit it to be true, there can be no conclusion to the country upon such a plea, but if that new matter contain an affirmative proposition, the defendant is supposed to conclude his plea with a *verification*, that is, an offer to prove it if its truth should be controverted on the other side. This is called "tendering an issue."

This special plea may also consist of those facts, on which a court of equity would relieve the defendant against the plaintiff's claim, and is thence called an *equitable defence.*

The next pleading on the part of the plaintiff will be regulated by the course pursued by the defendant. If the defendant has pleaded in abatement, the plaintiff either acquiesces in the action being quashed, or he demurs to the plea as not showing sufficient matter for quashing the proceedings, or he replies to the plea either by taking issue (denying) some material allegation in the plea, or by confessing and avoiding the plea, alleging some matter which, consistently with the truth of the plea, destroys its effect and shows that the proceedings ought not to be quashed, or amends his proceedings. If the plaintiff demurs to the plea in abatement, the defendant must either abandon that plea and put in a plea to the action, or he must join in demurrer. If, upon the argument of the demurrer, the court are of opinion that the plea in abatement is good, they give judgment that the proceedings be quashed: if they are of opinion that the plea is bad, the judgment is, that the defendant answer over (quod respondeat ouster), in other words, that he plead to the action.

If the plaintiff take issue upon the plea in abatement, the defendant is bound to join issue, that is, to accept the mode of trial offered, and if upon a trial the issue be found for the defendant, he has judgment that the proceedings be quashed; but if the verdict be for the plaintiff, the judgment is, not that the defendant answer over, but that the plaintiff recover his demand against the defendant.

If the defendant has demurred to the declaration, the plaintiff either abandons the action or he applies to the court for leave to amend his declaration; or he joins in demurrer, asserting that the declaration is sufficient to support the action. This demurrer and joinder form "an issue in law," or a question between the parties to be decided by the court after hearing the matter of law argued on both sides.

The plaintiff's answer to the defendant's plea, whether in abatement or in bar, is called a *replication*. If the defendant has taken issue, by pleading in denial of part or of the whole of the declaration, the plaintiff joins issue. If the defendant has pleaded specially, the plaintiff may either take issue upon the new matter alleged, or he may plead new matter, thus in his turn confessing and avoiding the defendant's plea, doing this by *equitable replication* if the case admits of it. Whenever in the course of the pleading in a cause one party takes a proper issue upon an allegation of his adversary, that adversary is bound to join issue and go to trial before a jury; but when, instead of taking issue, new matter is pleaded, the adversary has the option of taking issue upon that new matter, of confessing and avoiding it, or of demurring to it. As the pleadings may thus go on through several more stages, names have been devised for those which most frequently arise. The defendant's answer to the plaintiff's replication is called a *rejoinder*; the plaintiff's answer to the rejoinder is called a *surrejoinder;* the defendant's answer to the surrejoinder is a *rebutter*; and the plaintiff's answer to the rebutter is a *surrebutter*. The proceedings might go on ad infinitum, but for a very salutary rule which forbids a party from alleging anything inconsistent with, or even not corroborative of, his previous pleading. A violation of this rule is called "*a departure in pleading*," and if not amended is attended with fatal consequences to the party guilty of it.

The above is a short and necessarily incomplete sketch of the course of pleading at common law, without defining the strict rules by which the altercations between the parties are carried on, the object of which is to develope the precise points in controversy between parties, and to present them in the most convenient shape for decision. Of these rules Lord Mansfield observes: "The substantial rules of pleading are founded in strong sense and in the soundest and closest logic, and so appear when well understood and explained; but by being misunderstood and misapplied, are often made use of as instruments of chicane." The object of most of the new rules of pleading has been to prevent this misapplication as well as to lessen expense, though, as might be expected, in order to avoid an evil practically felt, restrictions have been introduced which are found to be productive of as much inconvenience as that sought to be remedied.

Where a point is raised which is found to consist wholly or principally of matter of fact, the parties, provided there has been a correct application of the rules of special pleading, are distinctly apprised by the pleadings of the exact nature of the question to be decided by a jury, and are thus enabled to direct their attention to that question, and prepare their proofs with reference to that question only. If the point in controversy is found to resolve itself into a question of law, a decision may be obtained by submitting the matter to the opinion of the court after argument upon demurrer, without the trouble, expense, and hazard of a trial before a jury.

We possess very little information as to the mode of pleading previous to the Conquest. At or soon after that period an important revolution took place. The pleadings in the Aula Regia, and afterwards in the courts which branched out of it, appear to have been conducted viva voce in the French language, by Norman advocates called "countours." After a discussion before the court as to the proper form of pleading [SERJEANTS], the pleadings were minuted down by the officers of the court in the form in which they had been finally agreed upon. Thus, little or no inconvenience arose from the prohibition which existed against the making of any alteration in the pleadings after they were entered. In the reign of Edward III. the pleadings were directed to be carried on in English, and the entries of these pleadings to be in Latin. Afterwards a custom was introduced of preparing the pleadings out of court and delivering them to the officers to be entered. In consequence of this arrangement defects in pleadings were not discovered until a period at which the parties were bound by them as being entered, and it became necessary for the legislature to interfere in order to allow amendments to be made in some cases, and in others to direct the judges to pronounce judgment without regard to formal objections. By the late rules all pleadings must be *delivered* by the one party to the other. ('Blackstone's Com.' Mr. Kerr's ed., vol. iii., *passim*.)

PLEADING IN EQUITY. The following remarks may serve to show how far Pleadings in Equity differ from Pleadings at Law, from which they are derived; and they may be taken as supplemental to the article EQUITY, in which a reference is made to this article.

The Answer in Equity differs materially from the answer at Law, in being upon oath, except in the case of persons who have privilege of peerage, or are Quakers or Moravians, and in the case of a corporation; and the plaintiff may use the whole of the defendant's answer as evidence against him at the hearing of the cause, or such integral part of it as he may think proper. He may also, by means of the admissions contained in the answer, obtain the inspection of books, papers, and writings in the defendant's possession, which support his (the plaintiff's) claim, and he may use them as evidence at the hearing of the cause. The defendant, except on the question of costs, can make no use of his own answer, further than as showing what his defence is; and he must support this defence by evidence, just in the same way as the plaintiff must prove those parts of his case which he cannot prove by the admissions in the defendant's answer. Any number of plaintiffs may join in a suit, if they have all a common interest, however unequal in value, in the subject-matter of the suit; and a common interest means such a legal or equitable title to the subject-matter of the suit, or to some part of it, as will entitle them to a decree which shall affect the defendants. All the plaintiffs in a suit are considered one, as appears from the general rule that a suit is abated by the death of a plaintiff or the marriage of a female plaintiff; and also from the rule that a person who has no interest in the subject of the suit cannot join as a plaintiff with one who has. But the suit is a different suit against each defendant, for each defendant may answer separately to the bill; and no defendant is affected in any way by the answer of a co-defendant. If a defendant dies, the suit abates as to him, but continues as to the other defendants, though it is nearly always necessary to restore the integrity of the suit by making the personal representative or the heir at law of the deceased defendant a party to it.

The writ of Subpœna was until recently the original process by which a party was brought before the court. This writ required the person to whom it was addressed to appear and answer "upon pain of an attachment issuing against his person, and such other process for contempt as the court should award." Those who had privilege of peerage were required to appear and answer by a Letter Missive from the lord chancellor. The act 15 & 16 Vict. c. 86, substitutes the service of a copy of the bill upon the defendant for the old process.

The bill is briefly and sufficiently defined to be "a declaration in writing, showing the plaintifes griefe, and the wrong which he suposeth to bee done unto him by the defendant, and what damages he sustaineth by occasion thereof, praying process against him for redresse of the same." (West, 'Simboleography,' 194, ed. 1622.) "And first the matter of every bill ought to be true. Secondarily, the same matter ought to be laid down therein plainly and certainly in every circumstance of the thing, person, time, place, manner of doing, and other accidents. And thirdly, the same ought to be sufficient in law, both for the forme thereof, and for the matter, that it be such as is examinable in this court; which being otherwise, may be dismissed thence." (West.)

A bill then is a declaration in writing of a complainant, or of several complainants who have such a common interest as may form the subject of one suit. Like a declaration at law, it contains the claim of the plaintiff and the grounds thereof. In form it is, as already observed, a petition or supplication: as it commences with words of supplication, so it concludes with a prayer for relief.

According to present practice, a bill has become a much longer declaration than formerly, which is partly owing to the more complicated nature of modern transactions, and partly to other causes. It is divided into various parts by modern writers, but in effect it only contains two parts, the declaration of the grievance and the prayer for relief. The declaration consists of what are technically called Statements and Charges; the statements are or ought to be a clear exposition of the facts on which the plaintiff founds his title to relief; and every fact which is necessary, either by itself or coupled with other facts, to support the plaintiff's prayer, should be sufficiently alleged. This rule, though it may appear vague, and would be useless to any person who attempted to draw a bill without experience in such matters, really contains all that can be said in general terms. The recent Chancery Amendment Act directs that "every bill shall contain as concisely as may be a narrative of the material facts, matters, and circumstances, on which the plaintiff relies, such narrative being divided into paragraphs numbered consecutively, and each paragraph containing, as nearly as may be, a separate and distinct statement or allegation, and shall pray specifically for the relief which the plaintiff may consider himself entitled to, and for general relief."

The statements of a bill may be followed by charges, which the above enactment does not forbid, and which are not a mere repetition of the statements, but contain certain things or facts either already stated and alleged in the charges with more particularity for the purpose of obtaining an admission from the defendant, or they contain new facts of which in like manner the plaintiff wishes to obtain an admission as evidence in support of his statement and his prayer for relief. It is also usual in the charges to suggest the defendant's grounds of defence, for the purpose of ascertaining what they are, and generally to make all such charges as, if admitted or proved, would sustain the plaintiff's claim against the defendant. Another object is to discover what defence the defendant will make. But the main purpose of the charges is to obtain from the defendant what is technically called discovery, that is, evidence in support of the plaintiff's claim, either by the admissions in the defendant's answer, or from written papers in the possession or power of the defendant. This is the great distinction in present practice between a declaration at law and a bill in equity. Both state the plaintiff's demand and the foundation of it; but the bill in equity also contains a large part of what, if proved, would be the plaintiff's evidence. Now much of this matter which is charged in a bill may be and often is entirely false, and is invented by the plaintiff for the purpose of seeing whether he cannot extract some evidence favourable to himself from the defendant. The plaintiff may invent or suggest as much false matter as he pleases, but it must be matter of that kind, which, if true, would give him a right to that which he demands of or against the defendant. Now the defendant must, if required, answer all that the plaintiff distinctly alleges in his bill, provided it be material to the plaintiff's case, or he must demur or plead to it; and he cannot demur, in the case supposed, because he thereby admits the plaintiff's case to be true, and therefore he must admit that the plaintiff is entitled to the relief which he prays. Thus the plaintiff, by means of the right which he has to compel an answer, incidentally may obtain the discovery, that is, the evidence, which he wishes to have. If the defendant can plead to the bill, he is not bound to answer beyond the plea; for a good plea is a complete answer to the whole bill, or to such part of the bill as it extends to.

Formerly, the charging part of a bill was followed by interrogatories, in which the whole of the matter stated and charged was repeated, and the defendant called upon to say yes or no, or give some explanation to every item. The recent Act has forbidden the insertion of interrogatories in the bill, and the plaintiff, if his bill be such as requires an answer, must file interrogatories for the examination of the defendants separately. The defendant need not answer except thus called upon, he may however do so spontaneously if he chooses.

"An answer is that which the defendant pleadeth or saith in barre to avoid the plaintiff's bill or action, either by confession and avoiding, or by denying and traversing the material parts thereof." (West, 194.) Thus it appears that an answer in equity is in form the same as a plea to the action at law. It must be a complete answer to everything sufficiently alleged and charged in the bill, at least to everything that is material to the plaintiff's claim. By the recent Act it is enacted, that "the answer may contain not only the answer of the defendant to the interrogatories, but such statements material to the case as the defendant may think it necessary or advisable to set forth therein, and such answer shall be divided into paragraphs numbered consecutively, each paragraph containing as nearly as may be, a separate and distinct allegation."

A defendant, as already observed, must in proper form and in due time, as prescribed by the rules of the court, answer the interrogatories upon oath, unless he has privilege of peerage, or be a Quaker, or other person who is excused from taking an oath, in which case his statement on honour in the case of those who have privilege of peerage, and in the other case his solemn affirmation, is sufficient. But the plaintiff may consent to take the answer without the defendant's oath or signature, which is sometimes done. Those who are not Christians must swear to the truth of their answer in such form as the religion which they profess declares to be a binding form.

A plaintiff may by leave of the court amend his bill either before answer or after; that is, he may strike out parts and insert new parts; and it is not easy to say what are the limits to the amount of alteration. A defendant is rarely permitted to amend his answer.

A demurrer in equity needs little explanation further than what has been given. [EQUITY.] When it is a demurrer to the whole bill, which is the most usual kind of demurrer, the object generally is to get rid of the suit, and to avoid an answer which may give the plaintiff some discovery. If the demurrer is allowed, the suit is properly at an end; but leave is often given to the plaintiff to amend his bill, particularly where the demurrer is for want of proper parties. If the demurrer is overruled, the suit proceeds.

A plea in equity may require a few words of explanation. A plea in bar to the whole bill, which is the common kind of plea, is an averment which is offered as a substantial answer to all the statements and charges in the bill, though it is not in form such an answer. In fact, a plea in equity is the same thing as a plea at law: it is the defendant's answer to the whole of what is adversely alleged, and as it does not in terms answer all that is adversely alleged, it must be taken to admit that to be true which it does not in terms answer, because the averments of the plea are offered as a complete answer to the bill. In the old books there is no distinction made between a plea in equity and an answer in equity; nor is there any difference substantially. "A plea is a special answer to a bill, differing in this from an answer in the common form, as it demands the judgment of the court in the first instance whether the matter urged by it does not debar the plaintiff from his title to that answer which the bill requires." (Lord Redesdale, in *Roche* v. *Morgell*, 2 S. and L., p. 724.) Now, as a complete answer is that which the plaintiff requires, and is entitled to if his bill is good in substance and form, and as discovery is in many cases his chief object, and in some cases his only object, it is evident that before any further proceedings can be taken in the matter of a bill to which a defendant pleads, it must be determined whether the plea is good in form: and for this purpose the averments of the plea must be considered as true; and all that part of the bill must also be considered as true to which the plea is no direct answer.

Now, the plea is good in form if it contains averments which either directly negative all the allegations in the bill that give the plaintiff a title to relief against the defendant, or positive averments which destroy the effect of such allegations. The plea is bad in form if the averments of the plea, though true (as on arguing the formal goodness of the plea they are assumed to be), are not a complete answer either by negation or affirmation or both, to all the allegations in the bill which give the plaintiff a title to that which he demands of or against the defendant. The formal badness of such plea is a necessary consequence of the admitted truth of all those parts of the bill to which the averments of the plea do not extend. In order therefore that a plea may be taken as a sufficient answer to the whole bill, it must contains sufficient averments to negative or displace all the allegations in the bill which, if true, gave the plaintiff a title to relief. But inasmuch as a plea is an answer, the defendant must, in addition to the averments, give an answer upon oath to all those statements and charges in the bill upon which he is interrogated, which, if true, would destroy the effect of the matter pleaded; and this is called supporting a plea by an answer, which is generally necessary. If the plea is decided to be good in form, then the truth of the plea alone is in issue between the plaintiff and defendant, and the cause is heard on the issues so joined: just as, in the case where the bill is answered, the cause is heard upon all the issues of law and fact joined by such bill and answer. If a plea is simply overruled, the defendant must answer the bill. If it is overruled, the answer in support of the plea, if there is one, may serve for an answer as far as it goes, and the court may accordingly order it to stand for an answer to such part of the bill, with liberty to except to it or not, according as it may be an insufficient or sufficient answer to that part of the bill to which it extends.

The matter pleaded as an answer to the bill must be one thing, and such a thing as is an answer to the whole of the plaintiff's demand, or to so much of the bill as the plea extends to. The defendant cannot, according to the rules of equity pleading, plead in bar several and distinct matters, any one of which would be an answer to the bill. But if the averments are averments of separate facts which form one material fact, such averments make a good plea; which is thus expressed by Lord Eldon:—"The office of a plea generally is not to deny the equity, but to bring forward a fact which, if true, displaces it: not a single averment, as the averment in this answer, that no bill of sale was executed, but perhaps a series of circumstances forming in their combined result one fact which displaces the equity" (Lord Eldon, *Rowe* v. *Teed*, 15 Ve. 377).

The definition of a plea "not denying the equity, but bringing forward a fact which, if true, displaces it," is in substance the same as the definition of an exceptio by Gaius (iv. 119):—"Omnes exceptiones in contrarium concipiuntur, quia adfirmat is, cum quo agitur."

A defendant may disclaim all interest, right, or title in or to the matter of the plaintiff's bill; but it will nearly always happen that such disclaimer will be an insufficient answer by itself, and that there will be parts of the bill to which it will be necessary to give an answer.

A defendant may demur to a part of a bill as well as to the whole bill: he may also plead to a part of a bill as well as to the whole bill: and he may demur, plead, answer, and disclain, with respect to the same bill. But it is very rare that any two of these ways of pleading are united, except an answer and disclaimer, on account of the practical difficulty attendant on such a mode of defence. For it follows from the nature of these ways of pleading that they must severally apply to substantially different parts of the bill. A man cannot plead to that matter to which he demurs; for to plead is to offer something as an answer sufficient in substance, though it may not be so in form, and to demur is to allege that he ought not to answer. For the same reason he cannot answer, in the formal manner of an answer, to that to which he has either pleaded or demurred, having by pleading already offered something as a sufficient answer, and having by demurrer alleged that he ought not to answer. "A plea or answer will therefore overrule a demurrer, and an answer a plea; and if a disclaimer and answer are inconsistent, the matter will be taken most strongly against the defendant upon the disclaimer." (Mitford, p. 320.)

Pleadings in equity were formerly continued, like pleadings at law, beyond the bill and answer. The plaintiff replied to the defendant's answer by his replication, which is defined to be "the plaintife's speech or answer to the defendant's answer, which must affirm and pursue his bill, and confesse and avoid, denie or traverse the defendant's answer." (West.) Thus if the answer denied the plaintiff's claim as stated in the bill, and suggested or stated some new matter, it was necessary for the plaintiff to make a special reply which was analogous to the defendant's answer. To meet this special replication, the defendant put in a rejoinder, which is defined to be "the answer which the defendant maketh to the plaintif's replication, which must pursue and confirm his answer and not swarve from the same, and sufficiently confesse and avoid, denie or traverse each material part of the plaintif's replication. If the parties be not at issue by reason of some new matter disclosed in the defendant's rejoynder that requireth answer, then may the plaintif surrejoyne to the said rejoynder, and the defendant in like manner to the surrejoynder, if there be cause, which hapneth verie seldome." (West.)

This method of pleading by special replications and rejoinders is now disused, and all the objects of such proceedings are at present attained by the power which the plaintiff has of amending his bill and stating his case in a better form after he has seen the defendant's answer. The disuse of special replications has also led to the practice of frequently stating the plaintiff's case more completely in his bill in the first instance, and introducing numerous charges and suggestions. Thus if the plaintiff anticipates that the defendant may plead to his bill, and so prevent him from obtaining the complete answer which he wishes, he will charge various matters in his bill which will destroy the effect of the anticipated plea, unless the defendant supports his plea by a full answer to such matters.

According to recent practice the plaintiff may at any time after the time allowed for answering has expired, move the court for a decree, in which he relies entirely upon the admissions in the answer to substantiate his own case. If the answer is against him, he must file a replication, by which he joins issue with the defendant, and both sides are at liberty at once to go into evidence to support their several cases.

The form of pleading used in this country is derived from that of the Romans. In Bracton's work, the fifth part, which is entitled 'De Exceptionibus,' occupies the same place in his treatise as the same matter does in the Institutes of Gaius and of Justinian, and the terms used by Bracton are those of the Roman law: indeed, the whole work of Bracton follows the method and order of Justinian's Institutes. A comparison between the Roman and English procedure in equity is made in Gilbert's 'Forum Romanum.'

After the Legis Actiones among the Romans fell into disuse, the mode of procedure was per formulas, the nature of which is fully explained by Gaius (iv. 39, &c.). The Demonstratio was that part of the formula which showed the matter upon which the plaintiff's demand was founded; the Intentio contained the demand; the Adjudicatio gave power to a judex to decide on the matters in dispute; and the Condemnatio empowered him to make a decree in favour of the plaintiff, or to dismiss the defendant, according to the evidence produced before him. The formula was a proceeding in jure, that is, before the prætor, and it contained the instructions to the judex, to whom, according to Roman practice, the investigation of the facts and the ministerial duty of pronouncing the decree were entrusted. The answer of the defendant to the plaintiff's claim was called Exceptio, and exceptiones were either peremptoriæ—in the bar, or dilatoriæ—in abatement. The plaintiff might answer the defendant's plea by his Replicatio, and the defendant might answer the Replicatio by a Duplicatio, to which the plaintiff might answer by a Triplicatio; "and the practice of all such pleadings," says Gaius (iv. 129), "has been sometimes carried even farther than this, owing to the multifarious character of the matters in dispute."

One example may be sufficient as an instance of the Roman pleading. "If an argentarius sue for the price of a thing sold by public auction, the form of the defendant's plea may be a submission to have judgment against him, provided (si) the thing which was purchased has been delivered to him; and this is a good plea (exceptio). But if the conditions of sale were that there should be no delivery till the money was paid, the argentarius may put in a replication to this effect, submitting to the plea, unless (nisi) the conditions of sale were that the thing should not be delivered to the purchaser before he had paid the money" (iv. 126). The words *si* and *nisi*, which are used in this passage, were introduced merely for the purpose of adapting the pleadings for insertion in the formula; for the Condemnatio in the formula was conditional; that is, if so and so is proved, then make such and such a decree against the defendant; and if not proved, dismiss the defendant.

PLEDGE is a thing bailed (delivered for a temporary purpose [BAILMENT]) as a security to the bailee for the performance of some engagement on the part of the bailor. When the pledge is for a debt, more especially where it is given to secure a loan at interest, it is commonly called a pawn. [PAWNBROKER.] In bailments the degree of care required from the bailee varies according to circumstances. When the bailment is for the sole benefit of the bailee, he is bound to use the greatest care, and is excused by nothing but unavoidable accident or irresistible force. When the bailment is for the mutual benefit of bailor and bailee, the latter is bound to take the same care of the thing bailed as a prudent man usually does of his own. When the bailment is for the sole benefit of the bailor, it is sufficient if the bailee keep the goods bailed as carefully as he does his own, however negligent he may be. Different writers on the law of bailments refer the contract of pledge to each of these divisions.

The pledgee is bound to return the pledge and its increments, if any, upon being requested so to do, after the performance of the engagement. This duty is extinguished if the pledge has ceased to exist by some cause for which the pledgee is not answerable. But he is responsible for all losses and accidents which happen after he has done anything inconsistent with his duty as pledgee, or has refused to do his duty. When the full amount of the debt or duty therefore is tendered and refused, and the pledge is detained, the pledge is at the sole risk of the pledgee: so if the pledgee misuse the pledge. In every case where the pledge has sustained injury from the wrongful act or default of the pledgee, the owner may recover damages to the amount of the injury, in an action on the case. By the act of pledging, the pledgor impliedly warrants that the property is his own, and such as he can rightfully pledge.

The contract of pledge may be extinguished by the performance of the engagement for which the pledge was given, or by satisfying the engagement in any other manner, either in fact or by operation of law, as by the acceptance of a higher security without an express stipulation that the pledge shall continue.

If the engagement, to protect which the pledge is given, be not performed within the stipulated time, the pledgee may sell, upon giving due notice to the pledgor. If no time be stipulated, the pledgee may give notice that he requires a prompt fulfilment of the engagement, upon non-compliance with which he may sell.

The possession of the pledge does not affect the right of the pledgee to enforce performance of the engagement, unless there be a special agreement, by which he has engaged to resort to the pledge only, or to look to it in the first instance.

Though the pledgee may sell, he cannot appropriate the pledge to himself upon the default of the pledgor; nor is he at liberty to use it without the permission of the owner, expressed or clearly implied. Such an implication arises where the article is of a nature to be benefited by or to require being used, in which latter case the use is not only justifiable but indispensable to the discharge of the duty of the pledgee. (Story's 'Commentaries on Law of Bailment.')

As to the power of an agent to pledge, see AGENT; and FACTOR.

PLEDGE (Roman). This word formerly denoted a person who was a security for another; but it now denotes a thing which is a security, and generally for a debt.

The chief rules of English law as to mortgaging and pledging are derived from the Roman law, in which however there is no distinction among pledges, dependent on the nature of the thing pledged, whether it was a thing moveable or immoveable, corporeal or incorporeal; and a thing could not be the subject of pledge unless it could be the subject of buying and selling, for the power of selling a pledge was an important part of the creditor's security. A man might pledge a thing either for his own or another person's debt. The terms used in the Roman law to express pledging, and also the thing pledged, are Pignus and Hypotheca. It is properly hypotheca, where there is a bare agreement (nuda conventio) that a thing shall be a security to a creditor for a debt, and the thing remains in the possession of the debtor. The word hypotheca (ὑποθήκη) is Greek, and denotes a thing subjected to a claim or demand. When the thing was delivered to the creditor, it was called Pignus (Isid., 'Orig.,' v., c. 25); and as moveable things would for obvious reasons be most frequently delivered, a notion got established among some Roman lawyers, aided by an absurd etymology (pignus appellatum à pugno, 'Dig.,' 50, tit. 16, s. 238), that the term pignus was applicable only to a pledge of moveable things; and this notion has also prevailed in modern times. The true etymology of pignus seems to be the same as that of pactum. It is generally said that hypotheca corresponds to the English mortgage, and pignus to pawn or pledge; but this is not the case. No ownership was transferred by the Roman hypotheca. The term hypothecation in English law is still used to express the mortgage of a ship or its cargo.

After the time agreed on for payment was passed, the creditor had the right of selling the pledge and of retaining his debt out of the produce of the sale. If the produce of the sale was not sufficient to discharge the debt, he had a personal action against the debtor for the remainder. Originally perhaps he could only have this right of sale by express contract, but subsequently the right to sell (jus distrahendi sive vendendi) was an essential part of the contract of pledge. Though the creditor was not the owner of the thing (dominus), still he could transfer ownership to the purchaser, a doctrine that is only intelligible on the supposition that he sold it as the attorney or agent of the debtor. But the creditor could only sell the thing in respect of the debt for which the thing was pledged, and not in respect of other debts due to him from the debtor, though he might apparently retain the surplus of the sale in his hands as a satisfaction for such other debts. The power of sale was to be exercised pursuant to the terms of the contract; and when there was no agreement as to the form and manner of sale, the law prescribed the mode of proceeding, which the creditor was bound to observe strictly. It was once usual to insert in the contract of pledge a Lex Commissoria, that is, a condition by virtue of which the thing pledged became the absolute property of the creditor, if the money was not paid at the time agreed on. But by a constitution of Constantine ('Cod.', viii., tit. 35) it was forbidden to insert such a clause in the contract. If anything remained over after satisfying the creditor, it belonged to the debtor.

As the pledgor remained the owner of the thing pledged, he could of course sell it, but the purchaser took it subject to the pledge. The creditor who was in possession of a pledge was answerable for any damage that befel it owing to dolus or culpa, that is, fraud or neglect, but he was not answerable for unavoidable loss.

A pledge was determined in various ways; by the destruction of the thing, by the creditor releasing the debtor, by the debtor paying the debt, and in other ways. When the debtor offered the money to his creditor, he was entitled to have the pledge restored to him. This might be obtained by an actio pignoraticia, which was an actio in personam, and also lay for damages done to or sustained by the thing, or for the surplus of the money if the pledge had been sold by the creditor. The creditor had a contraria pignoraticia actio against the debtor for expenses incurred as to the pledge, for any fraud in the matter of the pledge, as passing off base for better metal, and in some other cases.

The Roman law of pledges has been treated by various writers at great length. A compendious view of it is contained in Brinkmann's 'Institutiones Juris Romani,' Slesvici, 1822; in Marezoll, 'Lehrbuch der Instit. des Röm. Rechtes,' Leipzig, 1839; and in Ayliffe's 'Law of Pledges or Pawns,' London, 1732.

PLEDGING, CUSTOM OF, derived from the French *pleige*, a surety or gage. The expression "I'll pledge you," in drinking, is deduced by some of our writers on popular antiquities from the times when the Danes were in possession of England. It is said to have been the custom of that people to seize the moment when a native of the island was in the act of drinking, to stab him with a knife or dagger; whence people could not drink in company unless some one present would be their pledge or surety that they should receive no harm. (Brompton; Sir Richard Baker's 'Chron.;' Henry, 'Hist. Great Brit.:' see also Eric Pontoppidan's 'Gesta et Vestigia Danorum extra Daniam,' vol. ii.)

Others state the custom to have taken rise from the death of King Edward the Martyr, son to Edgar, who, by the contrivance of his step-mother Elfrida, was stabbed in the back as he was drinking.

Brand thought the expression meant no more than that if you took your cup or glass, I *pledge myself to you* that I would follow your example. (Brand's 'Popular Antiquities,' edited by Sir H. Ellis.)

PLEIADES. [TAURUS.]

PLENARTY. [QUARE IMPEDIT.]

PLENIPOTENTIARY. [AMBASSADOR.]

PLETHORA (a Greek word, πληθώρη, *plethôre*, fulness, in which sense it is used by the Greek medical writers) signifies a redundancy of blood. By the older writers the term was used to express an imagined superabundance of any of the fluids of the body; and the terms bilious, lymphatic, and milky plethora, &c., implied the existence of an excess of one or other of those fluids in the blood. Distinctions were also made, and by a few are still retained between plethora from excess of blood, from insufficient capacity of the vessels, from deficient strength, and so on. By the majority of the physicians of the present day however, the term plethora is used only to express that condition in which the quantity of blood and its nutritive qualities exceed that standard which is compatible with present or the prospect of continued health.

Plethoric persons are marked by a florid ruddy complexion, a full hard pulse, a tendency to hemorrhage from the nose or other parts, a frequent sensation of fatigue and weight in the limbs, a disposition to sleepiness, and by being in what is commonly termed good condition. In this degree plethora cannot be regarded as more than giving a tendency to disease whenever any slight occasional cause is applied. In a greater degree however, it produces effects which are in themselves important: the complexion is yet fuller and more florid, the face seems swollen, and the eyes blood-shot, there is pain in the head, with giddiness, ringing in the ears, dulness, heavy sleep, and a sensation as of flashes before the eyes, inability of exertion, constant feeling of fatigue, and frequent palpitation of the heart.

Such a condition, to which some persons seem from birth peculiarly predisposed, may be produced in nearly all by the constant use of very nutritious food, by gluttony or excess in beer, by indolence, or by the insufficiency or suppression of some habitual discharge. Its principal evil is that it renders the person who is affected by it peculiarly liable to acute inflammations and to hemorrhages in important organs, as the brain, in which the latter produce apoplexy. To avoid such consequences, a less nutritious diet, abstinence from exciting drinks, and the regular employment of active exercise are commonly sufficient; but in more advanced and in extreme cases of plethora, blood must be drawn freely both from the arm and from the neighbourhood of any organ in which there seems a peculiar disposition to its accumulation, or from which it was once habitually discharged; active aperients should also be administered, and the diet should be reduced to a much lower scale than that which had the chief share in engendering the disorder.

PLEURISY (*Pleuritis*), a word derived immediately from the French *Pleurésie*, which comes from the Greek πλευρῖτις, and this again from πλευρὸν, *the side*, which is defined by Rufus Ephesius ('De Corp. Hum. Part. Appell.,' pp. 30, 51, ed. Clinch) to mean πᾶν τὸ ὑπὸ τῇ μασχάλῃ, "all that part which is under the arm-pit."* As this is one of the diseases of which both the nature and the treatment were understood by the ancients almost as perfectly as by ourselves (except of course that they had not the assistance of auscultation and percussion to help them in forming their diagnosis), it may be as well to give in their own words those passages which have been repeated with more or less alteration by every succeeding writer on the subject, omitting those which are either erroneous from their less accurate knowledge of anatomy, or which rest only upon some fanciful theoretical speculation, and adding whatever may be necessary to bring the article as far as possible up to the level of the present state of medical science.

"Pleurisy, properly so called," says Paulus Ægineta (*loco cit.*, in Mr. Adams's translation, 8vo, London, 1834), "is an inflammation of the membrane which lines the ribs, and is attended with difficulty of breathing, cough, continual fever, and pain shooting to the clavicle and hypochondrium," which definition agrees with that given by Galen ('De Loc. Affec.,' lib. v., cap. 8, p. 326, ed. Kühn; 'Ad. Glauc. de Med. Meth.,' lib. ii., cap. 1, p. 77; 'Introd.,' cap. 13, p. 734; 'Definit. Med.,' § 264), Aretæus, Aëtius, and Alexander Trallianus (*locis cit.*). The disease has been variously divided by different writers; Dr. Good ('Study of Med.') mentions the three following varieties:—1, *Pleuritis vera*, True Pleurisy. Fever, a cauma; pain felt chiefly on one side, the inflammation commencing in that part of the pleura which lines the ribs. 2, *Pleuritis mediastina*, Pleurisy of the Mediastinum. Heavy pain in the middle of the sternum, descending towards its ensiform cartilage; with great anxiety; the inflammation, from its symptoms, being obviously seated in the mediastinum. 3, *Pleuritis diaphragmatica*, Pleurisy of the Diaphragm. Painful constriction around the præcordia; small, quick, laborious breathing; manifesting that the inflammation is seated chiefly in the diaphragm. He adds, however, that the subdivisions lead to nothing of practical importance, as the causes are nearly alike, and the same mode of treatment is applicable to the whole. A more essential distinction is that adopted by Dr. Law ('Cyclop. of Pract. Med.'), namely, acute and chronic, and this will be followed here, because it seems almost impossible to treat either of the nature or the treatment of these two forms of pleurisy under one and the same head.

In acute pleurisy, says Aretæus (*loco cit.*, in Dr. Reynolds's translation, 8vo, London, 1837), "we have acute pain in the clavicular region, together with a sharp burning heat; the recumbent posture is easy on the inflamed side, because there the membrane remains in its place, but to lie on the opposite one is exceedingly painful, and from the weight, inflammation, and dragging, the pain extends through the whole continuity of membrane to the shoulders and clavicles, in some even to the back and shoulder-blades. To this succeed dyspnœa, watchfulness, loathing of food, bright redness of the cheeks, a dry cough, difficult expectoration. To this description it may be added, from Paulus Ægineta, that "the pulse is hard and serrated;" and it should be noticed that the *decubitus*, or position of the patient, mentioned by Aretæus and repeated by numerous modern writers, is not constant, and therefore cannot be exclusively relied upon as a diagnostic sign, for it is sometimes observed that the aggravation of the acute lancinating pain caused by the pressure when lying upon this side, makes the patient seek a more easy position either upon the opposite one or upon the back.

With respect to the diagnosis of pleurisy, it may be distinguished from hepatitis, says Paulus Ægineta, by the pain in pleurisy being pungent, and the cough being sometimes without expectoration and sometimes with it, and by the pulse being hard and serrated; while in inflammation of the liver the pain is not pungent, nor is the pulse so hard, and the cough throughout is dry and without expectoration, and the face appears pale. (Compare Alex. Trall., *loco cit.*) It may be distinguished from inflammation of the external muscles, or pleurodynia [PLEURODYNIA], by the latter affection being (according to the same author) unaccompanied with cough and expectoration, nor is the pulse hard. From pneumonia it is hard to distinguish it without calling in the aid of auscultation and percussion; and indeed Dr. Cullen, in his 'Practice of Physic,' has treated of both these affections under one common definition. It may however be observed (with Dr. Good) that in pleurisy the face is comparatively but little flushed, and far less tumid than in pneumonia; that the pulse is harder, and that the seat of the pain is fixed, while in pneumonia it shifts not only to different parts of the same side, but often from the one side to the other. The characteristic cough of pleurisy (as distinguished from that which follows pneumonia) is a short cough, either dry from the beginning to the end, or accompanied with a thin mucous expectoration; should the sputa be more abundant, or deviate from this character, we may suspect a complication either of pneumonia or bronchitis. The cough, however (adds Dr. Law), is often wanting altogether, or is so slight as to attract the attention of neither the patient nor physician. For the characteristic signs of pneumonia derived from auscultation and percussion, the reader must see the article LUNGS, DISEASE OF THE, while only those relating to pleurisy will be given here. Upon auscultation, the inspiration will appear feeble, distant, or inaudible, but will be restored by change of posture. *Ægophony* will exist when the quantity of fluid effused is no more than forms a thin layer between the lungs and parietes of the chest. The *bruit de frottement*, or *sound of friction*, will be heard when there is partial albuminous exudation, with little or no effusion of serum. Upon percussion, there will be more or less of sound, with moderate resistance, decreasing from below upwards; and this dulness will be diminished or removed by change of position. It was in cases of pleuritic effusion that Hippocrates proposed the succussion, or shaking of the chest, as a means of assisting the diagnosis ('De Morb.,' lib. i., p. 178, ed. Kühn; *ibid.*, lib. ii., pp. 256, 258; 'Coac. Prænot.,' p. 306;

---

* The word πλευρῖτις is generally said to be derived from πλευρὴ, *the pleura*, but (as far as the writer is aware) the word πλευρὴ is never used by the ancient medical writers in that sense. That which is called *the pleura* by modern anatomists is called ὑπεζωκὼς ὑμὴν, or simply ὑπεζωκὼς by Aretæus ('De Caus. et Sign. Morb. Acut.,' lib. i., cap. 10, p. 20, ed Kühn), Aëtius (lib. viii., cap. 76, p. 175, B., ed Ald.); Alexander Trallianus (lib. vi., cap. 1, p. 85, ed. Steph.), and Paulus Ægineta (lib iii., cap. 33, p. 41, B., ed Ald.). Galen uses the same word in more than one place, and with regard to its meaning says ('De Anatom. Administr.,' lib. 7, cap. 2, p. 591, ed. Kühn), "As the other membrane is called the peritonæum (περιτόναιον), because it is extended around (ἀπὸ τοῦ περιτετάσθαι) the alimentary vessels, so this (that is, *the pleura*) is called ὑπεζωκὼς, because it fastens together internally (ἔνδοθεν ὑπέζωκε) the whole of the ribs."

'De Loc. in Hom.,' pp. 123, 124); but it is now known that no sound can be heard unless air be present in the chest at the same time—that is, unless empyema be combined with pneumo-thorax, which is a rare occurrence.

With respect to the anatomical characters of pleurisy, they agree with what may be observed in inflammation of all serous membranes, and consist partly in morbid alterations of the pleura itself, and partly of the secreted fluid. Inflammation of the pleura, says Laennec, is always accompanied by an extravasation on its internal surface; the matter effused being either coagulating lymph termed a *false membrane*, or else serosity, or a sero-purulent fluid. The false membrane, or exudation of lymph, is gradually changed into cellular substance, or rather into a true serous tissue, like that of the pleura. The serous effusion is absorbed, the compressed lung expands, and the false membrane investing it and the pleura costalis become united into one substance, which afterwards becomes vascular and organised, and constitutes permanent adhesions. A severe pleurisy that has terminated by numerous adhesions, renders the part so affected much less liable to subsequent attacks of the same disease; and when it occurs, the inflammation and effusion do not extend to the adherent parts.

Among the occasional causes of pleurisy, enumerated by Laennec (after Celsus), are,—long exposure to cold after violent exercise; metastasis of gout, rheumatism, and cutaneous diseases; blows on the chest; and fracture of the ribs. "The winter season," says Aretæus, "is most liable to produce this disease, and next to it the autumn; the spring is less so, unless it chance to be a cold one, while the summer is the least so of all." In reference to the period of life, he remarks that old people are more liable to it than those who are in the prime of life, and these again than children. Among predisposing causes, Laennec mentions a slender frame, narrowness of the chest, the immoderate use of spirits, and tubercles in the lungs.

Pleurisy terminates either in resolution, suppuration, or gangrene. The former is the ordinary and most favourable issue. The last occurs rarely, and Laennec has seen only one instance of it from acute inflammation. Suppuration, however, is by no means uncommon, in which case, says Aretæus, "shivering fits ensue, and lancinating pains, accompanied with a desire to sit in an upright posture; the breathing gets worse, and there is great fear lest the lung, by suddenly drawing in the purulent matter, should produce suffocation, after the previous and greater danger has been escaped: should the matter, however, burrow between the ribs and separate them, and either point externally or burst into the bowels, the patient usually recovers."

With respect to the treatment, perhaps there is no disease in which profuse bleeding from a large orifice has been so generally recommended by practitioners of all ages and all nations; the only question which has ever arisen upon the subject being, whether the blood should be taken from the side affected, or from the opposite. Hippocrates, and most of the earlier Greeks, recommended the former, while the latter method was practised by Archigenes ('ap. Aëtium,' tetrab, ii., serm. 4, cap. 68), Avicenna ('Canon.,' lib. iii., fen. 10, tract 5, cap. 1), Avenzoar ('Teisir,' lib. i., tract 16, cap. 3, p. 23, D., ed. Venet., 1549), and their followers in the middle ages. The dispute, which is one of those that have been settled by the discovery of the circulation of the blood, was before that time (as may easily be imagined) considered to be of the greatest consequence, and at the beginning of the 16th century raised a kind of civil war (as Bayle says) among the Portuguese physicians on account of the controversy between Denys and Brissot, the particulars of which are too curious to be altogether omitted. The dispute was brought at last before the tribunal of the university of Salamanca, where it was canvassed in a most profound manner by the body of physicians; but in the meantime the partisans of Denys, who were the more powerful, obtained a decree from the civil authorities forbidding physicians to bleed on the same side on which the pleurisy was. At last the university of Salamanca gave judgment, and decided that Brissot's opinion was the pure doctrine of Hippocrates and Galen. The other party removed the cause before the Emperor Charles V., 1529, and were not satisfied with exclaiming against the doctrine of Brissot as false, but declared it to be impious and deadly, and that it was no less pernicious to the body than Luther's schisms to the soul. Unluckily for them, just about this time Charles III., duke of Savoy, happened to die of a pleurisy, after having been bled pursuant to the practice which Brissot had opposed. This put a stop to the appeal to the emperor; but books were written on the question in all parts of Europe, and the practice of the Arabians was generally condemned. A list of these treatises is given by René Moreau, in the Life of Brissot, prefixed to his edition of his work 'De Incisione Venæ in Pleuritide Morbo,' &c., Paris, 1622, 8vo. (See Bayle, art. 'Brissot,' from whom the above account is abridged.) But after all this absurd discussion, there are some cases of pleurisy that will not bear bleeding, and the lancet is now much less had recourse to than formerly.

Besides blood-letting, which may assume the form of cupping and leeches, the usual antiphlogistic remedies, such as saline diuretics, diaphoretics, purgatives, mercurials, blistering, &c., may be employed; in cases of acute pleurisy, the operation of paracentesis thoracis is very seldom had recourse to, and is hardly ever attended with more than a temporary relief.

Chronic pleurisy is either the continuation, as it were, of the disease in its acute form, or else exhibits at no period either the intense fever, the violent pain, or energy of reaction which characterises an acute disease. In this latter form it creeps on very insidiously, without much acceleration of pulse or heat of skin; the pain in the side amounts to no more than a mere soreness; and the difficulty or hurry of breathing is sometimes so inconsiderable as not to attract the individual's attention. However, his unhealthy pallid appearance, his loss of appetite, and languid look, emphatically tell of mischief going on; and upon close examination it is found that the absence of fever is not constant, but that towards evening there is a febrile movement.

The anatomical characters of chronic pleurisy do not differ very widely from those of the acute form, especially when it has been a mere transition of one form of the disease into the other. The fluid effused, however, partakes more of a purulent character, and the false membrane is firmer and more condensed, owing perhaps to the longer time it has been under the pressure of the effused fluid. The lung too is more compressed than in acute pleurisy, so much so that there is sometimes a complete annihilation of its vesicular structure, and the organ itself is reduced to a thin lamina, not exceeding six lines in thickness, lying down along the spine.

The prognosis of chronic pleurisy is, generally speaking, very unpromising: in the ordinary course of the disease a slow wasting fever sets in; there is a gradual emaciation; the appetite fails; the pulse is languid, although not much quickened; the legs swell, and the face becomes puffed; the expectoration often has a disagreeable alliaceous smell. Under these symptoms well-defined hectic fever soon supervenes, and rapidly wears down the patient.

The treatment of chronic pleurisy differs (as might be supposed) very materially from that of the acute form of the disease. Blood-letting is hardly ever resorted to, for the weakened habit of body will not bear the exhaustion of it. For promoting the absorption of the effused fluid, as well as for preventing its further secretion, external applications, comprehending the different modifications of counter-irritation, for example, blisters, setons, issues, stimulating liniments, &c., appear to be most efficacious. In some cases however the operation of paracentesis thoracis seems to be the last resource, and this so often fails that it is by some practitioners considered an almost hopeless experiment. In trying to improve the habit of body and to relieve the constitutional symptoms, which most commonly accompany this form of the disease, recourse must be had to a nutritious but not a heating or exciting diet, and to the cautious exhibition of such tonics as the patient is able to bear. Change of air is often productive of the most decided benefit, and sometimes effects an almost instantaneous amelioration in the symptoms, by causing the night perspirations to cease, the appetite to improve, and the sleep to become refreshing.

A very complete list of works on the subject of Pleurisy is given in Ploucquet, *Literatura Medica Digesta*, 4 vols. 4to, Tübing., 1808-9; and a selection in the Appendix to the *Cyclop. of Pract. Med.*

PLEURITIS. [PLEURISY.]

PLEURODYNIA (from πλευρά, the side, and ὀδύνη, pain—pain of the side), called also "false pleurisy." The term includes all those pains of the sides which are unconnected with pleuritic inflammation, whether arising from a rheumatic affection of the intercostal muscles, neuralgia in the same parts, or any other cause not evidently pleuritic. It is a matter of great importance to distinguish pleurodynia from pleuritis, as the treatment of the one is frequently diametrically opposite to the other. Pleurodynia may arise from a rheumatic or gouty tendency of the body, producing derangement of the respiratory muscles, and in these case the remedies for rheumatism and gout must be applied. When the pain arises from pure neuralgia, the treatment must be adapted accordingly. In hysterical and anæmic cases iron should be given, but in the form of paladal neuralgia, quinine is the great remedy.

PLICA POLONICA is the name given to a disease which is chiefly remarkable for the sticking together and matting of the hair, and which is peculiarly frequent in Poland: a few examples of it have been met with in Tartary, among the lower orders of the Russians, and in Hungary, and fewer still in Switzerland and France.

The disease chiefly affects the scalp; the hair grows to an unusual length, is matted together by a sticky and most offensively-smelling secretion, and is commonly infested with vermin. Indeed, the symptoms of the disease, as far as the hair is concerned, are only those which would result from excessive neglect of cleanliness; and hence many who have seen numerous cases in Poland, believe that they are only produced by the dirty habits of those affected, who, it is well known, if the disease do not spontaneously make its appearance, spare no pains to produce it. So great is the prejudice in favour of Plica entertained by the lower order of Poles, who regard it as affording a certain security from all other sickness and misfortunes, that they will through their whole lives endure the inconvenience and misery of carrying about huge masses of filthy stinking hair many feet in length, rather than submit to the removal of it, which is necessary for their relief.

The hair of persons affected with *Plica Polonica* has been carefully examined under the microscope, and Gunsberg and Von Walther have both described the cells of fungi belonging to the genus Trichophyton. The parasite as described by Gunsberg consists of articulated filaments surrounded by innumerable spores of very minute size. The changes in the hair produced by this parasite consist in the thickening of the root of the hair, a spindle-like enlargement of the longitudinal cylinder of the channel of the hair, through the constant piling up of new masses of fungi in it, in the splitting and parting of single hair fibres, which gives at last to the hair the appearance of a brush, or of a hedgehog skin, at the point through which the spores of the fungus pass. The epithelium or cells of the hair are very much condensed, and the hair cylinder frequently altogether disappears. In the adhesive mass are found a great many large epithelial cells with small granular bodies, resembling the exudation corpuscles of inflammation. Von Walther attempted to inoculate *Plica Polonica*, but did not succeed.

Herr von Studzienski, a Russian, has recently written on the Plica, and endeavoured to show that it was only an intense form of the natural condition of moulting. This view however is not supported by the facts of the case, and no one can doubt its specially morbid nature, after such researches as those of Von Walther and Günsberg.

The only treatment which is known to be constantly beneficial is the removal of the hair, and strict cleanliness; other means must be decided in each case by the general state of the patient's health. The popular notion entertained in Poland, that dangerous diseases will follow the cutting of the hair, is entirely without foundation.

(Kuchenmeister on *Animal and Vegetable Parasites*, translated by Lankester, 1847.)

PLINTH. [COLUMN.]

PLOMBAGIN. A bitter non-azotised principle of unknown composition, contained in the root of the *Plumbago europæa*. It crystallises in orange-yellow needles of an astringent saccharine taste, volatilises by heat without change, and is slightly soluble in cold water, more so in hot, and readily so in alcohol and ether. Alkalies communicate to the aqueous solution a fine cherry-red colour.

PLOTTING. [SURVEYING.]

PLOUGH. That the plough is an instrument of the highest antiquity is apparent both from the oldest writings that we possess and from the existing monuments of Egypt. We might exercise our imagination in supposing a probable origin of the plough in the branch of a tree dragged along the ground, in which the stump of a smaller branch made furrows as it went on. It seems indeed probable that some accidental circumstance first suggested this mode of stirring the earth to prepare it for receiving the seed.

The oldest forms of the plough of which we have any description in ancient authors, or which are represented on monuments and coins, are very simple: a mere wedge, with a crooked handle to guide it, and a short beam by which it was drawn, form the whole instrument. The light Hindu plough, now in use in many parts of India, seems to differ little from the old model.

Before we enter into any details it may be as well that we describe the different essential parts of a plough, by the names which are usually given to them.

The body of the plough is that part to which all the other parts are attached. The bottom of it is called the *sole*, or *slade*, to the fore part of which is affixed the *point*, or *share*; the hind part of the sole is called the *heel*. The *beam*, which advances forward from the body, serves to keep the plough in its proper direction, and to the end of it are attached the oxen or horses which are employed to draw it. Fixed in the beam, in a vertical position, before the point of the share, with its point a little forward, is the *coulter*, which serves to cut a vertical section in the ground, while the point of the share, expanding into a *fin*, separates a slice by a horizontal cut from the subsoil or solid ground under it. The *mould-board* or *turn-furrow*, is placed obliquely behind the fin, to the right or left, in order to push aside and turn over the slice of earth which the coulter and share have cut off: it thus leaves a regular furrow wherever the plough has passed, which furrow is intended to be filled up by the slice cut off from the land by the side of it, when the plough returns. The stilts or handles, of which there may be either one or two, as is thought more convenient, direct the plough by keeping it in the line required and at a regular depth in the ground. The single stilt appears to be the most ancient form.

Wheels are a modern invention in comparison with the other parts. They support the end of the beam, and prevent it from going too deep into the ground while the plough is going on. The greatest improvements introduced into modern ploughs are in the shape of the mould-board, or turn furrow, of which we shall take particular notice, and the contrivances for regulating the line of draught, so as to make the plough go at an equal depth, and cut off a regular slice of equal breadth, without any great force being applied by the ploughman who holds the stilts.

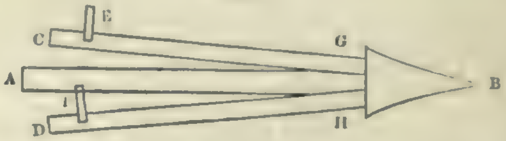
The Hindu plough consists of a slight beam, often without any coulter, a narrow share, and a corresponding stilt. The whole is of wood, slightly pointed with iron. It is so light that a man can readily carry it upon his shoulder. When it is at work it is usually drawn by a small buffalo, and sometimes by a man or a woman. This instrument is intended merely to make a shallow furrow in a very light soil, or in the mud produced by irrigation where rice is cultivated. It does not act as our ploughs do, nor does it turn over a regular furrow, but it acts more like one of the tines, or teeth, of some of our more complicated instruments called cultivators or grubbers, with which the earth is stirred without being turned over.

The Chinese plough resembles the Hindu in its simplicity. The earth is turned over by holding the instrument obliquely, and much depends on the art of the ploughman, in whose hands it is like a stout shovel pulled through the ground by a horse or an ox. The sole is not straight, but rounded, like the bottom of a boat. The work done by this instrument is not unlike the furrow drawn in the sand at the bottom of the sea when a ship drags her anchor.

The ploughs in use in different countries in Europe underwent little change for many centuries; it is only lately that any attempt has been made to vary the old forms.

The Roman plough, such as is described by Virgil in the 'Georgics' (i. 174), is still used in many parts of France, under the name of *Araire Romain*. It consists of a beam (*temo*), a body (*buris*), a share (*vomer*), and a handle or stilt (*stiva*). The office of the turn-furrow is performed by two pieces of wood about six inches long projecting obliquely upwards, and very properly called teeth (*dentalia*) E F (*Fig.* 1). The sole of the plough A B has two pieces of wood C G and D H fixed to it on each side, forming an acute angle with it, in which the teeth are inserted. This exactly answers the description of Virgil, "Duplici aptantur dentalia dorso" (the teeth are fitted to the double back).

Fig. 1.



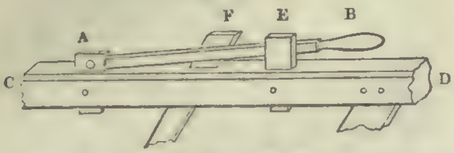
These teeth help to push aside the earth to the right and left, and the instrument resembles what is called a moulding plough, which is used in throwing the soil aside against young plants growing in rows, as turnips, potatoes, &c. A chain or pole connected with the end of the beam was hooked to the middle of the yoke on the neck of the oxen, and thus the plough went on making parallel furrows, so near to each other that the preceding furrow was partially filled with the earth which the dentalia pushed aside. The point was in the shape of the head of a lance. This plough might suffice in light mellow soils, which had been long in cultivation, and had more the texture of garden mould than of stubborn clay.

The small double mould-board plough, common in other parts of France, is evidently taken from this. The teeth not being sufficiently strong, a slanting board was substituted on each side, and wheels were added, to diminish the labour of the ploughman. The stilt remained the same at the place where it is attached to the plough, but higher up it was divided into two, like a fork, for the convenience of holding it with both hands. This plough acts exactly like the other, but it is stronger and better adapted for heavier land. Neither of them goes much deeper than four or five inches, leaving shallow parallel ridges, in which the seed falls, and is buried by light wooden harrows, which are drawn over the land after sowing. This is an imperfect tillage, the bottoms of the furrows being only partially stirred. The broad flat share, and the single mould-board which turns the earth completely over, after lifting it up, is a far more effectual instrument, and has been adopted wherever agriculture has made any improvement. This plough more nearly imitates the digging with a spade; and the more perfect the imitations, the better is the work.

The mould-board of a modern plough is either fixed on one side, or made so as to be shifted from one side to the other. In the first case half the furrow-slices lie on one side and half on the other, and there is of necessity a double furrow where they join. When it is desirable that the surface should be quite flat, and the furrow slices all in one direction, the mould-board must be shifted at every turn, and a plough which admits of this is called a turn-wrest plough.

It is evident that the mould-board of a turn-wrest plough must be so constructed as to act with either side uppermost; it can therefore have only a very slight convexity to push over the slice cut off by the coulter and share; and a considerable force is lost by the obliquity of the action in doing so. The share of this plough is pointed like a lance, or presents a flat edge like a broad chisel, according as the soil is light or heavy. The point of the coulter is placed in line with that side of the point which is nearest to the unploughed land, and this is done by means of a piece of wood A B (*Fig.* 2), which presses it against one side or the other of the mortice in which it is placed in the beam C D, by changing the position of the pieces A B to the other side of the projection E on the beam, and pressing the head of the coulter F to the other side. The mould-board has a hook at the fore part, which goes into a staple in the side of the fore part of the body of the plough towards the preceding furrow: a piece of wood on the inside of the mould-board keeps it at the proper angle with the line of the sole.

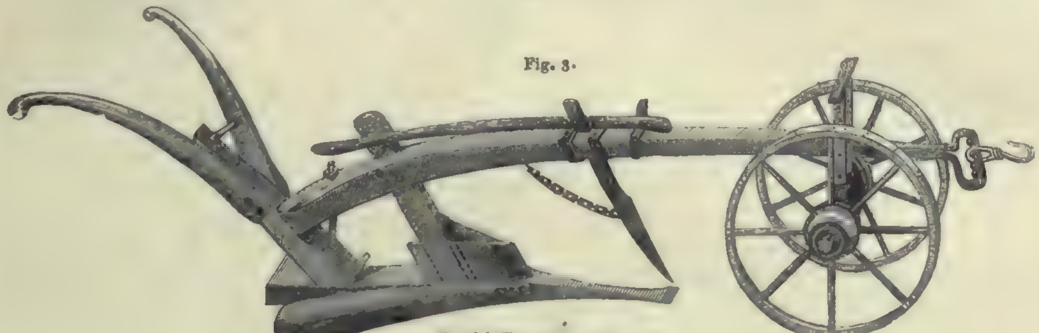
Fig. 2.



The defect of this plough, which is roughly represented below, is in its weight and clumsiness more than in the shape of the mould-board; for when it is made lighter, it is not so bad a construction as appears at first sight, and it does its work very neatly in heavy loams with a dry subsoil. If, instead of one mould-board, two were used alternately, of a better shape for turning over the furrow-slice, this plough would be much improved; and this plan is adopted in many other forms of the turn-wrest plough, as in that made by Cousins, of Southmolton.

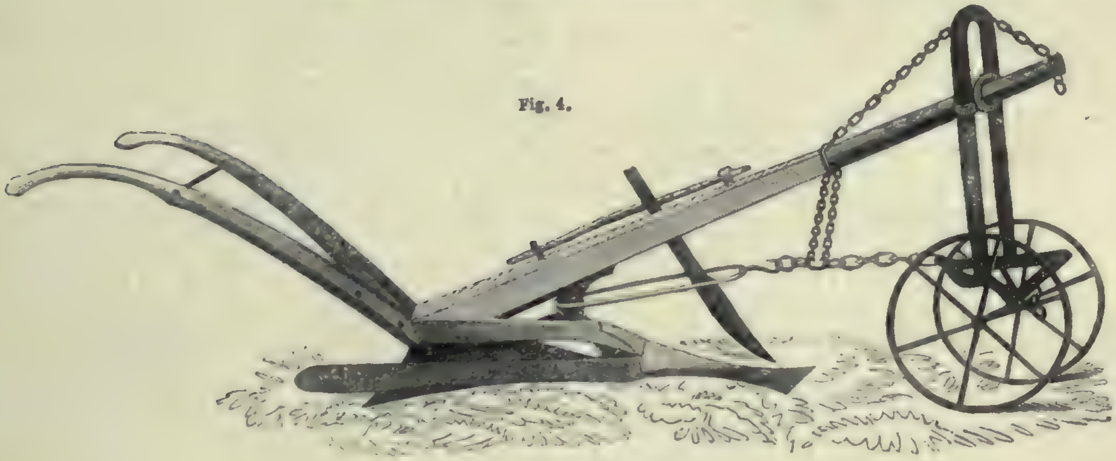
The form of the turn-furrow is of material importance, for on this depends not only the perfection of the work, but also the lightness of the draught. When we follow a plough working in a mellow soil which slightly adheres to the plough, we often perceive that, instead of being turned aside, the earth is carried forward, and only falls off when the accumulation of it becomes heavy enough to overcome the adhesion. It does not slide off from the mould-board itself, but separates from the earth which adheres to the latter; thus showing that the shape is defective, and giving good hints for its improvement. But as the same plough will sometimes turn over the same earth better when it is either drier or moister, it is very difficult to determine, by experiment only, what may, on the whole, be the best shape. A little reflection and the application of scientific principles may greatly assist us here. It is not sufficient however to find the curve which will make the plough go through the ground with the least force. The plough must also perform its work perfectly, and if anything is to be sacrificed, it is better to employ more power than to plough the ground badly. After having ascertained the mechanical principles which bear on the working of the plough, we must observe its action carefully, follow the plough day after day, in different soils and different weather, and thus we may be led to observe all the circumstances which attend its operation, and correct any mistakes which an erroneous theory might have led to.

Fig. 3.



Kentish Turn-Wrest Plough.

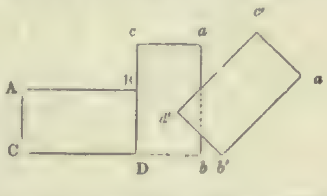
Fig. 4.



Ransome's Kentish Turn Wrest Plough.

Many attempts have been made to ascertain the exact curve which the turn-furrow should have to perform the work well and at the same time to produce the least resistance. The difficulty of the problem lies in determining the data, or principles on which the investigation is founded; and these are so various, that it is not surprising that no very satisfactory conclusion has yet been obtained. We will make an attempt at a solution from a simple examination of the motion to be produced in the portion of earth to be turned, which we will call the furrow-slice. We shall suppose this separated from the adjacent soil by the vertical cut of the coulter, and at the same time from the subsoil by the horizontal cut of the share; a section of the slice, by a plane at right angles to the line of the ploughing, will be a parallelogram A B D C (*Fig.* 5), the depth, A C, being the thickness of the slice, and A B its width. Confining our attention to this section of the slice, the object is to move it from its position A B D C, as cut off by the coulter and share, to that of $b' d' c' a'$, where it is inclined at an angle of 45° to the horizontal line; the surface, A B ($b' a'$), being laid on the slice previously turned over, so as to bury the grass or weeds which might be rooted there, exposing the roots to the sun and air. The more uniformly this motion is produced, and the more regularly the successive sections follow each other, the less power will be required to turn over the whole slice. The motion of C D round the point D must therefore be uniform. If the turn-furrow is horizontal at the point where it joins the share, and of the same width as the furrow-slice, it will slide under the slice; and if the vertical sections of its upper surface, at equal distances from the share, are inclined at angles regularly increasing with this distance till it arrives at the perpendicular, the turn-furrow will, as it advances, turn the slice from a horizontal to a perpendicular position: the section of it will then be D c a b. The inclination of the section of the turn-furrow must now be to the other side, forming an obtuse angle with the section of the sole, until it has pushed the slice over at the required inclination of 45°, which theory and experience have shown to be the best adapted to expose the greatest surface to the action of the atmosphere, and likewise to form

Fig. 5.

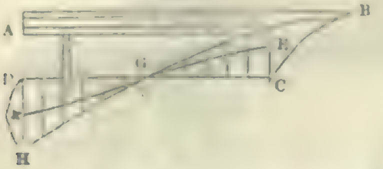


the most regular furrows for the reception of the seed, which the harrow can then most readily bury.

The surface of this turn furrow is curved in the form of the spiral thread of a screw, such as would be generated by a line (H D in the following figure) about 9 or 10 inches long, and either straight or slightly curved, moved uniformly forward in a direction at right angles to its length, while it revolved uniformly round one of its extremities for 3 or 4 feet, commencing with the horizontal position, and terminating in an angle about 45° beyond the vertical. The curve thus generated will be found to turn over soils of a moderate tenacity very perfectly. If it is very light, the surface may be formed by arcs of circles with a considerable diameter, the concave part upwards; if it is very tenacious, the convex part of the arches may be upwards. The annexed figures (6, 7, 8, 9) will explain this. The distance of the perpendicular F G from the fin of the share may also be varied, either lengthening or shortening the turn-furrow, as experience may show to be most advantageous.

Horizontal Plan of the Plough.

Fig. 6.



A B, the Sole; C, the Fin; D C, the bottom of the Turn-Furrow; E C and H D being the revolving line traversing the distance C D, and shown in its various positions by the transverse lines.

Sections of the three different turn-furrows at different distances from the heel.

Fig. 7.

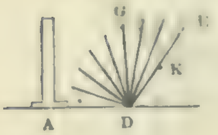


Fig. 8.

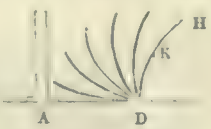

Fig. 9.

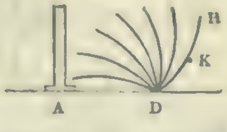


A plough was constructed on this principle by Messrs. Ransome, of Ipswich, at the suggestion of the writer of this article (the late Rev. W. Rham), and exhibited at the meeting of the Royal Agricultural Society of England, held at Cambridge, July 15, 1840. In soils of a loose mellow nature it answered completely, and did the work more perfectly than any other plough. It united the parallelism of the sole and bottom of the turn-furrow of the Flemish plough with the improved shape of the turn-furrow. By adopting the variations in the shape of the turn-furrow which we have suggested, this plough may be adapted to any soil, and be used with or without wheels.

Ploughs were formerly made of wood having those parts covered with iron where the greatest friction takes place, the share and coulter only being of iron; but in consequence of the greater facility of casting iron in modern times, it is now made wholly of this metal. The advantages of iron are, its durability, and the smaller friction it occasions when once polished by use. The inconveniences are, the additional weight of the instrument, and consequent greater friction of the sole, which experiments have proved to be greater than was generally suspected. A great improvement has been introduced by making the points of the shares of cast iron, which, by a mode of casting the lower surface on a plate of metal, makes one surface much harder than the other; and as the softer surface wears more rapidly, a sharp edge is always preserved.

The different parts of a plough are now usually cast, so that if any one fails or wears out, it can be instantly replaced by moving a few screws or bolts. This is a very great saving of time and expense; for before this, every time an accident happened to any part of the plough, it took a long time to repair it, and in the meantime the labour was suspended, often at a very critical time of the year. There is another advantage in having the essential parts of cast-iron. If any particular shape has been once discovered to be the best for any part, that shape is preserved without deviation in every plough made on the same pattern, and with respect to the turn-furrow this is of the greatest importance.

Where the soil is light and crumbling, without stones, as in Norfolk, a single handle or stilt is sufficient; but where some force is occasionally required to prevent stones or other obstacles from turning the plough out of its course, two stilts are most convenient, placed at a more obtuse angle with the sole of the plough.

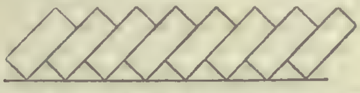
The force required to draw a plough depends not only on the nature of the soil, but also on the shape of the plough, and especially on the position of its different parts with respect to each other, so that they do not counteract each other.

If a plough were drawn in the direction of the sole, the obliquity of the turn furrow would cause it to turn towards one side, and it would require a considerable force to keep it straight. In order to prevent this, the line of draught is placed at an angle, which varies with that of the turn-furrow and the force required to push the furrow-slice over. To adjust this angle, so as to cause the plough to keep in the intended line, there is a contrivance at the end of the beam to change the position of the ring by which the plough is drawn to the right or left of the line of the beam, and another by which it may be raised or lowered. By this device the plough may be drawn from a point on either side of the beam, and higher or lower as may be required. When the plough is found to *take too much land*, as ploughmen say, that is, tends to increase the width of the slice cut off by the coulter, the bridle is shifted to the left by moving the pin into another hole: when it goes *out of the land*, as it is called, that is, diminishes the width of the furrow-slice, the pin is moved a hole or two to the right, until the plough has no tendency to deviate to either side. If it inclines to rise out of the ground, the ring is shifted in the iron bridle and placed in a hook or notch higher up; if, on the contrary, it dips too deep, the ring is hooked lower. Thus a plough may be made to go straight and at a regular depth, without any more force being applied to the stilts than is required to counteract inequalities in the land, or accidental obstacles, such as stones or roots, which might throw the plough out of the ground. When the soil is of unequal texture, it is useful to have a small wheel connected with the fore part of the beam, so as to prevent its dipping downwards, which would require a great pressure on the stilts to keep the point of the share up, and thus increase the friction of the sole on the ground, and consequently the labour of the horses. In other cases, ploughs are provided with two wheels connected with the beam, one of which runs in the furrow to the right, and the other on the unploughed soil to the left. When the plough has been well adjusted, and the larger wheel runs in the angle of the furrow, it acts as a gauge to regulate the width of the slice as well as its depth: in very uniform soils without stones, the plough, when set in the proper direction, will make a very straight and even furrow parallel to the one in which the wheel runs, without any person holding the stilts; so that all that is required is to turn the plough at the end of each furrow, and set it in to the proper line to form the next. As this admits of very correct adjustment, no unnecessary force is required to draw the plough: and hence this plough appears to be the easiest for the horses; and if the wheels are not very heavy, and the plough is of a good form, it certainly requires less power to move it than many which are without wheels; and it is far superior to the old clumsy wheel plough, the beam of which rests on a heavy carriage, without being firmly attached to it. This, instead of lessening the draught, increases it by all the pressure of the beam upon the carriage, besides the weight of this last and of the wheels. There are some very irregular and stony soils, where a common swing plough can scarcely be kept steady without the help of wheels, and where it would not be so convenient to have the beam fixed on the wheels. In this case a separate carriage is necessary, that the ploughman may have a fulcrum on which he can raise his plough, or turn it to either side to avoid any considerable stone or other obstacle. Wheels have this advantage: they will enable an inferior ploughman to make better work than he could possibly do without them; and that too with less labour to the horses; because, from his want of skill, the swing-plough would be continually subject to sudden deviations, requiring him to use his strength to counteract them; and each exertion of the ploughman adds to the labour of the horses.

Without entering into any comparison of ploughs differently constructed, it is evident that the shape of the plough must vary with the nature of the soil which it is to turn up. A light soil must be shovelled up; a mellow one may be turned over with any kind of mould-board; a very stiff tenacious soil which adheres to any surface pressed against it, will be more easily turned over by a few points of contact which do not allow of adhesion. Hence the point and turn-furrow have been made of all imaginable shapes, and while one man contends for a very concave form, another will admit of nothing which is not very convex. That plough will no doubt have the least draught which is best suited to the soil which it has to move. The lighter the plough is, consistently with sufficient strength, the less draught it requires, all other circumstances remaining the same. Lightness and strength combined are consequently great advantages, and if a very light plough does its work as well as a heavier, there can be no doubt that it is preferable. Durability is nothing compared with the saving of one horse in three: it is cheaper to have a new plough every year than to keep an additional horse all the year. If a wooden plough is found to be more easily moved than an iron one, there can be no doubt which should be preferred.

The Flemish plough is made of wood, and is very light; the share and coulter only are of iron, besides a thin sheet of iron over the mould-board, which is shaped as if it had been rolled obliquely over a cylinder, a shape well adapted to sandy soils. In ploughing land which is more or less mellow and crumbling, the great object is to bring to the surface that portion which has lain buried, and has not served to nourish the preceding crop, and to bury that which has produced vegetation, and in which the roots of various weeds have established themselves. When manure is to be covered with a certain depth of earth, a more complete subversion is required, in order that no part of it may remain uncovered. When the land is in a compact state, from the roots which pervade it, and it is only ploughed once to prepare it for receiving the seed, much greater nicety is required to lay the slices at a certain angle so as to leave regular lines or depressions in which the seed may fall and be readily covered by the harrows which follow. In this case the angle of 45° is found to be the most convenient at which the furrow-slices may be laid against one another. The field will then have the appearance of being laid in small ridges as in the annexed figure, all towards the same side if ploughed with a turn-wrest plough, or towards a middle line if a plough with a fixed turn-furrow has been used. To produce this regularity, the end of the turn-furrow is made to press on the slice turned over. And if the mould-board be convex, as it is in most Scotch ploughs, and in those made by Hornsby of Grantham, this pressure is applied just at the right place to close the junction of the several slices.

Fig. 10.



When the seed is to be dibbled on the sward, which is reversed by a single ploughing, it is necessary that the sod should be completely turned over and laid flat. To do this, and at the same time to bury all the grass, requires the furrows to be very equal and parallel; so that when a roller has gone over the land, it is perfectly flat, without any interstices between the slices which are turned over. It requires a good ploughman to do this perfectly.

When clover-lea or old grass is ploughed up, it is difficult to bury all the grass which grows on the edge of the slice; and if it remains exposed, it will grow and increase to the detriment of the corn. To prevent this, a wing is sometimes added to the side of the coulter, a few inches from the point, or an additional skim-coulter is made to precede the ordinary coulter of the plough. It cuts a small horizontal slice off the surface before the sod is turned over, and this falls into the bottom of the furrow and is buried there. The coulter with such a wing is called a skim-coulter, because it, as it were, skims the surface. This instrument may require an additional horse to be put to the plough in tenacious soils, but this cannot be avoided. There is no doubt that no more horses should be put to a plough than can do the work; but whatever be the number required, the work must be done well. There is no saving in doing the work imperfectly. The discussions about the number of horses which should draw a plough might easily be settled, if the nature of the soil were sufficiently taken into consideration. The shape of the plough may make some difference, but the tenacity of the soil makes a much greater.

Very little attention was formerly paid to the straightness of the furrows. It was natural to follow the shape of the boundary of the field, which was seldom straight; and this practice increased gradually till no straight furrow was to be seen; and there was a prejudice, if not a superstition, in favour of crooked ridges. Those who defended them with the least vehemence, asserted that if crooked furrows were not better than the straight, the difference was unimportant; but no curves can be laid so perfectly parallel as two straight lines. Every deviation from parallelism causes a defect in the contact of the slices, and a loss of force by the obliquity of the draught. A superficial observer would not perceive this, but minute examination proves it. Hence equal and straight furrows are a sign of good ploughing.

When the land lies on a dry subsoil, and no more moisture remains in it, after continued rains, than is useful to promote vegetation, it may be ploughed quite flat. This may be done by a plough with a moveable turn furrow, or by ploughing in very great widths. The best way is to draw a furrow the whole length of the field in the middle, and plough towards this from both sides. If the field is wide, it is most convenient to plough it into several broad stitches, each a certain number of perches in breadth. A perch (16½ feet) is a very common width for a "stitch," and convenient to guide the sower or the drilling-machine.

On wet undrained soils it is necessary to lay the land in a rounded form, in order to let the superfluous water run off into furrows, from which it is conducted by proper channels into the ditches. In this case half a perch is a common width for each stitch, or land, as it is sometimes called. It requires some practice to lay up a land in a rounded form from a flat surface. After cross-ploughing and harrowing, the first furrow is drawn wide and shallow, and the earth is thrown upon the surface to the right: when the plough returns, it takes another furrow about nine or ten inches from the first, laying the earth or furrow-slice somewhat obliquely over the first. At the next turn another slice is laid, meeting the last at an angle, the first slice being quite covered by the two last. This now forms the crown of the ridge; and the succeeding slices are laid obliquely, leaning to the right and left till the required width is obtained. Another land is now begun at the distance of a quarter of a perch from the last furrow, and laid exactly in the same manner. When the two lands meet, the intervening furrow, which had been purposely left shallower, is deepened; and there is a furrow between every two lands, the bottom of which is considerably below the bottom of the other furrows. When this field is ploughed again after harvest, the work is reversed; the furrow between the lands is filled with the first slice, and another is placed over this, which now becomes the crown of the land to be formed: this is called ploughing crown and furrow. When the lands are ploughed towards the crown, it is called gathering. By gathering several times in succession, the soil is much raised at the crown at the expense of the sides. This was the old practice, when lands were laid very wide and very high; in common fields, the land or stitch was often the whole width of the possession, from which came the name of land. In Scotland they are called riggs.

Fig. 11.

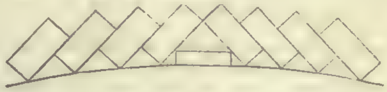


Fig. 12.

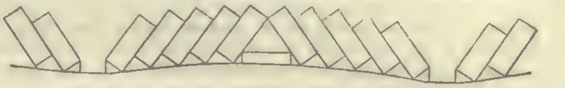


One of the most useful operations in ploughing land is to cross the former furrows, by which means the whole soil is much more completely stirred; and if any part has been left solid without being moved by the plough-share, which is called a balk, it is now necessarily moved. The leaving of balks is a great fault, and is owing to the sole of the plough being narrower than the furrow-slice, and the wing of the point too short, or to the ploughman not holding his plough upright. The share should cut the ground to the whole width of the furrow, that no roots of thistles, docks, or other large weeds may escape and grow up again. The Roman authors recommended the use of a sharp rod or stake inserted horizontally into the ground, to discover if there were any balks, which, with their ploughs, must have been often left, if the ploughman was not very careful to make close and small furrows. Many ploughmen hold the plough in an oblique position; the bottom of the furrow is consequently not level, and the soil is not stirred equally. This is a great fault, especially in wet ground; for the furrows thus become channels in which the water remains, not being able to run over the inequalities of the bottom. It is of no use to lay the surface convex, if the solid earth below lies in hollows or gutters. The water naturally sinks down into the newly-ploughed land, and if it be undrained it sinks only till it meets the solid bottom which the plough has gone over; if it can run over this into the deeper furrows between the stitches, it evaporates or runs off, and the land is left dry, and so consolidated as to let the water run along the surface without sinking to any depth; but if the bottom is uneven, it remains in the hollows, and stagnates there, to the great injury of the growing crops.

There are various modes of ploughing land when it is intended to pulverise and expose it to the sun in summer, or the frost in winter, to purify and fertilise it. To expose as great a surface as possible, the whole field is laid in high and narrow ridges, bringing to the surface all the fertile portion of the soil, and often also a portion of the subsoil so as to deepen the productive portion and give more room for the roots to spread in. The simplest method of increasing the surface exposed, when the land is first broken up from pasture, or after having been some years in grass, and is in a foul state, is called ribbing, or "raftering." The plough turns up a slice, which it lays over flat on the adjoining surface. It does not cover this with the next slice, as if it were beginning the crown of a stitch, but it takes another slice at some distance, and then one parallel to the first, likewise laid flat on the solid part. When the whole field has been so ploughed, the surface consists altogether of ridges and furrows; but only half the surface has been ploughed. No grass appears, if it has been well done, the unploughed strips being covered by the slices raised by the side of them, the two surfaces with grass on them cover each other. It is left in this state till the grass is rotten, and when the sod is broken to pieces by heavy drag-harrows, the land can be cross-ploughed and cleaned or fallowed in dry weather.

There is another mode of ridging, when the land has had one or two ploughings, in order to expose it to the frost in winter, and to mellow it. The operation is somewhat similar to ribbing, but after the first slice is turned over, another is added, as deep as the plough can be made to go, so as not to bring up the subsoil; by this means the whole surface is laid in high ridges and deep furrows; and when this ploughing is reversed, in spring, the soil which has been exposed to the frost and wind is mixed with the rest, and tends greatly to mellow it. This is an excellent preparation for turnips, if the land has been well cleaned. The manure, being distributed in the deep furrows, is covered by the plough right and left, or at one operation by a plough with a turn-furrow on each side, which divides the ridge and lays half of it in each contiguous furrow. This plough is usually called a double mould-board plough, and is extremely useful in many operations of husbandry.

In order to save hands and expedite the tillage of the land, ploughs have been contrived which make two or more furrows at once. When they are well constructed, they are very useful in light soils. If it is not required to go deep, and two horses can draw a double plough, there is a decided saving of power; but if it requires four horses, nothing is gained. The double ploughs are therefore not much in use. But there are instruments which cultivate the earth, stirring and pulverising it much more speedily than the plough. Some of these will stir the ground to the depth of seven or eight inches, going over a width of five or six feet at once. Such an instrument is preferable to the plough, after the ground has already had a certain degree of stirring, and is become mellow and crumbling; but to break up pasture or clover-lea, there is nothing so efficacious as the plough, which cuts regular slices and lays them over, so that all the grass shall rot, and the roots, being exposed to the air, shall decay, and thus furnish food for other crops.

The instruments which have been invented to save the time and labour required by repeated ploughings are very numerous. Some of the most useful have been noticed before. [ARABLE LAND.] New ones are daily invented, and some are supported by wheels, which render them both lighter and more convenient. They are easily raised out of the ground, when not intended to work, and the depth to which they are let down is more easily regulated.

Deep ploughing is generally acknowledged to accord with the best husbandry, where the subsoil is dry naturally, or has been artificially drained; but some inconvenience may arise from bringing a barren subsoil to the surface, in trench-ploughing by two ploughs following each other in the same furrow. It has therefore been suggested to take off the turn-furrow from the plough which follows the first, so as to stir the subsoil without bringing it to the surface. [ARABLE LAND.] This idea has been improved upon by constructing a subsoil-plough of great strength, which will go very deep into the ground and stir the subsoil a foot or more below the bottom of the usual furrow. Mr. Smith of Deanstone has invented one made entirely of iron, and Sir E. Stracey has constructed another with a small wheel in front very strongly put together, although the beam is of wood. Mr. Read, of Regent Street, London, has since manufactured another wholly of iron; and, in its turn, this has been greatly improved by the Marquess of Tweeddale, and is made by Mr. Slight of Edinburgh. This plough requires four horses in the most favourable soils, and six in tenacious clays, to keep up with the common plough, which always should precede it. Sometimes however the subsoil-plough may be used alone, where the surface is already mellow and crumbling.

Many different ploughs have been invented for the purpose of saving labour in draining land. As they all cut out a slice from the bottom of a furrow and raise it up to the surface of the ground, they are of little use in crumbling soils, and in the most tenacious require the assistance of much manual labour to complete the work. They act on the principle of the carpenter's tool by which a groove is formed in the edge of planks or deals, when they are intended to be joined closely as in a floor. This instrument is also called a plough; but the uniform tenacity of the wood allows a narrow chisel to cut an even regular groove. In the draining-plough the two sides of the drain are to be cut obliquely downwards and the bottom scooped out evenly. The plough requires to be often adjusted, and the deep furrows to be kept cleared from loose earth by means of spades and scoops. In this way, drains may be made from 15 to 18 inches deep, in which loose stones or tiles may be laid to form a channel for the water. The expense is much less than when the drains are made with the spade.

When grass-land lies low and wet on a very tenacious subsoil, a plough is sometimes used which consists of a cylinder of iron pointed at one end, and connected with a strong beam by a thick plate of iron which is sharp on the side nearest the point of the cylinder, and acts as a coulter. This instrument is forcibly drawn horizontally through the stiff subsoil at a depth of 18 inches to 3 or 4 feet, so as to leave a round channel like a pipe where the cylinder has passed. This has been called a mole-plough, the passage made by it under ground resembling the workings of a mole. It is most effectively drawn by steam power, but though easy and expeditious, it is only as a means of temporarily draining land that it can be approved.

Various ploughs have been constructed with the intention of diminishing the draught, or improving the form of the turn-furrow; but it may suffice to name as the most distinguished manufacturers of the present day—Messrs. Ransome of Ipswich; Messrs. Howard of Bedford, and Messrs. Hornsby of Grantham. In the application of steam to the impulsion of the plough, the effect sought to be produced is the same, the difference is in the power, and various patents have been obtained for steam-ploughs.

PLOUGH-MONDAY, the Monday next after Twelfth Day, fixed upon by our forefathers as the period when the labours of the plough and other rustic toils begin. In Derbyshire, and in some of the northern counties, the young men formerly used to yoke themselves and draw a plough about with music on this day; one or two persons, disguised in antic dresses, like jack-puddings, accompanying them, and going from door to door, soliciting plough-money to provide drink. In some places it was a custom, if the ploughman, after that day's work, came with his whip to the kitchen hatch, and cried "Cock in the pot," before the maid could cry "Cock on the dunghill," he gained a cock for Shrove-Tuesday. Tusser, in his 'Five Hundred Points of Husbandry,' mentions Plough-Monday among the ploughman's feast-days.

(Brand's *Popular Antiq.*, edit. by Sir H. Ellis, vol. i.; Brady's *Clavis Calendaria*, vol. i.)

PLUM. The *Prunus domestica* is generally considered as the species which has given rise to the numerous varieties of this fruit; but both *Prunus insititia* and *P. spinosa* have most probably contributed. These species are indigenous to a great portion of the northern hemisphere, Britain included. Their range may be stated to extend from Norway to Barbary, and from Portugal to Cashmere, and even Nepaul. Damascus was formerly celebrated for this fruit: branches of the plum are represented on Damascus medals; and many of the varieties now in cultivation still retain the name of this place, or it is employed as a distinguishing prefix to a number of subvarieties; thus the French enumerate upwards of twenty varieties of *Damas*. In this country the name of *Damascene* was given to those varieties which may be supposed to have been brought from Damascus, or to others similar; but the corruption of this to *Damson* has been long established. Whatever region may be the origin of them, it is certainly to France that we are indebted more immediately for the greater part of the varieties now actually cultivated.

In the 'Catalogue of Fruits,' published by the Horticultural Society, 274 varieties are named; but the mussel, orleans, and damsons are those best fitted for orchard culture in England, among the purple fruits; and the green-gage, especially in the southern parts, and the bullace, a coarse but useful variety, everywhere, among the pale fruits.

The cultivation of the plum is not difficult. The tree is hardier than the cherry-tree; but the blossoms are equally tender. The trees succeed in any free soil, not too dry, but by no means stiff or clayey. Their roots extend horizontally, and are apt to throw up suckers, which must be destroyed on their first appearance, otherwise they rob the tree, and form protuberances on the roots. Too much manure will actually kill the trees; and at all times a medium state of vigour should be aimed at. Excessive luxuriance is the forerunner of gummy exudations; and, on the other hand, if the tree be stunted and the vessels contracted by drought or other causes, whereby the sap is obstructed, gum is in that case also induced. Pruning should be applied to the plum in the same manner as to the peach; and in the management of standards care should be taken to destroy useless limbs on their first appearance, instead of waiting till the shoots to be removed become large branches. In training the plum the new wood should be cut away in winter, except those at the end of branches, and these should be cut back to half their length. The varieties are propagated both by budding and grafting; and for the latter, as the buds push early, the cuttings should be taken off not later than February. The wood-buds are easily distinguishable from the flower-buds by being more pointed.

PLUMBAGO. [GRAPHITE.]

PLUMBATES. [LEAD.]

PLUMBETHYL. [ORGANO-METALLIC BODIES.]

PLUMBITES. [LEAD.]

PLUMBLINE. When a heavy body suspended by a flexible string is at rest, the line passing through the point of suspension and the centre of gravity of the weight is in the direction in which gravity acts. The *horizon* is a plane perpendicular to this line, and the *zenith* is that point of the heavens marked out by the continuation of the line upwards. If the string be *perfectly* flexible, it will coincide with the theoretical line above described.

The application of the plumbline to the arts does not require any explanation here. Nor is it necessary to describe it in connection with astronomical instruments, as in most cases it has been superseded by the spirit level, or observation by reflexion.

PLUTO (Πλούτων), more frequently called by the Greeks Hades (Ἅιδης), and by the Romans *Orcus* and *Dis*, was the son of Kronos and Rhea, and the brother of Zeus and Poseidon. He was the deity that presided over the region where the departed souls of men were placed: the Zeus of the infernal regions. Hades, which is also written without an aspirate (Ades), is a word of uncertain etymology. Pluto is supposed to be connected with the Greek word signifying wealth (πλοῦτος), since the precious metals are found beneath the earth's surface, below which the abode of Hades was generally placed, and he alone was the possessor and the giver of them. The Latin Dis has the same meaning. Orcus is probably connected with the words *εἴργω* and *arceo*, and may signify "bound or restrained."

Pluto is represented by the ancient writers as a gloomy deity, inexorable to the prayers of mortals, and hated by the human race above all the gods. ('Il.,' ix. 159.) Whilst in his own kingdom he was unaware of what passed on earth, or in Olympus; but he sometimes ascended to Olympus. His wife was Persephone, called by the Romans Proserpina, whom he carried off whilst she was gathering flowers. [PERSEPHONE.]

In the 'Iliad' (ix. 569; xx. 61; xxiii. 100), and in the 'Theogony' of Hesiod (455, 767), the abode of Hades is said, as has been already stated, to be beneath the earth; but in the 'Odyssey' it is placed in the regions of darkness beyond the stream of ocean. ('Od.,' x. 508; xii. 81.)

The temples and statues of Pluto appear to have been very few. Pausanias relates (i. 28, § 6), that there was a statue of Pluto in the temple of the Eumenides, on the Areiopagus of Athens; and the same writer also informs us (v. 20, § 1), that there was a statue of this god in the temple at Olympia. There were also temples sacred to Pluto in Elis, Pylos, and other parts of Greece. Black sheep, a male and a female, were the sacrifices offered to Pluto and Persephone; and the person offering them was obliged to avert his face.

Few representations of Pluto by Greek artists have come down to us. In the statues and busts which are known, he resembles his brothers Zeus and Poseidon; but the countenance has a gloomier cast, the hair is lower on the forehead, and the drapery heavier. On vases, urns, and sarcophagi, he is more frequently represented carrying off Persephone, or enthroned with Persephone seated beside him.

In later writers, the word Hades also signifies the abode of the dead, as well as the deity who presided over it.

PLUTUS (Πλοῦτος), the personification and the giver of wealth, is said by Hesiod ('Theog.,' 969) to have been the son of Demeter and the hero Iasius. He is said to have been blinded by Zeus, in order that he might distribute his favours indifferently to the evil as well as to the good. (Aristoph., 'Plutus,' 90.) Plutus appears as an actor in the comedy of Aristophanes named after him; but we have no particulars respecting his worship. In the temple of Fortune at Thebes, Plutus was represented as a child in the arms of Fortune (Paus., ix. 16, § 1), and at Thespeia in Bœotia there was a statue of Plutus placed by the side of one of Athena Ergane. (Paus., ix. 26, § 5.) Pausanias also mentions a statue of Plutus in the arms of Peace, which Cephisodotus made for the Athenians. The attribute of Plutus was a cornucopeia.

PLUVIOMETER. [RAIN-GAUGE.]

PNEUMA'TICI (οἱ πνευματικοί), a medical sect founded by Athenæus about the middle or end of the 1st century A.D. [ATHENÆUS in BIOG. DIV.] Their principal doctrines have been noticed in the life of their founder. The sect appears to have existed but a short time, namely, from the reign of Vespasian to Antoninus Pius, and never to have enjoyed any great celebrity. For further information concerning it the reader may consult Wigan, 'Præfat. in Aret.;' Ackermann, 'De Aretæo;' and especially Osterhausen, 'Dissert. Inaugur. de Sectæ Pneumaticorum Medicorum Historia.'

PNEUMATICS. This name is given to that part of physics in which are contemplated the mechanical properties of elastic fluids, principally atmospheric air. The word is derived from πνεῦμα, 'breath or spirit,' and pneumatology is a term which was once applied to the division of science now called metaphysics.

The mechanical properties of air appear to have been, to a certain extent, known to the ancients. Aristotle must have been aware of its materiality, and of its tendency to descend towards the earth, like other heavy bodies, for he observes that if a bladder be filled with air, it weighs more than when empty: the observation proves at least that he had the idea, but it may be doubted whether or not he ever made the experiment, since it is not probable that he had the means of weighing the full bladder in vacuo, or that he could keep it distended when the air was extracted from it. The invention of a species of forcing-pump for raising water, and of instruments for producing sounds by the passage of air through orifices in tubes, both of which are ascribed by Vitruvius (lib. ix., x.) to Ctesibius, who lived about 130 years B.C., are proofs that the elastic force of compressed air must have been then apprehended and made subservient to purposes connected with practical utility.

The ascent of water in pumps, on raising the piston, must have been for ages observed, without a suspicion being entertained of the cause; and the principle that the existence of a vacuum was impossible, was held to afford a sufficient explanation of the phenomenon. Even Galileo, when made aware, by the formation of a vacuum between the piston and the water when the latter was at its greatest height in a pump, that the principle was unfounded, had recourse to another which was equally remote from the truth; for he is said to have ascribed the ascent of the water to the attraction of the piston, and to have accounted for the height of the column never exceeding a certain quantity (about 34 feet) by a supposed equilibrium between the weight of the column and the attractive power of the piston. The steps by which Torricelli arrived at the discovery of the true cause of the phenomenon, and at the same time, the determination of the pressure of the atmosphere by the weight of the column of mercury supported in a tube closed at the upper extremity, are noticed under BAROMETER.

Soon after the commencement of the seventeenth century, the idea of ascertaining with precision the state of bodies with respect to temperature by the expansion of fluids when acted on by heat, is said to have occurred to the members of the Academy del Cimento, at Florence; and this gave rise to the invention of an instrument of great importance, as well for many occasions of ordinary life, as for the purposes of pneumatical science. [THERMOMETER.]

The desire of perfecting the theory for determining the heights of mountains by the barometer, led to numerous researches in order to ascertain the relations between the condensation of air and the forces compressing it, and also to discover the effects produced by variations of temperature. About the year 1650, Boyle in England, and about 1676, Mariotte in France determined from experiments, that when the temperature was constant, the density of air was proportional to the compressing force; but it was not till a century afterwards that De Luc determined the expansion consequent upon given increments of temperature.

In the beginning of the eighteenth century, steam began to be employed as a moving power for pumps and other machinery. The law of the resistance of the air to bodies moving in it was discovered by Sir Isaac Newton; but the intensity of this resistance against military projectiles was first determined, for the inferior velocities, by Robins, in 1740; and Dr. Hutton subsequently obtained a formula which, with perhaps sufficient correctness, may be employed with any velocity whatever. [GUNNERY.] The expansion of fired gunpowder has been determined from the researches of Robins, Euler, and Hutton; and that of steam has been investigated by Dalton in England, and by Prony, Arago, and other distinguished physicists in France. [STEAM.]

If a fluid be conceived to be perfectly elastic, it is evident that it can be made to occupy a given volume only by being confined within a close vessel, or by the pressure of a circumambient fluid. In the latter case it is easy to perceive that while the temperature of the elastic fluid remains the same, the spaces occupied by it will be diminished when the compressing force is increased, and increased when the latter is diminished; and that the density, or degree of closeness of the particles, will vary directly with the change of volume. Now the compressing forces which are made to act on the surface of an elastic fluid are usually estimated in terms of the pressure exerted by a vertical column of the atmosphere, its base being equal to some unit of superficies, as one square inch or foot. Whatever be the constitution of such column, its weight or pressure is known, in a given state of the atmosphere, by direct experiment, and this is usually designated the pressure of one atmosphere: the same pressure is also frequently expressed by the height of the column of mercury which is supported in a barometer-tube by the counteracting weight of the atmospheric column.

A simple experiment suffices to show the relation between the density and elasticity of a fluid and the compressing force. Let mercury be poured into a bent tube open at one end and closed at the other; the sum of the weights of the column of mercury and of the atmosphere above it in the open tube, will reduce the air in the closed tube to a volume less than that which it previously occupied. Let, then, more mercury be added, and the volume of air will be still further reduced at every addition of mercury: and it will be found that the volumes of air vary inversely as the sums of the weights of the mercury and atmosphere. Therefore, since the density of an elastic fluid is inversely proportional to the space it occupies, it follows that the densities are directly proportional to the compressing weights; and since the weights of the mercury and atmosphere together, in the open tube, are balanced by the elastic force of the condensed air in the close tube, that elastic force is also directly proportional to the compressing force, that is, to the density. [AIR.] This is the law of Boyle and Mariotte, and though it cannot be said to be absolutely correct for very great pressures, it is sufficiently so for all practical purposes. (See the elaborate experiments of Magnus, 'Annales de Chimie et de Physique,' 3 serie, iv.; and of Regnault, iv. and v.)

The following table, extracted from the results of the experiments made by MM. Prony, Arago, and others, exhibits the volumes and elasticities of a given quantity of atmospheric air under different pressures, the temperature being nearly constant, and expressed by 14° of the centigrade thermometer (57·2° Fahr.), and, as far as it extends, it confirms the law above mentioned. The first of the columns expresses the pressure or elasticity in multiples of the weight of an atmospherical column; the second expresses the same by the height, in inches, of the column of mercury supported in a barometer tube; and the third column contains the corresponding volumes.

Atmospheres.	Inches, Eng.	Volumes.
1	30	1·0000
5	150	·1989
11·3	339	·0884
16·5	495	·0601
21·7	651	·0457
24	720	·0411
27	810	·0369

The law being admitted, it may be proved that the particles of an elastic fluid repel each other with a force which varies inversely as the distance between them. For let the volume of fluid be in the form of a cube, and let the compressing force act perpendicularly on one of its faces; then, if d represent the distance between any two adjacent particles of fluid, the number of particles in the surface pressed will vary as $\frac{1}{d^2}$. Now assume that the repulsive force (perpendicularly to that surface) between any two adjacent particles in the volume varies as d^n; then the whole repulsive force on that surface, and, consequently, the compressing force, will vary as d^{n-2}. If D represent the density of the fluid, d will vary as $\frac{1}{D^{\frac{1}{3}}}$, or $D^{-\frac{1}{3}}$; therefore, substituting $D^{-\frac{1}{3}}$ for d in the last expression, the whole repulsive force varies as $D^{-\frac{1}{3}(n-2)}$. But, agreeably to the law above mentioned, the compressing force varies as D; therefore the exponent $-\frac{1}{3}(n-2)$ must be equal to unity, and hence $n=-1$. It follows therefore that the repulsive force between any two adjacent particles varies as d^{-1}, or inversely as the distances of those particles from each other. Sir I. Newton however observes (lib. ii., prop. 23, schol.) that this law holds good only when the repulsive power of any particle does not extend much beyond those which are nearest to it.

If P and P′ represent the pressures exercised upon a square unit of the superfices bounding an elastic fluid, and the volumes of the fluid under those pressures V and V′; also if the densities be D and D′ respectively, we shall have

$$P : P' :: V' : V, \text{ or } P.V = P'.V',$$
$$\text{and } P : P' :: D : D', \text{ or } P.D' = P'.D;$$

whence, by equality of ratios,

$$V : V' :: D' : D, \text{ or } D.V = D'.V'.$$

Considerable difficulty is found in determining the specific gravities of gases with precision, and different experimenters have obtained results which do not exactly agree. The value generally adopted when the height of the column of mercury in the barometer is 30 inches, and the temperature is 60° Fahr., is 31·074 grains as the weight of 100 cubic inches of dry air. Other physicists have found it as low as 31·0117 and 30·935 grains; but the former is probably most correct, as it agrees with the density of air as deduced from that of a mixture of oxygen and nitrogen in the proper proportions to form air. Air is therefore $\frac{1}{815}$ of the density of water. The experiments of Dalton have led to the conclusion that the weight of a cubic foot of steam when at the temperature of 212° Fahr., the height of the barometrical column being 30 inches, is 253 grains troy; by others it has been found to be 254·7 grains; and it appears that within considerable limits the expansion of the volume of any gas is proportional to the increments of temperature, measured by the degrees of the thermometer. The absolute value of the expansion is not precisely known; that of air is stated to be equal to about $\frac{1}{481}$, and that of steam about $\frac{1}{[illegible]}$ of the volume, for one degree of Fahrenheit's thermometer. [AIR.]

The following table, from the observations of MM. Dulong and Petit, exhibits the volumes assumed by a given quantity of air at different temperatures between the boiling-point and near the freezing-point of mercury:—

Temperatures.	Volumes.
—33°	0·8650
32	1·0000
212	1·3750
302	1·5576
392	1·7389
482	1·9189
572	2·0976
680	2·3125

It has been mentioned that the rate of expansion of all gases is equal and uniform at all degrees of temperature and pressure, and that the amount of the expansion is $\frac{1}{491}$ of the bulk occupied at 32° Fahr., for every degree of temperature, so that a quantity of any gas, which, at 32° Fahr., measured 491 parts, will, at 33° Fahr., measure 492 parts, and so on. If, then, it were required to find the volume which 9·2 cubic inches of any gas, measured at 70° Fahr., would have, when reduced to 60°: since 70 − 32 = 38, 491 parts of the gas at 32°, would become 529 parts at 70°. Again, 60 − 32 = 28, so that the gas at 60° would, similarly, occupy 519 parts. Hence, we have the proportion, 529 : 519 :: 9·2 : x (= 9·026 cubic inches).

From experiments it has been concluded that, while steam is in contact with the water from which it is formed, its expansive force increases in a geometrical progression, so long as its temperature is at the same time increased in an arithmetical progression, but the relation between the elastic force of this gas and its temperature, in that state, is as yet far from being certainly known. Under the word ELASTICITY is given a table of the elastic forces of steam at temperatures between the freezing and boiling states of water; and the following table, extracted from those which have been formed from the results of the experiments of Mr. Dalton, Dr. Ure, and the French physicists, may also be useful as a means of affording a near estimate of the force at high temperatures. The first column contains the temperature of the water and steam in degrees of Fahrenheit's thermometer; the second is the measure of the expansive force by the number of inches in the height of the column of mercury which on a given superficies would counterbalance it; and the third, the like measure expressed by multiples of the weight of the atmospheric column when the air is in its ordinary state:—

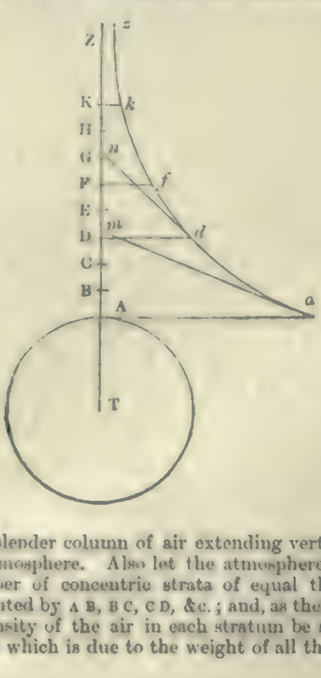
Temperature.	Inches, English.	Atmospheres.
212°	30	1
220	35·54	1·18
240	51·7	1·72
260	72·3	2·41
280	101·9	3.06
300	139·7	4·66
312	165·5	5·52
340	231·	7·7
357	296·79	9·893
389	435·9	14·53
408	541·5	18·05
419	613·2	20·44
435	719·8	23·994

When steam is not in contact with the water from whence it is formed, and when it is subject to a constant pressure under which it may expand in every direction (as when it is formed in the atmosphere), an increase of temperature will not produce an increase of density, but merely of its elastic power. Again, if steam be in contact with its water, and the temperature remain constant, its density, whether in air or *in vacuo*, will remain constant, and its volume only will vary. But if, in this case, its volume be kept constant, and the temperature be increased, its density will rapidly increase, as before, until the whole of the liquid is evaporated, and then the expansion of the steam will follow the usual laws of permanent gases. The only difference in these experiments between using a vessel containing air, and one having a vacuum inside is, that in the former case the results do not *at once* appear, until time has been allowed for diffusion.

It has been found that the volume of gas disengaged from gunpowder is equal to about 300 times the volume of the powder itself; and that its expansive force, when increased by the heat which is generated at the time of the explosion, is about 1500 times as great as the pressure of the atmosphere in its ordinary state. It must consequently exert a pressure against a cannon-ball, and the interior of the chamber of the gun, equal to about 15,000 pounds upon every square inch of the surface upon which it acts.

The fact that the density of air varies with the compressing force is sufficient to show that the atmosphere about the earth cannot be of uniform density; and it is also evident that the density must diminish from the surface of the earth upwards, according to some law depending on the height of any point above the earth, or rather upon the weight of the mass of air above that point. It might, at first, be supposed that the atmosphere would extend upwards to a height at which the centrifugal force of the particles of air (by the diurnal revolution) is equal to the force of gravitation; and it is shown by Poisson ('Traité de Mécanique,' tom. ii., 619) that, conformably to this principle, the height of the atmosphere at the equator should be equal to about five times the semi-diameter of the earth. But it is probable that, long before this height is attained, the air loses its elasticity by the cold in the upper regions, or that its expansion is destroyed by the pressure of the ethereal fluid which is diffused through infinite space. By the duration of twilight it is inferred that the atmosphere is capable of reflecting the sun's rays at the height of about 45 miles above the earth, and it is probable that some light is reflected from a still more elevated region.

In order to determine the law by which the density of the atmosphere diminishes at increasing distances from the earth's surface, on the supposition that the action of gravity and the temperature of the air are constant, let T be the centre of the earth, and let A Z be the height of a very slender column of air extending vertically upwards to the top of the atmosphere. Also let the atmosphere be divided into an infinite number of concentric strata of equal thicknesses, which latter are represented by A B, B C, C D, &c.; and, as these thicknesses are small, let the density of the air in each stratum be supposed uniform and equal to that which is due to the weight of all the strata above it.



Let d_1, d_2, d_3, &c., represent the densities of the several strata whose heights are A B, B C, C D, &c.; these terms may also represent the weights of the slender columns A B, B C, C D, &c.; consequently the weights of the columns A B, A C, A D, &c., may be respectively represented by d_1, $d_1 + d_2$, $d_1 + d_2 + d_3$, &c. Then, the density in each stratum being proportional to the weight, or sum of the densities, of all above it, we have

$$d_1 : d_2 + d_3 + d_4 + d_5 + \&c. :: d_2 : d_3 + d_4 + d_5 + \&c. \quad (I)$$

In like manner

$$d_2 : d_3 + d_4 + d_5 + d_6 + \&c. :: d_3 : d_4 + d_5 + d_6 + \&c. \quad (II)$$

or, by composition,

$$d_1 : d_1 + d_2 + d_3 + d_4 + \&c. :: d_2 : d_2 + d_3 + d_4 + d_5 + \&c. \quad (III)$$

In like manner

$$d_2 : d_2 + d_3 + d_4 + \&c. :: d_3 : d_3 + d_4 + d_5 + \&c. \quad (IV.)$$

Then, from (I) and (III), by equality of ratios, we have

$$d_1 : d_2 :: d_2 : d_3.$$

And, from (II) and (IV), by equality of ratios, we have

$$d_2 : d_3 :: d_3 : d_4;$$

and so on.

Thus d_1, d_2, d_3, d_4, &c., are in a geometrical progression decreasing.

Now A B, A C, A D, &c., form an arithmetical progression increasing; or, reckoning both the heights and the densities from any point, as K, downwards, the former (that is, K H, K G, K F, &c.) form an arithmetical progression, and the densities in K H, H G, G F, &c., form a geometrical progression; both increasing. But a series of numbers in an arithmetical progression being made to correspond to a series in geometrical progression, the former numbers are logarithms of the latter; and thus the distances K H, K G, K F, &c., may be considered as representing the logarithms of the densities in the strata K H, H G, G F, &c., respectively.

Imagine any point K to be the origin of the abscissæ (represented by x) on the vertical line Z A; and imagine any horizontal ordinates K k, F f, &c. (represented by y) to be drawn; then, if K F, K D, &c., be proportional to the logarithms of F f, D d, &c., the line $a\,d\,f\,k$, &c., is called the logarithmic curve, and its equation is log. $y = x$ log. a, or $y = a^x$ [LOGARITHMIC CURVE], where a is some constant which is called the base of the system of logarithms appertaining to the particular curve.

Now it has been demonstrated by mathematicians, that if tangents $a\,m$, $d\,n$, &c., be drawn from any points in the curve, the subtangents A m, $m\,n$, &c., will be equal to one another; and that the area comprehended between the infinite branch $a\,z$ of the curve, its asymptote A Z, and any ordinate A a, D d, &c., is equal to the product of the constant subtangent, or modulus of the curve, and that ordinate: hence the area between A a and the infinitely remote summit Z is equal to A a × A m. Also, by the nature of logarithms, the logarithms of the same natural number in different systems of logarithms bear to one another the same proportion as the moduli of those systems. We have therefore only to find the value of the subtangent A m, or modulus, for what may be called the atmospherical logarithms. For this purpose, let h denote the height of a homogeneous atmosphere whose density is equal to that of the real atmosphere at the surface of the earth, which density is represented by the line A a in the above diagram; then h × A a will represent the weight of such homogeneous atmosphere, or its pressure on the point A. But the area between Z A, A a, and the curve being supposed to be made up of the infinite number of ordinates A a, D d, F f, &c., which, severally, represent the densities of the air at the points A, D, F, &c., in the infinitely high column A Z of atmospherical air; that area, namely, A a × A m, may represent the weight of such column, or the pressure of the real atmosphere on the point A; this being made equal to the former pressure, it is evident that we shall have A $m = h$. Thus the height of a homogeneous atmosphere exercising at A the same pressure as the real atmosphere, will be the subtangent, or modulus, of the atmospheric logarithms. The value of h is determined by a proportion in which the heights of the column of homogeneous air, and the column of mercury which holds it in equilibrio, are to one another inversely as the specific gravities of the two fluids. [HYDROSTATICS.] Now the specific gravities of air and mercury being, respectively, proportional to about 1·22 and 13568; and the height of the column of mercury in the barometer being 30 inches when the temperature is expressed by 55° Fahr., we get 27803 feet, for the value of h. Hence the height of a homogeneous atmosphere would be about 27803 feet, or a little more than 5 miles from the sea level, while the mean density of the atmosphere (in its present state) is at about 3¼ miles.

The mountain-barometer, as it is called, is usually provided with an adjusting screw, by which the surface of the mercury in the cistern may be made to coincide with the zero of the scale of inches by which the height of the column is expressed; but those of a more portable kind have not that adjusting screw, and then a correction must be made for the error of the scale. [BAROMETER.]

Water boils when the elastic power of the vapour formed from it is equal to the incumbent pressure; and consequently the temperature at which the boiling takes place in the open air will depend upon the weight of the atmospheric column above it. Therefore, since this weight becomes less as the station is more elevated, it is evident that water will boil at a lower temperature on a mountain than on the plain at its foot; and the Rev. Mr. Wollaston constructed an instrument called a thermometrical barometer, by which, on the principle just mentioned, the relative heights of stations can be found. A tube containing the mercury is provided with a graduated scale, and, when used, the bulb is placed in a vessel of water, which is made to boil by means of a spirit-lamp. An improved form of the apparatus is represented under BOILING OF LIQUIDS.

In order to determine the heights of stations merely by the knowledge of the temperature at which water boils, the formula $F = \left(\frac{t + 75^\circ}{85}\right)^6$ given by Mr. Tredgold, might be employed. Here t is the temperature of the boiling water at the station, expressed in degrees of the centigrade thermometer; F is the measure of the elastic force of the steam at the temperature t under the pressure of the atmosphere, and is expressed by the corresponding height, in centimetres, of the column of mercury in a barometer.

The velocity with which air flows into a vacuum through an aperture in a vessel follows the same law as water or any other non-elastic fluid [HYDRODYNAMICS]; for though, in the former case, the quantity of air passing through the orifice in a given time varies with the density of that which successively comes to the orifice, yet the pressure by which the air is forced out varying in the same proportion, the velocity, by dynamics, remains constant.

Now, the velocity acquired by a falling body in vacuo is known to be $= \sqrt{2gx}$, if $g = 32$ feet, and $x =$ height fallen through. (DYNAMICS.) Hence, if $v =$ velocity with which the air rushes through a small hole into a vacuum at the sea-level, $v = \sqrt{2gx}$, namely, $v =$ the velocity of a particle of air supposed to have fallen from the height of a homogeneous atmosphere into the aforesaid hole. So that $v = \sqrt{2 \times 32 \times 27803}$, from above.

$$\therefore\ v = \text{about } 1339 \text{ feet per second.}$$

The law is the same, whether we consider the air to act only by its weight, or whether it be confined in a vessel and the efflux be produced by the elasticity. For, the air in the vessel being in the ordinary state of the atmosphere, the pressure against every point on the interior surface is equal to the pressure of the atmosphere by which, if not otherwise confined, it would be kept in its actual state; consequently it begins to flow from the orifice with the same velocity as if it had been impelled by the weight of the whole column of atmosphere above the orifice, that is, with the velocity due to the descent of a body from a height equal to that of a homogeneous atmosphere. After this moment, the density of the air in the vessel diminishing, its elasticity diminishes with it, and consequently the power of motion is diminished in the same ratio as the density. It may be added also that, since density of air increases with the pressure, an additional pressure on the fluid in a vessel will not increase the velocity of the efflux. But the law just mentioned only holds good when the vacuum is supposed to remain perfect on the exterior of the orifice: for, if the air be received in a vessel, it will expand in that vessel and re-act against the effluent air at the orifice, thus diminishing the velocity till the latter finally becomes equal to zero; and this will take place when the air has attained the same density in the two vessels.

If the effluent air be of a given density, but not the same as in the ordinary state of the atmosphere, the force by which it would be made to flow into a vacuum must be determined by the above equation $PD' = P'D$; where P is the pressure (or weight of the column) of the ordinary atmosphere, and D its density at the earth's surface; D' is the given density and P' is the required pressure or force by which that air would be impelled through the orifice. Now if air in the ordinary state be allowed to rush into a vessel containing air less dense than itself, and the velocity of efflux be required, the moving force will be the difference between that with which the ordinary air is driven through the orifice and that with which the rarer air would be so driven; that is, it may be represented by $P - P'$; then the velocities of efflux being as the square roots of the forces [HYDRODYNAMICS], if the velocity due to the force P is given, the required velocity at the commencement of the efflux may be found.

The determination of the velocity with which dry steam or any other elastic fluid rushes into a vacuum, or into a fluid of less density than itself, is made in the same manner as for air. Thus, knowing the temperature of steam, and consequently its elasticity, or the equivalent pressure, we can find the height of a homogeneous atmosphere which would produce the same pressure; and then the velocity with which the steam flows into a vacuum would be equal to that acquired by a body in falling down the height of such atmosphere. But if the steam is to flow into any elastic fluid of less density than itself, the height of the homogeneous atmosphere must correspond to the difference of the pressures arising from the different elasticities of the two fluids.

Finally, it has been lately found by some very accurate experiments recorded by Professor Potter, that, if we represent by v the theoretic velocity of efflux of air through a small orifice, and by v' the experimental velocity, then

$$v' = .65\ v, \text{ for orifices in a thin wall,}$$
$$= .93\ v, \text{ for cylindrical spouts,}$$
$$= .94\ v, \text{ for conical spouts, and those}$$

narrowing from the wall of the gasometer; so that there is, as for liquids, a true *vena contracta*, which reconciles theory with experiment, as in the case of Torricelli's theorem. [Effusion; Hydrodynamics.]

PNEUMIC ACID. The lungs of most animals contain a peculiar acid, partly free, but chiefly in the form of a soda salt, to which this name has been given. Its composition is unknown and hence its existence as a distinct acid must be regarded as doubtful.

PNEUMONIA. [Lungs, Diseases of.]

POACHING. [Game Laws.]

POETRY, in the usual and proper signification of the word, is applied to any composition in metre. It designates the outward form, not the style or the subject-matter treated. As, however, there are certain subjects, certain feelings and language, which belong to good poetry, a prose composition, in which these characteristics are visible, is often termed "poetical" or "poetry," just as a bad poem is called "prosaic." In both instances we speak thus when we wish to express praise or blame, as the case may be, and we use the words metaphorically. (See Whately's 'Rhetoric,' page 278.)

The art of poetry is an imitative art. Its object, in common with all such arts, is to give pleasure by imitation. So far music, painting, sculpture, and poetry agree. They differ in the means which each employs to effect the imitation. Music works by harmony and melody, painting by colour, sculpture by form, and poetry by words arranged in metre. In no case, however, is it the proper province of art to produce illusion, that is to say, the person whose feelings are to be affected always remains conscious that his emotion is not the result of anything really passing, but is merely analogous to that emotion which the reality would produce.

The imitative power of art thus consists in producing results resembling, but not identical with, those created by natural objects, or by human passion, character, and action. Hence the difference between a diorama and a picture, or between a waxwork figure and a statue; illusion is the aim of the one; imitation, properly so called, of the other. Hence, too, it is difficult to vindicate the mimicry of special sounds, such as hail or thunder, in music.

The metre in poetry answers a double purpose: in itself it affords pleasure by its rhythm, and acts as a powerful auxiliary to the sense which the mere words express; but, above all, it preserves the essence of art by operating as a constant barrier against any approach to reality. In this way the poet avows the fact that his work is a work of art, and he makes the reader or hearer aware of the relation in which he and the author stand to each other. The imitative power may work in safety when hedged off from real life by the fence of metrical form, and thus it is that Wordsworth lays down the "perception of similitude in dissimilitude" as one of the principles on which verse gives pleasure.

The next question is, in what mode does poetry imitate? Painting and sculpture copy outward forms themselves; poetry and music, being restricted to instruments of a different kind, aim at imitating the effect of those forms, that is to say, at producing the pleasurable emotion in the reader or the hearer, though in these cases they cannot imitate the means. On the other hand, the two former arts can only represent one moment of action or expression, and must tell their story by selecting that moment properly; music and poetry can supply a succession of images and sentiments all going to make up a whole. There is one advantage which poetry possesses over all its sister arts, viz., that of being able to assert: as it is the only art which employs words for its instruments, it is the only one which can enounce a proposition and command this element of the moral sublime.

Poetry, *ποίησις*, or "making," seems to be so called because good poetry creates or re-embodies the impressions which the poet has imbibed into his own mind by observation. This faculty of producing from such elements the impression of individual character, action, or scenery is the power which we generally term imagination. Without it, the attempt at imitation must necessarily fail. Wordsworth (Preface to 'Lyrical Ballads') says, "Poetry is the spontaneous overflow of powerful feelings; it takes its origin from emotion recollected in tranquillity. The emotion is contemplated until by a species of reaction the tranquillity gradually disappears, and an emotion kindred to that which was before the subject of contemplation is gradually produced, and does itself actually exist in the mind." This we take to be a description of the mode in which imagination works. The poet, by close and habitual observation, stores his mind with the circumstances which have given rise to or attended the production of emotion in himself. The result of this observation he works up so as to create in others an emotion kindred to that which he has himself experienced; kindred, but not identical, for, as Wordsworth truly remarks, the excitement must co-exist with an overbalance of pleasure. Now, many of the emotions which the poet excites are, when called forth by real events, peculiarly painful. It is his business so to combine them with pleasing associations, so to soften their disgusting features and render prominent their more attractive ones, and above all so to give unity to the whole, that, taken with the consciousness of their existing in a work of art, and not in reality, they become a source of exquisite delight. Such a work is reality, seen through the medium of the poet's mind, and clothed by him in a bodily form so as to retain its vividness, but lose its deformity.

It has been often observed that the language of savages is highly metaphorical, and what is commonly called poetical; that nations in their earlier stage show a peculiar fondness and aptitude for poetry. The truth is, that there exists in the mind of man a natural craving for individuality. We gain knowledge by generalising from individual objects, and we are always eager to re-embody our abstractions. Even in the most civilised state, there is a perpetual tendency in the mass of mankind towards "realism," while the consistent and familiar use of abstract terms and symbols implies long and severe discipline of the reasoning powers. These feelings are the groundwork of all allegory. If we reflect a moment, we know that "justice" means that disposition of mind which we see exhibited by individuals who are called "just," yet we speak of her as if she were a real existing being, and paint her with a pair of scales and a sword. Thus the appetite for the imitative arts is one deeply implanted in man; he cannot be satisfied unless character or action be embodied to the eye by colour or form, or brought vividly before the mind by the description of the poet. Abstract terms are indistinct, and require metaphors or similes to give them substance and make them palpable to the apprehension. One of the most wonderful phenomena connected with the Greeks is, that while the genius of the people constantly tended, as Bishop Thirlwall says, to embody the spiritual and personify the indefinite, they excelled no less in the dry and abstract studies of philosophy. If Homer, if Æschylus and Sophocles, have never been rivalled in poetry, it was Aristotle on the other hand who analysed with the greatest precision the process of human reasoning, and left us in his 'Ethics' and his 'Politics' treatises which are still instructive in their respective departments.

We must now proceed to say something of the diction of poetry. Words are the instruments of the poet; they are the tools with which he works. We think that Mr. Wordsworth pushes his theory of simple language a little too far. We fully sympathise with his rejection of "those phrases and figures of speech which from father to son have long been regarded as the common inheritance of poets." Such conventional forms of expression at last become adverse to the very object of all poetry; instead of conveying any definite or substantial image, they degenerate into mere formulæ of the vaguest and most unsatisfactory kind. But, just as metre at once gives pleasure by its adaptation to the subject-matter, and forms a sort of framework in which the poet exhibits his composition to the reader, so may language, by its appropriateness and by its dissimilitude to the phraseology of common life, supply another twofold source of pleasure. There are ballads, and even larger compositions, in which the simple and homely diction suits the treatment of the subject and adds force and strength to the expression. But, who will say that in such a work as the 'Agamemnon' of Æschylus, where the whole drama is knit together by one pervading feeling of mysterious dignity, the language should not bear a proportion to the other qualities of the work?

> "Let gorgeous tragedy
> In sceptered pall come sweeping by:"

stately and ornate diction is a part of her trappings.

It remains to speak briefly of the different moulds into which a subject may be cast by a poet, and according to which we call a poem epic, dramatic, lyric, &c. There is great difficulty in this part of our subject. The ancients, indeed, applied such terms as "epos," or "elegeion," to the outward form only, but, in modern language, the matter of a poem, its length, or its mode of treatment, often decides the class to which it is commonly assigned. Moreover, there are many works of a mixed character which we cannot place in any recognised division. To what genus do Dante's 'Divina Commedia,' Wordsworth's 'Excursion,' and Spenser's 'Fairy Queen' respectively belong? Certain broad distinctions may, however, be laid down, though they be incapable of definite application in every instance.

1. A poem may be in the form of a narrative of events which the poet professes to recount; although he sometimes introduces his heroes as speaking in the first person, and uses the historical present tense for the sake of greater energy, still the events are supposed to be *past*. The subject-matter is external, that is to say, the writer does not merely pour forth his own feelings as excited by certain actions or circumstances, but describes the actions or circumstances themselves. Of this kind is all epic and narrative poetry.

2. A poet may develope the action to the reader or supposed spectator by imagining that the personages of the story show its progress and their own characters by what they themselves say and do, not by what the author narrates of them. Here the time is supposed to be present, and the subject matter still more purely external. Dramatic poetry, with all its numerous subdivisions, is of this kind.

3. The author may principally aim at expressing the overflow of his own emotions and his own sentiments, instead of narrating what is past, or supposing something present to be acted before us. His object will then be to awaken an echo of similar feelings in the reader

or hearer, and thus *imitate* the action of those impulses which have previously excited such feelings in his own mind. Most short compositions intended to be sung belong to this class. If the tone of thought is enthusiastic and the metre irregular, we call the work an ode; if it express tender or mournful feelings in a more regular form, it is an elegy; the name of "sonnet" marks the outward form only. Perhaps no general word can be found so applicable to the greater part of those compositions, which are neither epic nor dramatic, as the term "lyrical," though it does not seem in any usual sense to include epigram, satire, or didactic poems.

The different classes of poetry are further treated of under the heads —BALLAD, DRAMA, EPIC POETRY, LYRIC POETRY, ODE, &c.

POINDING, in the law of Scotland, is a process for enforcing payment of a debt, against the property of the debtor. It is divided into "personal poinding," and "poinding of the ground." The former is the method by which any ordinary creditor attaches the moveables of his debtor; the latter is peculiar to the holders of real rights over estates belonging to others—as to superiors entitled to feu duties or the holders of real securities entitled to payment of the interest—who can by this process attach the rents or other proceeds of the estate, and pay themselves. Personal poinding is the most usual form—it is of very frequent occurrence, and is a rapid and effective process, analogous to the "distress" of the law of England.

POINT, in Music. [FUGUE.]

POINT. [SOLID, SURFACE, LINE, POINT, DEFINITION OF.]

POINT OF CONTRARY FLEXURE. By this term is understood a point at which a curve changes its curvature with respect to any given external point, being concave on one side and convex on the other. [See the figure in CURVE for instances.]

The mathematical test of a point of contrary flexure in a plane curve is as follows:—Let $y=\phi x$ be the equation of the curve, and let y'' be the second differential coefficient of y with respect to x. As long as y and y'' have the same sign, the curve presents its convexity to the axis of x; and when y and y'' have different signs, its concavity. When y'' changes sign, there is a point of contrary flexure, if y be then finite; and this, whether it passes through zero or infinity at the change. (Library of Useful Knowledge, 'Diff. Calc.,' pp. 369, 370.)

It is frequently stated in elementary works, that there is a point of contrary flexure when $y''=0$, and the converse. Both propositions are inaccurate. there is not necessarily such a point when $y''=0$, and there may be such a point when y'' is not nothing, but infinite.

For example, let $y=x^2-\frac{1}{x}$, which gives $y''=2-\frac{2}{x^3}$ As long as x is less than 1, y'' is negative, and so is y, whence the curve is convex to the axis of x. When $x=1$, both y and y'' vanish, and when x is greater than 1, y and y'' are both positive, so that the curve is still convex. But there is a change of sign in y'' when x passes through 1; and therefore there is a point of contrary flexure when $x=1$. It is to be remembered that though at a point of contrary flexure the curve changes curvature with respect to any line not passing through the point, it preserves its curvature with respect to every line which does pass through the point, being on both sides convex, or on both sides concave, to that line. In the present instance, the curve is always convex to the axis of x; consequently, where it has a point of contrary flexure, it cuts that axis.

At every point of contrary flexure, the TANGENT passes through the curve, and has a contact of an order different from that which it usually has. The radius of curvature at a point of contrary flexure is always either nothing or infinite.

Some English writers have copied the Continental ones in calling it a point of *inflexion*.

POISON. Separate articles having been devoted to nearly all the substances which are destructive to life when taken by accident or design, or when administered with a criminal intention, it will be necessary here only to consider the subject of poisons generally, referring to the articles ARSENIC, ANTIMONY, COPPER, MERCURY, PAPAVER, &c., for the details relating to each of them in particular. The whole subject may be conveniently and usefully treated by pointing out how in any case of legal investigation the proofs of poisoning may be established.

Omitting those things which are common to all cases of suicide or homicide, such as the previous circumstances of the person supposed to be poisoned, the conduct of the accused, and those, however important they may be, that are matters of common evidence, such as a number of persons who have partaken of the same meal being simultaneously and similarly affected, we propose to consider here only how in any individual case the influence of poison may be proved. The chief circumstances in the evidence will be, the symptoms presented during life: the examination of the body after death; the chemical analysis of the substances in which the poison may be mixed; and the experiments by which it is attempted to produce similar circumstances in animals by similar means.

The circumstances that usually first excite the suspicion of poison having been taken are, that the person affected is suddenly attacked by symptoms of severe illness, which come on soon after eating or drinking, without any premonitory indications, which regularly increase in severity without undergoing any important change in their character, and which rapidly prove fatal. All these however are far from affording sufficient evidence of poisoning. Suddenness of attack is common to many disorders, as cholera (whether ordinary or Asiatic), plague, perforating ulceration of the digestive canal, apoplexy, and epilepsy; and even in some cases of fever the premonitory symptoms are too slight to attract the attention of the patient. Any of these too may come on soon after taking food, and while the patient is apparently in the enjoyment of health; this is especially the case with cholera, perforation of the stomach, and apoplexy; and even in some diseases of the heart the patient may seem well up to the instant of the fatal, and often instantly fatal, seizure. The permanency and regular increase of the symptoms is not a more distinctive sign of poisoning. It is equally observed in many cases of the diseases already mentioned, as well as in most acute and uncontrolled inflammations, strangulation or other obstruction of the intestines, &c. Many of these diseases also may prove very rapidly fatal; apoplexy and certain diseases of the heart sometimes destroy life in a few seconds, and often in a few hours; in almost all cases of perforation of the digestive canal, and in some of cholera, death takes place in less than twelve hours.

In no case therefore can these, which are commonly stated as general symptoms of poisoning, excite more than suspicion; they may all have been produced by some spontaneously occurring disease. But on the other hand, the absence of any or all of them is not sufficient to disprove the suspicion of poisoning. Small and often repeated doses of poison may be given so as to produce all their symptoms and death very gradually; and the patient may in such a case exhibit numerous alternations of increase and moderation of the symptoms. Many circumstances will retard the action of even large doses of poison; if a person falls asleep soon after taking one, or if he has taken it with a large quantity of food, or much diluted, or partially neutralised, its symptoms may not be developed for some hours, and may seem quite unconnected with the last occasion of taking food. Or again, the poison may be administered in some other way than with food or medicine, as in the form of a vapour, by applications to the ulcerated skin, &c.

Dr. Christison divides poisons into three classes, irritants, narcotics, and narcotico-acrids. Each of these produce certain symptoms in addition to those already mentioned as belonging to poisons of all kinds, and certain morbid effects upon the organs of the body when it proves fatal, by which their action may in some cases be recognised.

The chief symptoms caused by the internal administration of irritant poisons are those of severe irritation of some or all parts of the alimentary canal. They commonly excite burning heat, redness and swelling and sometimes ulceration of the lining of the mouth, throat, and tongue; difficulty of swallowing, burning pain of the stomach with nausea and retching or vomiting, tenderness on pressure and tension of the upper part of the abdomen. The matters vomited consist, first, of the food or other contents of the stomach, and afterwards of tough mucus with more or less of blood and bile; the sickness is almost incessant, and is usually accompanied by severe suffering. The pain commonly extends from the stomach along a part or the whole of the digestive canal, with tenderness on pressure, and usually a constant and painful diarrhœa of mucus with more or less blood. The pulse is quick and feeble; there is great prostration of strength, excessive burning thirst, cold and damp skin, extreme anxiety of countenance and manner, and often considerable difficulty of breathing.

Many or all of these symptoms occur in all cases of poisoning by irritants, and many of them also in certain diseases, between which and poisoning it may be difficult to discriminate. Of these diseases the most important and deceptive are the acute affections of the digestive organs.

The most general effect of irritant poisoning is acute inflammation of the stomach, and it is therefore a question of the first importance whether that condition is ever produced by any other cause than the administration of poison. M. Louis and Dr. Abercrombie, whose authority is of the greatest weight in subjects of this kind, have stated that they never saw a case of idiopathic and primary acute gastritis; and it is certain that no well-established case of the kind has yet been recorded: the administration of an irritant poison may therefore be regarded as highly probable in any case in which a competent observer finds the signs of an acute inflammation of the stomach during life and its effects after death.

In such cases the principal evidence would depend on the appearances found in the dead body; in others the symptoms during life are equally important. Perhaps of all the diseases which give rise to the suspicion of irritant poisoning, the most frequent is cholera. There are however some circumstances by which they may be distinguished during life. In most cases of this kind of poisoning a burning sensation in the throat is perceived directly after the poison is taken, being the effect of its contact during or soon after the act of swallowing; the same symptom, when it occurs in cholera, appears to be produced by the contact of the substances vomited, and is therefore preceded by some of the other symptoms. In cholera the vomiting is never bloody, and is usually much more profuse than in cases of poisoning; and the cholera that occurs in this country is very rarely fatal in less than three days; while in most cases of poisoning, in which the symptoms are sudden and severe, death ensue in a few hours, or at least before the end of the third day. Asiatic cholera indeed is commonly more rapidly fatal, sometimes in four hours: but it may be distinguished by the absence or late occurrence of the burning pain of the throat, by the absence of vomiting of blood, by the peculiar expression of the countenance and condition of the body, and by the suppression of all the secretions except the characteristic discharges from the stomach and intestines. [CHOLERA.]

The symptoms of common peritonitis and of common acute entiritis [PERITONITIS; ENTIRITIS] can scarcely lead a competent witness of them to suspect that they arise from poisoning. But those of peritonitis from rupture or ulcerative perforation of any of the abdominal organs may closely resemble them, and render a diagnosis very ambiguous without the evidence of a post-mortem examination. Very severe cases of colic may also for a time simulate the effects of poison; but the frequent intermission of their symptoms, the absence of both the local and the general signs of inflammation, and their rarely dangerous character or fatal termination, are sufficient signs of distinction. In the cases which have been called ileus, and regarded by some as merely examples of severe colic, there may be some doubt till the examination after death shows them to have resulted from an obstruction of the intestinal canal [ILEUS]; and in ileus the pain is almost always round or near the umbilicus.

Other cases which are usually mentioned as simulating the effects of irritant poisoning are those in which the stomach having been greatly distended by gluttonous feeding, death has occurred suddenly from apoplexy or some unknown influence; and those in which death occurs from drinking cold water while over-heated. In the former cases death, if not produced by distinct apoplexy, is preceded by symptoms more like those of narcotic than those of irritating poison; in the latter, the symptoms are very like those of common cholera, and are in the same respects different from those of poison.

It is evident from these circumstances, that in a fatal case of suspected poisoning by an irritant substance, it will seldom be possible to decide upon the evidence of the symptoms alone. When poison has actually been taken, the symptoms are sometimes so modified by circumstances peculiar to the case, that even where they have been carefully observed, much doubt has remained respecting their cause: and, on the other hand, the symptoms of naturally excited disease often too closely resemble those of poison to permit a positive conclusion being arrived at. Cases very rarely occur in which (unless other circumstances not connected with the condition of the patient after the seizure are conclusive) the evidence of post-mortem examination is not absolutely necessary.

The most general morbid appearances produced by the irritant poisons are either the destruction, by corrosion, of the tissues over which they pass, or some of the effects of acute inflammation in them. Of the latter, that which is the least decisive is the most common—redness. In the stomach, no kind or degree of merely vascular redness of the mucous membrane can alone certainly prove that it has been inflamed. The most intense redness is sometimes found where the person has had no gastric affection, and may be produced in any part of the stomach by the blood settling in its vessels after death, or being obstructed in them by suffocation. It is probable also that any very slight irritant, such as wine, given shortly before death, may produce considerable redness of the stomach. Small quantities of blood may also be effused between the lining of the stomach, from any of the causes which produce general diffused redness of the mucous membrane, by congestion of its vessels; but more considerable effusions of blood, especially when they appear as if incorporated with the tissue, and are of a brown or black colour, as if charred, are almost certain signs of poison. Any appearance of blackness, or of a dark brown discolouration of the stomach, as if from a chemical change in the blood filling its small vessels, is also a very suspicious, though not a certain sign. But pills of aloes and sulphuric acid, prescribed for painters' cholic, produce this appearance in the stomach, if given a few hours before death. When redness of any part, or of the whole of the lining of the stomach is accompanied by the secretion of a large quantity of tough mucus upon it, it may be deemed suspicious, but it is by no means a conclusive evidence of poison; it is more nearly so when the mucus is stained or streaked with blood. An effusion of lymph on the lining of the reddened or blackened stomach is decisive of inflammation; and of poisoning, if, as is most probable, acute inflammation of the stomach never arises from natural causes. The effusion of lymph, however, is not a common effect of poison, and tough mucus is often mistaken for it; they may be distinguished by the former being ropy, glaring, and transparent, the latter opaque, white, and deposited in a tender brittle membrane or in irregular flocculi. The softening of the mucous membrane of the stomach, and the ease with which it may be separated from the subjacent tissues, are signs of inflammation, when combined with an intense bright redness, or the effusion of much mucus or lymph; without coincident redness they are not to be depended on, since they may result from the digestion of the walls of the stomach, which sometimes takes place after death by the action of the gastric juice. An increase of thickness in the mucous and other membranes, by the effusion of serum beneath them, is a suspicious but far from a conclusive sign of acute inflammation.

The more serious changes resulting from poisons, such as ulcers and perforations of the stomach, differ according as they have been produced by the corroding power of the substance taken, or by the inflammation which it has excited. In the case of corroding substances, a principal sign by which their effects would be distinguished from ulcers which are the results of disease, is, that every part of the digestive canal with which poison has come in contact is affected at the same time, the lips, mouth, œsophagus, stomach, and even the intestines, all showing more or less of their influence; whereas it is very rare for diseases to affect more than one of these parts at a time. The appearance of an ulcer, or a perforation of the stomach, produced by corrosion, is also peculiar; it is commonly large and irregular; its edges are soft and pulpy, and usually black or brown, as if charred; and if the patient has survived only an hour or two, signs of acute inflammation will be seen in its neighbourhood, and in all the parts to which the corroding material has obtained access. Similar signs of acute inflammation are also always observed in the ulceration or perforation which sometimes, but very rarely, is produced by poisons that merely irritate the digestive canal; and these are a part of the signs by which those effects of poison are to be distinguished from perforations that occur naturally.

Ulceration and perforation of the stomach are so rarely the effect of merely irritant poison, and so commonly the effect of disease, that, unless there be signs of corrosion, they afford evidence against, rather than for, the suspicion of poison; and if there be no other evidence, and no attendant sign of recent acute inflammation, they may even be regarded as proofs that such a suspicion is incorrect. Of the forms of perforation of the stomach from other circumstances than poisoning, one of the most important is that in which, without any material alteration in the surrounding parts, one or more small ulcers form in the stomach, and becoming gradually deeper, at last, by a minute aperture, make their way through its walls, and permit its contents to escape slowly into the abdomen. These may be known at once to be the effects of disease, by the complete absence of any sign of inflammation in the lining or other tissue around them. Another form is accompanied with thickening of a considerable extent of the tissues adjacent to the ulcer, which is from a quarter to half an inch in diameter, and perforates by a large orifice, forming a hole with smooth edges, as if a piece of the stomach had been cut out by a sharp instrument. The thickening around the ulcer, which has all the characters of chronic inflammation, and the appearance of even a commencement of cicatrisation, with the absence of all signs of acute disease of the stomach, are usually quite sufficient to distinguish this form of perforation. A third, which can scarcely give rise to doubt, is that consequent on cancerous or other malignant disease of the stomach. A fourth is that in which a portion of the walls of the stomach is dissolved or digested by the gastric juice after death; but whatever uncertainty there may be respecting the circumstances under which this singular effect is produced, there ought to be none in distinguishing it from the effects of poison.

From these statements it will appear that in some cases the symptoms and morbid appearances together may prove that irritating poison has been taken. The diseases in which the similarity of the symptoms is most embarrassing, as cholera and peritonitis, are those in which the morbid appearances are most distinct from perforation of the abdominal organs; while those more chronic inflammations of the stomach in which the morbid changes of structure are least decisive are those in which the symptoms admit of little doubt. This however cannot apply to all, though it may to the majority of cases. When death is produced slowly, the symptoms may be obscure, and the morbid changes very like those of disease: and still more difficult cases occur in which poison is taken by those who already suffered from disease of the stomach; or in similar individuals, deceptive appearances may be produced by the digestion and other changes in the stomach which occur after death. Cases of these kinds form a numerous class, in which the test of chemical examination, which indeed should be neglected in none, can alone be conclusive.

For this part of the subject however no general rules can be laid down. The detection of each poison must depend on the proper application of its appropriate tests; and these will be found in the several articles already referred to. [ARSENIC, &c.]

The symptoms produced by the different narcotic poisons are more varied than those of the irritant class. The most common are giddiness, headache, obscurity or depravation of the sight, stupor or perfect insensibility, loss of power of the voluntary muscles, or convulsions of various kinds, and, towards the close, complete coma. To these the several species of narcotic poisons add effects peculiar to themselves; yet not so remarkable but that they are closely simulated by those of some naturally occurring diseases. The symptoms of apoplexy, for example, are almost exactly similar to those of poisoning by opium and the substances allied to it. In certain cases however the following circumstances may distinguish them. Apoplexy, though its actual attack is sudden (which the effects of opium are not), is often preceded by warning symptoms, such as headache, occasional giddiness, &c. If so severe as to simulate poisoning, it is not possible to arouse the patient from his stupor; but in poisoning with opium this may usually be effected to within a few hours of death; in apoplexy, convulsions often occur, in poisoning with opium, never; in the former the pupil is commonly dilated, in the latter contracted. Narcotic poisoning, if not fatal in twelve hours, is usually recovered from; apoplexy often terminates fatally after several days.

These distinctions will seldom serve further than to establish a very probable conclusion; and doubt may still remain in cases of this kind after a post-mortem examination. The evidence of poisoning afforded by it is commonly negative; the fullness of the vessels of the brain and the other slight differences from the appearances found in the average of healthy persons, that are commonly quoted as signs of the effects of narcotic poisons, are very unsatisfactory. It is probable that narcotics destroy by producing a kind of apoplexy; and in many cases the changes of structure to which they lead exactly resemble those of that disease, whether of those cases of it which are attended with effusion of blood in or upon the brain, or of those in which only the least possible alteration from the healthy structure can be detected. [APOPLEXY.] Effusion of blood in the brain, however, is very rarely the effect of narcotic poisoning, and such an appearance would by itself afford strong evidence of apoplexy the result of disease.

The symptoms of epilepsy are often very like those of poisoning by prussic acid, and by some other narcotic and narcotico-acrid poisons, as belladonna, strychnia, &c. The following circumstances, however, distinguish epilepsy: the fit is often preceded by warnings; it almost always commences suddenly and violently; the patient cannot be roused from it; when fatal (which it very rarely is in a first attack), it is so only after several hours. In many cases the post-mortem examinations of epileptic patients detect no signs of disease; and in these there must always be some doubt, as this negative character is common to them and to narcotic poisoning. But in many, traces of old disease in the brain are found, which of course afford strong presumptive evidence that poison has not been taken. If a patient has died in a fit resembling those of epilepsy, and no morbid changes are found in his brain, poison must be strongly suspected; because it is very rare for such a fit, the result of disease, to terminate fatally, except in those whose brains are previously much diseased.

It is only necessary to allude to the difficulty that may at their first access exist, of distinguishing between the acute inflammatory diseases of the brain and those of the narcotico-acrid and some of the narcotic poisons. The true nature of the case is almost always evident after the first day of its duration; the poisoning is by that time terminated either by recovery or death; the disease continues its progress; and if the latter ends fatally, the morbid changes that it induces are sufficiently characteristic.

On the whole it must be concluded that the evidence afforded by symptoms and morbid appearances is less frequently conclusive in cases of poisoning by narcotics than in those where it is produced by irritants. The effects of the narcotico-acrids, which are compounded of those of the two other classes, are also in most cases as uncertain as those of the narcotics, and the difficulty with them is much increased by the present imperfection of the chemical tests of their presence in organic mixtures.

The evidence to be drawn from experiments with the substances supposed to contain the poison can rarely be needed, or be of much weight when obtained. In any case in which there is sufficient poison present to produce symptoms in any animal to which it is given, it ought to be discovered by the much more certain test of chemical analysis. This last, the evidence of chemistry, is certainly the least fallible of all, and in cases in which it can be applied it is generally conclusive. These cases include the great majority of those of poisoning by irritants, and many of those by narcotics and narcotico-acrids; but in many of those by the two last classes, owing to the present imperfection of the tests for organic poisons, it is unavailing even in the most competent hands. In these also, as we have already shown, the evidence of symptoms and of the morbid appearances is also often fallacious; and cases must frequently occur in which the evidence from all these sources together will not constitute a proof that poison has been taken. In the case of irritant poisons, on the other hand, the cases are few in which, from one or other of these kinds of evidence, their administration may not be satisfactorily proved.

We subjoin a list of the substances which should be administered in cases of poisoning, as early as possible after it has been swallowed:—

Mineral acids (*sulphuric, muriatic, &c.*).—Chalk [*] or magnesia in water; soap and water, and afterwards milk and other diluents.

Alkalies (*soda and potash*).—Vinegar and water; almond or olive oil; any innocent acid, such as lemon-juice, with water.

Oxalic acid.—Large quantities of chalk or magnesia; afterwards milk and other mild fluids.

Arsenic.—Powerful emetics, such as sulphate of zinc, if vomiting has not commenced; large quantities of milk, or some thick bland fluid, such as flour and water, or sugar and water.

Corrosive sublimate and other compounds of mercury.—White of eggs beaten up with water; decoction of bark or gall-nuts, or strong tea.

Blue vitriol and other compounds of copper.—White of eggs with water; sugar and water.

Antimony.—Large quantities of warm water or milk; decoction of bark or gall-nuts.

Nitrate of silver (*lunar caustic*).—Common salt and water.

White vitriol and other compounds of zinc.—Milk; carbonate of soda in water.

Compounds of lead.—Emetics, sulphates or bi-carbonates of soda or potash in water; milk.

Laudanum and other preparations of opium.—Emetics; dashing of cold water on the face; strong coffee; forced exercise by constant walking.

Prussic acid.—Hartshorn, to be smelled and taken in small doses; chlorine; dashing with cold water.

Strychnine and other vegetable alkalies.—Emetics; warm water; decoction of bark or of gall-nuts.

For other, as for many of these kinds of poison, it will always be right to excite copious vomiting, either by tickling the throat or by giving a powerful emetic, such as from ten to twelve grains of sulphate of zinc (white vitriol), or the same quantity of powdered ipecacuan with one or two grains of tartarised antimony. The action of the emetic should be maintained till all the poison seems to be discharged, by repeated draughts of milk, or flour and water, or sugar and water, or some other bland fluid. But for narcotic poisons the stomach-pump is best. For the subsequent treatment no general rules can be given.

POISONING, SECRET. When the knowledge of the nature of mineral, vegetable, and animal compounds was less known than at present, it was not uncommon for individuals to become acquainted with the poisonous properties of bodies, and to keep this a secret for the purpose of exercising a control over the lives of their fellow creatures. The entire ignorance that existed of the means of ascertaining the presence of poisons, or of the systems of poisoning as distinguished from other diseases, gave to persons who had accidentally discovered a poison a great power, and offered a temptation to crime. In ancient history many instances are recorded of persons who died under suspicious circumstances, and who were supposed to have been secretly poisoned. Beck, in his 'Medical Jurisprudence,' says that "Theophrastus speaks of a poison prepared from aconite which could be moderated in such a manner as to have effect in two or three years, or at the end of a year or two years; and he also relates that Thrasyas had discovered a method of preparing from other plants a poison which, given in small doses, occasioned an easy but certain death without any pain, and which might be kept back for a long time without causing weakness or corruption. This last poison was much used at Rome about two hundred years before the Christian era." During the reigns of Caligula, Claudius, and Nero, a woman named Locusta seems to have been frequently employed for the purpose of administering poisons, whose powers were known to herself alone. Locusta was employed by the second Agrippina to poison her husband the emperor Claudius, and also by Nero to poison Britannicus, the son of Claudius and Messalina. (Tacitus, 'Annal.,' xii. 66; xiii. 15.)

The poisons used by the Greeks and Romans seem to have belonged principally to the vegetable kingdom, and were chiefly obtained, it is supposed, from the aconite, hemlock, and poppy. One of their animal poisons is said to have been the acrid juice secreted by a species of *Tectibranchiate mollusca*, called the sea-hare, the *Aplysia depilans* of Linnæus. They did not seem to be acquainted with mineral poisons.

In modern times secret poisoning has often been carried on to a great extent; although the relation of many of the incidents has been so connected with superstition, and a belief in supernatural powers, that it is sometimes difficult to distinguish between the true and fictitious. The aid of poisons appears sometimes to have been resorted to in order to obtain credence for the powers of the witch and the wizard. A singular combination of poisoners was discovered at Rome during the pontificate of Alexander VII. in 1659. It was observed that many young married women became widows, and that many husbands died who were known to have become disagreeable to their wives. Great exertions were used to detect the poisoners, when at length suspicion fell upon a society of young wives, whose president was an old woman who pretended to foretell future events, and who had often predicted very accurately the death of many persons. At length the society was detected, arrested, and every member put to the torture, and the old president, by name Spara, and four others, were publicly hanged. It appeared that Spara was a pupil of Tofania, an infamous woman who lived at Palermo, and afterwards at Naples. The poison used by Tofania went by the name of Aqua Tofana [AQUA TOFANA], but its composition was never accurately made known.

The practice of secret poisoning was carried to a great extent in France about the year 1670. One of the most distinguished agents in this business was Margaret d'Aubray, wife of the Marquess de Brinvilliers. She formed an improper intimacy with a villain named Sainte Croix, who taught her the art of poisoning, which she put in practice in order to better her circumstances. For the purpose of ascertaining the strength and action of her poisons, she assumed the dress of a nun, and distributed food to the poor, nursed the sick in the Hôtel Dieu, and administered to them her poisons. She poisoned her father and brother, but was at last discovered. She was publicly beheaded in Paris on the 16th of July, 1676. She left behind her a complete catalogue of all her crimes. The principal poison used by herself and accomplices was the corrosive sublimate. The practice at this time had extended so widely in France that the government thought it necessary in 1679 to institute a court under the title of Chambre de

---

[*] In any cases in which chalk is recommended, the plaster of the ceiling or walls of a room rubbed into powder and mixed pretty thickly with water may be used with equal advantage.

Poison, or Chambre Ardente. The powers of this court, however, were abused, and very shortly after its institution it was suppressed.

Wherever evidence has been left sufficiently positive to admit of an inquiry into the nature of these secret poisons, it has been found that they contain ingredients well known at the present day. It is only where the sciences of chemistry and medicine are not sufficiently known, or where they are neglected in the inquiry, that secret poisoning can take place. The tests are now so accurate, and the investigations so strict, that it is no longer possible to administer any poison, vegetable or mineral, of which traces cannot be discovered in the body of the person poisoned, though of course it may not always lead to the discovery of the person by whom it was administered.

(Beckmann, *History of Inventions*; Beck, *Medical Jurisprudence*; Adams, *Edinburgh Medical and Surgical Journal*, vol. xxxiii.)

POLAR CLOCK. A portion of the light which passes to the earth under a sky which is clear, or nearly so, is more or less polarised. The maximum effect occurs in a plane passing through the earth's axis at 90° from the sun: hence the amount of polarisation varies in different parts of the sky with the position of the sun. On this relation between the hour-angle and the plane of polarisation of light from the sky, Professor Wheatstone has based his polar clock. It consists of a tube, with the axis parallel to that of the earth passing with gentle friction through an hour-dial. Within the tube is a polarising apparatus, which indicates the position of the plane of polarisation by the vanishing of the coloured rays; and as the plane of polarisation is always 90° from the sun, the index hand attached to the tube, and properly adjusted, will always point to the hour on the disappearance of the colours. The dial is connected with an upright, which moves on a hinge joint, so that by means of a quadrant and a clamping screw it can be adjusted to the latitude of the place of observation.

POLAR LIGHTS. This subject, that of the *Aurora Borealis* and *Australis*, will be treated of under the appellation in which they were included by Humboldt, TERRESTRIAL LIGHT.

POLARITY signifies, in general, a disposition in a body or in an elementary molecule of a body to place its mathematical axis in some particular direction; frequently also it denotes in a body the existence, either naturally or induced, of two points possessing contrary properties.

If iron-filings be strewed over a mass of natural loadstone, it will be found that there are two points on its surface at which the filings are most abundantly attracted, and where they dispose themselves nearly in the direction of a line imagined to be drawn through the mass [MAGNETISM.] Then, if the loadstone be cut in the form of a sphere, having this line for a diameter, the symmetrical arrangement of the iron-filings with respect to this line affords an indication that the particles of the loadstone may be symmetrically disposed about the line; and, from an analogy with the axis and poles of the earth, this line is called the axis of the loadstone, and its extremities are called the poles. If the mass of loadstone be cut in the form of a prism, the length of the latter being in the direction of the axis, and if the prism be suspended by its centre of gravity, it will be found to take one particular direction with respect to the horizon and the meridian of the observer. The two extremities of the prism so formed have received the denomination of poles, and the term is now applied to the opposite extremities of any body or molecule, when it assumes or can be brought into a particular direction.

What has been said respecting the properties of a prism formed of the natural loadstone, is true of a magnetised bar of steel [MAGNET], and the poles or opposite extremities of either material are found to possess a contrariety of character. One extremity always tends towards the northern part of the horizon only, and the other towards the southern part; and if two such prisms or bars are formed, and suspended by their centres of gravity, on bringing the northern or southern pole of one near the like pole of the other, they exercise upon each other a mutual repulsion; but if either pole of one be brought near the opposite pole of the other, they mutually attract each other.

Since in magnetised bars the poles of contrary names thus attract each other, and that the earth may be considered as a body possessing boreal magnetism towards the north, and austral magnetism towards the south, it is evident that the magnetism which exists in the northern extremity or pole of a suspended bar (as a compass needle) must be *austral*, and that which exists in the southern extremity must be *boreal*.

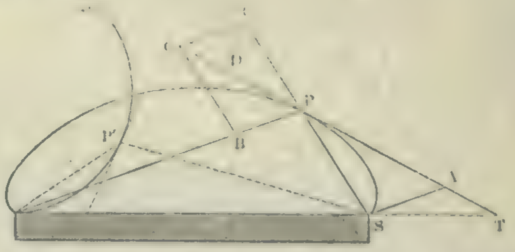
If a cylinder of wood or metal be insulated on a glass stand, and it be then brought near a body which has been electrified by the usual machine, it will be rendered polar; that is, one end will possess the vitreous or positive electricity, and the other the resinous or negative electricity, and near the middle the cylinder will be in a neutral state. These conditions may be rendered evident on electrifying a pith ball, insulated by means of a silk thread, and presenting it to the cylinder, when it will be attracted towards one end and repelled from the other. It appears, from the effect of the cylinder on the electrified ball, that the particles of fluid of the same kind repel each other, and those of unlike kinds attract each other.

Polarity is also obtained by galvanic electricity. In an ordinary battery, the fluid, by chemical action on the zinc, produces a separation of the two kinds of electricity; that which is called positive is carried to the copper plate, and the latter communicates it to the zinc plate with which it is connected. This action is repeated at every pair of plates in the battery; and from the last zinc plate the electricity enters the conducting wire, or that which is employed to connect the opposite extremities of the battery: thus the zinc extremity constitutes the positive pole of the battery. At the same time an opposing current of negative electricity passes from the copper, through the fluid, to the zinc, from thence to the next copper plate, and so on to the last, which is in connection with the conducting wire at that extremity of the battery; this copper end is called the negative pole of the battery. [GALVANISM.]

The attractive power in a magnetised steel bar increases from each extremity to about one-quarter of an inch from thence, where it is the greatest, and it then diminishes gradually towards the centre; this distribution is similar to that of the induced electricity in the insulated cylinder. But experiments show that if a prism of loadstone or a magnetised bar be divided into several parts, perpendicularly to its length, each part is a complete magnet, having poles of contrary denominations at its extremities; and this condition is accounted for by Coulomb in the following manner:—He supposes that every molecule of loadstone is a small magnet possessing opposite polarities at its extremities, the axes of all being parallel to or coincident with the magnetic axis of the mass; and that a similar disposition of the molecule is induced in a bar of steel when the magnetic power is communicated to it. The austral polarity of each molecule, while in the mass, is destroyed by the boreal polarity of that which is contiguous to it in the common directions of their axes; but on separating, as above, the parts of the loadstone or magnetised bar, that extremity of each which is farthest from the northern pole of the bar exhibits the austral magnetism appertaining to the like extremities of the molecules; and that extremity which is nearest exhibits boreal magnetism.

A magnetised steel bar, when tried by means of a small compass-needle, is often found to exhibit, at different places in the direction of its length, a change from boreal to austral magnetism, and the contrary. These places are called consecutive poles.

The intensity of the force, either of attraction or repulsion, exercised by one of the poles of a magnet on any body is inversely proportional to the square of the distance of such body from that pole; and if a very small compass-needle, supported or suspended in the usual way, be brought near a magnetised bar, it must settle, between those opposing forces, in the direction of a tangent to some curve line passing through the two poles of the magnet. This is called the magnetic curve, and the direction of the tangent at any given point may be thus investigated:—



Let N be the north and S the south pole of a magnet; let P be any given point at which the centre of gravity of a small suspended needle may be placed, and join PN, PS. Let the attraction of N on P be expressed by $\frac{1}{PN^2}$ and be represented by PB; also let the repulsion exercised by S on P be expressed by $\frac{1}{PS^2}$, and be represented by PC, in the direction of SP produced. Imagine the parallelogram CB to be formed; then, by mechanics, PQ, its diagonal, will represent the resultant of the forces acting on a particle at P; it will therefore be the direction of the needle and of a tangent to the curve at that point. Let $\angle$ QPC be represented by θ; $\angle$ QPB by θ', and let fall CD perpendicularly on PQ: then by trigonometry, $\frac{\cos.\theta}{PS^2}$ is the value of PD, or the equivalent of the force represented by PC when reduced to the direction PQ; and $\frac{\cos.\theta'}{PN^2}$ is the value of QD, or of the force PB (=QC) when reduced to the same direction. The sum of these, or $\frac{\cos.\theta}{PS^2} + \frac{\cos.\theta'}{PN^2}$, is the value of PQ, and represents the whole force of the magnet on the point P in the direction of that line: hence,

$$PQ^2 = \frac{\cos.^2\theta}{PS^4} + \frac{\cos.^2\theta'}{PN^4} + 2\frac{\cos.\theta\cos.\theta'}{PS^2.PN^2}.$$

But, by geometry, $PQ^2 = PC^2 - QC^2 + 2PQ.QD$ which, by substitution becomes $\frac{1}{PS^4} - \frac{1}{PN^4} + 2\left(\frac{\cos.\,\theta}{PS^2} + \frac{\cos.\,\theta'}{PN^2}\right)\frac{\cos.\,\theta'}{PN^2}$. Equating these values of PQ^2 and leaving out terms which destroy each other, we have $\frac{1}{PS^4} - \frac{\cos.^2\theta}{PS^4} = \frac{1}{PN^4} - \frac{\cos.^3\theta'}{PN}$; whence $\frac{\sin.\,\theta}{PS^2} = \frac{\sin.\,\theta'}{PN^2}$, and $\sin.\,\theta : \sin.\,\theta' :: PS^2 : PN^2$.

Now, produce QP till it meets NS, produced, if necessary, in T; and draw SA parallel to NP: then, by trigonometry,

$$SA : PS :: \sin.\,APS : \sin.\,PAS :: \sin.\,QPS : \sin.\,QPN;\text{ that is,}$$

$$SA : PS :: \sin.\,\theta : \sin.\,\theta';\text{ hence}$$

$SA : PS :: PS^2 : PN^2$, which being compounded with the identical proportion $PS : PN :: PS : PN$ gives

$$SA : PN :: PS^3 : PN^3.$$

But SA being parallel to PN, $SA : PN :: ST : NT$; therefore $ST : NT :: PS^3 : PN^3$.

Thus the ratio of ST to NT is known; and, consequently the position of the tangent PT, from the given position of P. If the poles N and S are unlike, as above supposed, the curves are of the kind called convergent, as NPS; but if the poles are similar, the curves will be divergent, as $NP'S'$.

POLARIZATION OF LIGHT,
POLARIZATION, MOVEABLE,
POLARIZED RINGS, } will be found at the end of letter P.

POLDERS. The meadow lands by the side of rivers, or of the sea-shore, which are only protected from inundation by means of enclosure dykes, banks, or walls, are known on the Continent by the name of Polders; and in Holland, where these hydraulic works are the most common, they are further subdivided into the schorres, the maritime polders, the boezem landen, and the drained lakes. The various works connected with these modifications of polders will be discussed under RIVER ENGINEERING, and SEA DEFENCES. For the present, it may suffice to say that the polders almost invariably require a complete enclosure, with an interior collecting drain for the land waters, which are discharged directly through sluices, or outfall gates, or are lifted over the bank by windmills or other mechanical means. The polders are, generally speaking, used as grazing land for horned cattle, or at times for the growth of rape or other oleaginous grains: of course the cattle are withdrawn from them during the winter months. The superintendence of the works for the defence and maintenance of the polders in North-Western Europe is entrusted to local administrations, or syndicates, acting under the control of the respective departments of public works in the countries where those polders exist.

POLE. [PERCH.]

POLE, POLAR. The word πόλος as applied to a point means a turning or hinge point, and was applied to the points at the extremity of the axis of the celestial sphere in the ancient astronomy. Hence, on the hypothesis of the earth's rotation, it comes to mean the extremities of the axis on which the earth turns. From this primary meaning all the various uses of the word pole have been derived. For example, when it was found that the magnet did not always point to the north pole, but to another point, it was natural to call that other point the *magnetic* pole. Previously to this use of the word, it had already taken a wider signification, as follows:—On looking at the position of the equator with respect to the poles, it is obvious that if the equator, or circle of equal day and night, should be changed, the axis must also be changed, and the poles of rotation. Hence any great circle of the sphere is said to have its poles, meaning those points which would become poles of rotation if that circle became the equator. [SPHERE.]

A term seldom passes through several significations, however nearly related, without at last becoming generic in the widest sense. The word pole is now used to denote any point which is of so striking a character as to require a distinct name. In physics the word is naturalised in magnetism, electricity, and optics; insomuch that any tendency towards a particular point, or even towards a particular direction, is termed polarity. In geometry, the only definition which can now be given of this term is, that it means any point which it is wanted to mean. Thus a point considered as the origin of CO-ORDINATES is called the pole; and when distances measured from the origin are among the co-ordinates, they are called polar. Again, it is a well known property of the conic sections, that if all possible chords be drawn through any one given point, and a pair of tangents be drawn from the extremities of each chord, the intersections of all the pairs will lie in one straight line; the point through which the chords are drawn is called the pole of that straight line.

POLE STAR. [URSA MINOR.]

POLEMARCH. [ARCHON.]

POLICE is that department of government which has for its object to secure the safety, peace, and convenience of the community. We have here to do with this its primary object, namely, the prevention of crime and the pursuit of offenders; but besides this the police system is subservient to other purposes, such as the suppression of mendicancy, the preservation of order in great thoroughfares, the removal of obstructions and nuisances, and the enforcing of those local and general laws which relate to the public health and comfort. [MUNICIPAL CORPORATIONS.]

In the Anglo-Saxon times the whole community was called upon to aid in protecting life and property; and the spirit of this system, though the system is no longer applicable to the existing state of society, still characterises this department of our institutions. The object of the present notice will be to give some account of the former and present constitution of the police in England.

In the Anglo-Saxon period the sheriff of each county, chosen by the freeholders in the folkmote, was the chief officer responsible for the conservation of the peace; and in his half-yearly visitations to each hundred in the county, he inquired whether there was any relaxation in the efficiency of the means in use for this object. The hundred originally consisted of ten divisions, each containing ten freeholders, mutually pledged to repress delinquencies within their district. All males above the age of twelve were obliged to appear at the sheriff's visitation, to state the district to which they belonged, and to be sworn to keep the peace. One out of every ten freeholders had precedency of his companions, and the whole were bound to bring delinquents to justice within thirty days on pain of being themselves liable to penalties. The population was thinly scattered; every man was known to his neighbours; no man could depart from his dwelling without the consent of his fellow-pledges; and the consent of the sheriff was necessary to enable a man legally to go out of his own county. No man could enter a neighbourhood without being recognised as a stranger, and probably exciting suspicion; and this suspicion, quickened by the responsibility of the freeholders, soon caused a hue and cry if the stranger could give no good account of himself. [HUE AND CRY.]

After the Conquest, the advantages of the system were recognised by several of the Norman kings, particularly by William I., and by Henry I. in the early part of his reign. The former ordered that every freeman should be under pledges, and the latter that views of frank pledge should be taken in order that none might escape responsibility. But a great innovation was made in the Anglo-Saxon system when the sheriff, instead of being elected by the freeholders, was appointed directly by the king. Doubtless he would generally be a Norman, and therefore indisposed to meet the people in their popular courts: at all events the sheriff's "tourn," or half-yearly visitation, came in no long time to be neglected.

When Henry I. instituted the office of justices-itinerant [CONSERVATORS OF THE PEACE], the functions of the sheriff became of still less importance. By the stat. Merton, c. 10, passed 20th Henry III. (1236), freemen who owed suit to the county or hundred court were allowed to appear by attorney. The stat. Marl. cc. 10 and 25 passed in the 52 Henry III. (1268), dispensed with the attendance of the baronage and clergy at the sheriff's court unless their attendance was specially required; and it also prohibited the justices-itinerant from amercing townships on account of persons above the age of twelve years not having been sworn in pledges for keeping the peace. By these various measures the ancient system was greatly impaired; and the new laws which were introduced from time to time for the purpose of repressing crime do not seem to have been very successful. In 1277, nine years after the passing of the statute of Marlebridge, the absence of "quick and fresh pursuit" of felons is noticed as an evil which was increasing. To supply the energy and alacrity of the old system, fines and penalties were imposed by the stat. Westminster, prim. 3 Edward I., sec. 9, on all who neglected to pursue offenders. The statute directs that "all generally be ready and apparelled at the commandment and summons of the sheriffs, and at the cry of the county, to pursue and arrest any felons when any need is." The statute of Winchester, 13 Edward I. (1285), endeavoured to maintain the spirit of the Anglo-Saxon laws by making the county or hundred responsible in case of a delinquent not being forthcoming, and the duty of apprehending him was cast upon all the king's subjects. This statute also regulated the office of constable, an officer who had succeeded the Anglo-Saxon hundred or tything-man. [CONSTABLE.] The constables were directed what measures they were to take for preventing crime and keeping the peace. In every town, village, and tything they were to set a watch according to the size of the place, every night from Ascension till Michaelmas, from sunset to sunrise; and the watchmen were to apprehend and examine all strangers, and on their refusal to obey the summons of the watchmen, they might levy hue and cry to take them. The gates of all walled towns were to be shut from sunset to sunrise: the highways were to be kept clear of bushes, woods, or dykes for the space of two hundred feet from hedge to hedge, so that felons might not conceal themselves. Every man was to have arms in his house for preserving the peace; and the constables were empowered to take the view of such arms. The prevention of crime, as well as the pursuit of criminals, was also one of the primary duties of constables, and they were charged to make presentment at the assizes, sessions of the peace, or leet, of all blood-sheddings, affrays, outcries, rescues, and other offences against the peace. The justices to whom these presentments were made in the first instance, reported directly to the justices-itinerant, or at once to the king or his privy-council; and the supreme executive made provisions accordingly. At the same time the responsibility cast upon the hundred quickened the vigilance of the inhabitants; and this responsibility extended to individuals in many cases. The following extracts from the Year-Books of the Exchequer are instances of this: "16 Edward I., Sussex: murder and robbery—township of Tyndon amerced, because it happened by day, and they did not take the offender." "6 Edward II., Kent: manslaughter (upon a sudden quarrel) committed in the highway of Wrotham—three bystanders amerced because they were present when the aforesaid Robert killed the aforesaid John, and did not take him." And in the reign of Elizabeth the popular vigilance which this system had created leads a writer of that day to remark that "every Englishman is a serjeant to take the thief, and who showeth negligence therein do not only incur evil opinion thereof, but hardly shall escape punishment." Thus, when the Anglo-Saxon system of mutual protection had fallen to decay, the spirit of vigilance which characterised it was in some measure replaced by the greater energy and activity of the supreme executive. In process of time, however, great social and political, and, it may be added, physical changes have rendered both systems equally incapable of effecting the objects for which they were intended.

In the year 1829, the late Sir Robert Peel, after having consolidated the Criminal Law of England, instituted in the metropolis the new police force, which more than any other external means has consolidated peace and protected life and property, to the undoing of invective such as met its introduction, and to the disappointment of all the alarm that was excited by it for the liberty of the subject. This was effected by the 10 Geo. IV., c. 44; and that Act was followed by the 2 & 3 Vict. c. 47, making further improvements in the force, extending the metropolitan police district to a radius of fifteen miles from Charing Cross, and giving police-jurisdiction over the river Thames, and the quays and docks existing thereon. The city of London, that had been exempted from the operation of these statutes, was by the 2 & 3 Vict. c. xciv., provided with a similar force under a special commissioner, entirely under the control of the city authorities. And other cities and boroughs from this time forward successively acquired by private Act of Parliament the necessary powers to enable them to institute and maintain police on the model of the metropolitan force. By the 5 & 6 Vict. c. 109; 7 & 8 Vict. c. 52, and 13 & 14 Vict. c. 20, petty constables for preserving the peace in parishes or townships maintaining their own poor, and in extra-parochial places, are to be chosen annually by the justices of the peace for the district or division, from a list made by the overseers, comprising every able-bodied man between 25 and 55 years resident in the parish, and rated to the poor rate or county rate, or holding at the yearly rent of 4*l*., subject, however, to sundry exceptions expressly mentioned in the Act. This was a resuscitation of the ancient constabulary for the protection of life and property, and maintenance of the queen's peace, in places and districts not incorporated, the inhabitants themselves, in the true spirit of old English institutions, being thereby mutually engaged under oath, without remuneration, to the performance of this important public duty.

The 2 & 3 Vict. c. 93, and the 3 & 4 Vict. c. 88, had in the meantime provided for the appointment of county constabulary, clothed, paid and accoutred, and formed in accordance with rules prescribed by the Secretary of State for the Home Department. But as these Acts left the initiative in the discretion of the county magistrates, very many of the English and Welsh counties continued to be without protection, save such as was afforded by the parish constable, until the 19 & 20 Vict. c. 69 (20 Vict. c. 2) made it compulsory on the magistrates of every county where no police had yet been constituted, to proceed therein forthwith. Powers for the consolidation of independent bodies of police already existing, or for the joint appointment and superintendence of police for adjoining districts and boroughs, were given by the same statute, and provision was made for imposing one-fourth of the expense of the force, whenever it was efficient, on the Consolidated Fund. Similar provision had already been made by the 3 & 4 W. IV., c. 89, for advancing a sum of 60,000*l*. a year out of the Consolidated Fund towards defraying the expense of the metropolitan police. In this way the whole of the country, by successive steps, and in virtue of a series of statutes, beginning with the Act of Sir Robert Peel in the tenth year of George IV., has at length been placed under the protection of a well-devised and very efficient system of police, whose surveillance of the country is continued throughout the whole of the four-and-twenty hours. In Scotland the larger towns have many of them separate police statutes, placing the management and control of the system in the hands of elected commissioners; but the 3 & 4 Wm. IV. c. 46, a general police Act, the provisions of which, or a portion of them, might have been adopted by any royal burgh, burgh of regality, or burgh of barony, at a meeting of a specified number of ten-pound householders, has been adopted in several places. That Act was amended by the 10 & 11 Vict. c. 39, and further by the 13 & 14 Vict. c. 33, and, thus amended, is still in full force and operation. The 20 & 21 Vict. c. 72, however, has since been passed for improving the police system of Scotland, and providing facilities for the establishment of police where none at the time existed. As in the general Act for England, the institution of county constabularies is by this Act compulsory on the commissioners of supply for each county; provision is also made for the consolidation of independent bodies of police, and for the establishment of police for neighbouring districts and burghs jointly. The former statute, the 2 & 3 Vict. c. 65, which left it discretionary in the commissioners of supply to provide constables for the counties, is repealed; and provision is made for charging one-fourth of the expense of any burgh or county constabulary, reported to be efficient for the year in numbers and discipline, on the Consolidated Fund.

POLICY and POLITY. Policy is generally used to signify the line of conduct which the rulers of a nation adopt on particular questions, especially with regard to foreign countries; and according to our opinion of that particular line of conduct, we say that it is good or bad policy. Polity has a more extended sense, being synonymous with the principles of government, and this is the sense of the Greek "politeia" (πολιτεία), from which it is derived. Police, in an extended sense, is that branch of polity which is concerned with the internal economy of the state. In a more restricted sense, it is a branch of preventive administration, distinct from the administration of justice, the object of which, among other things, is the punishment of crimes committed.

POLICY. [Reversion.]

POLIENE. [Melam.]

POLISHING. [Cutlery; Gilding; Varnish.]

POLITICAL ECONOMY is the name given to a department of knowledge the limits of which are not yet accurately defined. The word economy, applied to domestic concerns, means the art of well administering the private affairs of a family, of regulating its expenditure according to its income, and providing for the wants of the members of the household. By analogy, political or "public" economy has been considered by many as conversant about the principles of administering the wealth of a country with a view to its increase, regulating the expenditure, providing for the wants of the people, and endeavouring to maintain and increase their comforts. But by taking such an extensive view of the subject, most writers, and especially continental writers, have considered it necessary to investigate all the causes of the prosperity of nations, and have involved themselves in multifarious discussions on the various forms of government and of civil institutions which are supposed to affect the economical condition of a people. By so doing they have encroached upon the science of general politics and legislation, and have brought forward their own theories of laws, ethics, and administration, with the view of showing their influence on the social state. But it is evident that such a vast field of inquiry must exceed the powers of any single writer, and that the attempt to embrace so many difficult and varied subjects under one division of knowledge, tends to confuse rather than to elucidate. Modern writers, especially in England, have therefore limited their inquiries to the principles which govern the production and accumulation of wealth, and its distribution and consumption. "The Wealth of Nations" was the title which Adam Smith gave to his work. In this consists the main difference between the modern English and the Italian and French economists. The latter maintain that the political economist is concerned not only with the aggregate production of wealth, but with its most beneficial distribution among individuals, not only with wealth in short, but with happiness also. The modern English writers, on the contrary, say that the appropriate subject of the political economist is not happiness, but wealth; that wealth is confined to material objects, the produce of land and of industry; that the political economist who assumes to explain the phenomena of the production of wealth ought to lay down the general principles on which wealth is produced, as they are deducible from actual facts; it is the business of the statesman, the philosopher, or the politician, to say what he thinks best for the general prosperity of society, after he has examined the evidence of the political economist, which is an essential part of the evidence, but not the sole evidence to be attended to in the conduct of a nation's affairs. But here the English economists also seem to be divided among themselves. Some appear to think that the principles of political economy, as the term is understood by them, may be deduced with the certainty of mathematical demonstration, whilst others assert that there are many important propositions in political economy which require limitations and exceptions. "The desire to simplify and generalise has occasioned an unwillingness to acknowledge the operation of more causes than one in the production of particular effects; and if one cause would account for a considerable portion of a certain class of phenomena, the whole has been ascribed to it without sufficient attention to the facts which would not admit of being so solved." (Malthus, 'Principles of Political Economy,' Introduction.) Malthus quotes the controversy on the bullion question as an instance of this kind of error.

We cannot enter into anything like an examination, however brief, of the principles of political economy; but shall merely state a few general propositions which are universally acknowledged as true. 1. Every man desires to obtain additional wealth with as little trouble to himself as possible. 2. The increase of population is limited either by physical or moral evil, or by prudential motives. 3. The powers of labour, and of the other instruments which produce wealth, may be indefinitely increased, by using their products as the means of further production. 4. Agricultural produce is not susceptible of the same unlimited increase as manufactures. The principal topics discussed by political economists are: 1, the definition of wealth; 2, of productive and unproductive labour; 3, of the nature and measures of value; 4, of the rent of land; 5, the wages of labour; 6, the profits of capital

7, the results of machinery; 8, the circulating medium, or currency; 9, the nature and conditions of commerce, or exchange of commodities. Most of these subjects are treated in this work under the heads ACCUMULATION, BALANCE OF TRADE, BULLION, CONSUMPTION, CURRENCY, EXCHANGE, PROFIT, RENT, WAGES, WEALTH.

History of the Science.—The great nations of antiquity, the Greeks and Romans, had no notion of what we understand by political economy. They sought to increase their wealth chiefly by war, by conquering and plundering weaker nations, and appropriating to their own use part of the produce of their industry. They considered handicraft and trade as degrading to a citizen, and left those pursuits to be exercised by slaves or freedmen. The Romans, in the earlier ages of the republic, held agriculture in more esteem; but after they had extended their conquests beyond the limits of Latium, the business of agriculture also was mainly conducted by slaves. The consequences of this system are well known; agriculture declined, and the people of Rome were obliged to be fed by corn from the provinces. It is evident that in such a state of society there will be no room for the consideration of some of the most important questions of political economy, which are based upon the principles of free labour and competition. It appears that the Romans considered gold not as the representative of wealth, but as wealth itself, for we find that the senate forbade its exportation. (Cicero, 'Pro Flacco,' 28.)

After the fall of the Roman empire, the free towns that rose in the middle ages, Pisa, Venice, Florence, Genoa, and the Hanseatic towns, were essentially commercial, and with them the "mercantile" system, as it is called, may be said to have originated, at least in practice; for it was not expounded and reduced to rules until centuries after. This system consisted in looking to foreign trade as the source of wealth, selling dear and buying cheap, and thereby realising, by the exchange, a surplus in bullion, which surplus was employed in increasing the quantity of produce to be sold. Shipping, foreign marts, colonies or factories abroad, were the means employed for these objects. But as each mercantile nation sought a monopoly of trade, restrictions were resorted to in order to favour its own commerce and impede or depress that of others. This led to jealousies and wars, which ended with the ruin of one or the other of the contending parties. This system was narrow and exclusive: it considered only one state, and built the prosperity of that state on the depression of others. It was affected by the same error as the military system of conquerors, who wish to exalt and enrich one country by subjugating and plundering another, overlooking the fact that the prosperity of other countries is part of the general prosperity of the world, in which our own country must share. The principle that "the whole world as to trade is but as one nation or people, and therein nations are as persons" (Sir Dudley North's 'Discourses on Trade,' 1661), was not known as yet, and indeed it may be said to be acknowledged, even now, by comparatively few in any country.

Another mistake of the states of the middle ages was that of considering gold and silver as constituting the exclusive wealth of a country; their attention was fixed on money not as a means, but as the end of trade, and as the most beneficial surplus, which they endeavoured to retain in their coffers by enacting severe penalties against its exportation. Hence the earlier Italian writers on commerce treat exclusively of money, its standard, and the evils of tampering with it. Gasparo Scaruffi, of Reggio near Modena, wrote, in 1579, 'Discorso sopra le Monete, e della vera proporzione frà l'oro e l'argento.' In 1588 Bernardo Davanzati of Florence wrote a short treatise, 'Sulle Monete,' and another 'Sui Cambj,' or 'The Exchanges.' Antonio Serra, a native of Cosenza in Calabria, published, in 1613, 'Breve Trattato delle Cause che possono far abbondare i Regni d'Oro e d'Argento.' Looking upon gold and silver as constituting the wealth of a state, Serra investigates the means of making them flow abundantly into a country. Among these means he reckons manufactures, "which afford a much greater return than agriculture;" and maritime commerce. But "these means," adds Serra, "are of no avail without fixed laws, order, and security for persons and property, for there can be no prosperity where there are continual changes of dynasties and laws." This shows that Serra, considering the age and country in which he lived, had formed some correct and extended notions of political economy. His book however remained unnoticed, and the author, being implicated, as it seems, in some conspiracy against the Spanish rulers of Naples, was imprisoned for ten years, and underwent the torture seven times. It is not known when and where he died. Turbolo of Naples wrote several treatises on the coinage and the state of money in the kingdom of Naples; 'Discorsi e Relazione sulle Monete del Regno di Napoli,' 1616, 1618, 1623, and 1629. Geminiano Montanari of Modena published, in 1680, 'Trattato Mercantile delle Monete,' and afterwards, 'Trattato del Valore delle Monete in tutti gli Stati,' in which he lays down sound principles for regulating the coinage.

The first writers on the subject of commerce at large appeared in England. Raleigh wrote, in 1595, his 'Essay on Trade;' Edward Misselden wrote his 'Circle of Trade,' in 1623, and Louis Roberts his 'Treasure of Traffic,' in 1641. Thomas Mun wrote, in 1621, his 'Defence of the East India Trade,' in which he exploded the notion that money exclusively constituted wealth. He compared the exportation of gold and silver wherewith to buy goods for importation, with the seed which the husbandman throws into the earth that he may reap a plentiful harvest; and in his 'Treasure of Foreign Trade,' published in 1664, Mun advocates the same principle. But Sir William Petty went further than any of his predecessors or contemporaries in asserting enlarged views of political economy. In his treatise 'On Taxes and Contributions,' published in 1667, he was the first to state, though in an incidental manner, that "it was the labour required for the production of commodities which determined their value." He also wrote his 'Quantulumcunque,' a treatise on money, in which he condemned the laws regulating the rate of interest, and combated the notion that a country may be drained of cash by an unfavourable balance of trade. [PETTY, SIR WILLIAM, in BIOG. DIV.]

In France, the minister Colbert, a contemporary of Sir William Petty, was a great promoter of the mercantile system in all its exclusiveness [COLBERT in BIOG. DIV.], and the principles of that system continued to prevail in France after his death till the time of Quesnay. Pierre le Pesant, Seigneur de Bois Guibert, published, in 1695, his 'Détail sur la France,' in which he treated both of commerce and money, but the author was banished because some of his propositions reflected upon feudal rights and ecclesiastical privileges. Twelve years later Vauban published his 'Dixme Royale,' in which he proposed a new plan of taxation.

In England, Locke, in his 'Essay on Civil Government' (b. xi., 40-43), argued at length to prove that "labour is the constituent principle of value." There is something to the same purpose in Hobbes's 'Leviathan' (ch. 24). But these were incidental remarks, and not professed investigations on the subject of political economy.

In a tract published in 1677, entitled 'England's Great Happiness,' the notion of the balance of trade is examined and its fallacy exposed. [BALANCE OF TRADE.] Sir Dudley North wrote 'Discourses on Trade,' 1691, which contain more clear and comprehensive notions on trade than had yet been published. Among other propositions, he lays it down as a maxim that "there can be no trade unprofitable to the public; for if any prove so, men soon leave it off, and wherever the traders thrive, the public, of which they are a part, thrive also." It is worthy of notice, by way of contrast, that Montesquieu in the following century wrote a chapter entitled 'To what Nations Commerce is prejudicial.' ('Esprit des Lois,' b. xx., ch. 21.) In 1696 Davenant wrote on 'the Commerce and Revenue of England.' In the next century Sir Matthew Decker wrote an 'Essay on the Causes of the Decline of Foreign Trade,' 1744.

A change of opinion was in the meantime taking place on the Continent with respect to the so-called "mercantile system." François Quesnay, born in 1694, a medical man by profession, and surgeon to Louis XV., being struck by the distressed condition of the French peasantry, endeavoured to draw the attention of the government towards relieving that numerous and ill-used class of people. He proposed the abolition of custom-houses between province and province, the free circulation of corn throughout the kingdom, the suppression of the corvées, and other similar reforms, which were effected after his death by Turgot. Quesnay went further: he assumed as a principle that the earth, or in other words, agriculture, was the only source of wealth, in opposition to Colbert's mercantile system, which fixed that source exclusively in trade. Quesnay allowed that manufactures and merchants were highly useful, but he contended that as they realised no net surplus in the shape of rent, they did not add any greater value to the raw material of the commodities which they manufactured or carried from place to place, than was just equivalent to the value of the capital or stock consumed by them during the time that they were engaged in those operations. He divided society into three classes: 1, a productive class, consisting of farmers and agricultural labourers, who subsist on a portion of the produce of the land, reserved to them as wages of labour and as a reasonable profit on their capital; 2, a proprietary class, namely, those who live on the rent of the land, or the net surplus produce raised by the cultivators, after the necessary expenses have been deducted; 3, an unproductive class, consisting of manufacturers, merchants, servants, and handicraftsmen, "whose labour, though useful, adds nothing to the national wealth, and who subsist entirely on the wages paid to them by the other two classes." (Quesnay, 'Physiocratie, ou Constitution Naturelle des Gouvernemens,' 1768.) As a corollary to these positions, Quesnay and his disciples concluded that all taxes ought to fall upon the land.

Quesnay is considered as the head of the school called the school of the "Economistes," which reckoned amongst its members the Marquis de Mirabeau, father of the celebrated Mirabeau, Mercier de la Rivière, Dupont de Némours, Condorcet, Raynal, Turgot, Necker, and other distinguished men.

Quesnay's principal work on political economy is the 'Physiocratie' already mentioned; but he published other tracts, especially an article 'Sur les Grains,' which was inserted in the 'Encyclopédie,' and in which he advocates the same principles. Though Quesnay considered agriculture as the only source of wealth, he did not advocate any exclusive protection for it, but rather a principle of freedom in all branches of trade. The "Economistes" originated the "Cadastre," which was a survey and valuation of all real property, made by order of the government, for the purpose of assessing the "contribution foncière," or property tax, which they considered as the only legitimate tax. And this principle has prevailed in France and other continental countries, where even now the tax on land and houses forms the main source of the public revenue, being from 20 to 30 per cent. on the rent.

In Italy, Antonio Bandini of Siena had asserted the fundamental principle of the "Economistes," long before Quesnay, in a work which however was not published till 1775. Bandini wrote his 'Discorso Economico' in 1737, with a view of drawing the attention of the Tuscan government to the desolate condition of that vast tract of country called the Maremma of Siena. Bandini advocated freedom of trade in agricultural produce, and recommended the removal of all restrictions upon importation and exportation; he urged the expediency of giving to the cultivators of the soil an interest in the land, by the grant of long leases; and lastly he recommended the removal of the numerous vexatious taxes, and the substitution of a single tax upon land, not excepting ecclesiastical and other privileged property. A MS. copy of Bandini's book was presented to the grand-duke Francis of Lorraine, who however, being soon after elected emperor of Germany, and having removed to Vienna, could not attend to the affairs of the Maremma. But his son Leopold, on coming to the government of Tuscany, consulted Bandini's work, and put into execution the plan therein proposed. The Maremma of Siena assumed a new life, and its population nearly trebled in the course of half a century.

Antonio Broggia of Naples, a merchant by profession, wrote a treatise on taxation, 'Sul Tributi,' in which he admits that there are three sources of wealth, agriculture, handicraft or manufactures, and commerce. He does not consider the tax on land as the only legitimate tax, but proposes three sorts of taxation, land-tax, customs, and gabelle or excise. He says that in a great commercial country the customs and excise, or indirect tax, ought to be preferred, but in an agricultural country like Naples the tax on land must be the principal source of revenue. He condemns taxes on capital and persons, licences and patents, horses and agricultural implements, as detrimental to industry, as well as the government monopolies of salt, tobacco, &c. The author, who belonged to the mercantile school, falls into the error of that school, in wishing to sell as much as possible to foreigners, and buy as little as possible from them.

Ferdinando Galiani also, of Naples, ranks among the most distinguished writers on political economy in the last century. While at Paris, he wrote in French a book on the corn-trade, 'Dialogues sur le Commerce des Blés,' in which he took a middle course between those who advocated an unrestricted trade in corn, and those who wished it to be subject to permanent restrictions. Galiani contends that no universal system can be established on that important subject, and that the laws concerning the trade in corn must vary according to the situation of individual states, the nature and cultivation of their respective soils, and also their political institutions and relations to other countries. Galiani also wrote, in Italian, a work on money, 'Della Moneta,' published in 1750, which is reckoned one of the best on this subject. Taking an enlarged view, he investigated the nature of the value of things, which he said was the result of various circumstances, namely, their scarcity, utility, the quantity and quality of the labour required for their production, and also the time. He extends his investigations to the value of men's abilities, which are to be estimated not only according to their rarity, but also according to the time required for their coming to maturity, and the difficulties encountered before they can attain a station favourable to their development. This is a position analagous to that afterwards stated by Adam Smith (b. i., ch. 10), "that the wages of labour vary with the easiness and cheapness or the difficulty and expense of learning a business." It requires more time and expense to form a physician, or a statesman, or a divine, than a common labourer, and therefore the latter has less value than the former. Galiani combats the received opinion of his time, that high prices were a sign of distress. He also contended that the precious metals were to be considered as merchandise. Galiani may be considered as a reformer of the old mercantile system. [GALIANI, in BIOG. DIV.]

Gian Francesco Pagnini, born at Volterra in 1715, published in 1751 a dissertation 'Sopra il giusto Pregio delle Cose,' or the just value of things, and in 1764 a 'History of the Commerce of Florence,' with a digression on the value of gold and silver, and its proportion to the prices of other things in the 14th and 15th centuries, compared with those in the 18th century. Both works contain sound opinions and interesting facts. Pompeo Neri of Florence wrote, in 1751, 'Osservazioni sopra il Prezzo legale delle Monete,' a work of considerable merit.

Gian Rinaldo Carli, born at Capo d'Istria in 1720, ranks with Galiani as one of the most distinguished Italian political economists. He wrote an elaborate work on coin and currency, and on the mints of Italy: 'Delle Monete e della Istituzione delli Zecche d'Italia,' 3 vols. 4to., 1754-60, in which he completely exhausted the subject. Carli also wrote 'Ragionamento sopra i Bilanci Economici delle Nazioni,' in which he combated the fallacy prevalent in his time about the balance of trade. He also discussed the subject of the corn-trade in a letter addressed to Pompeo Neri, in 1771, 'Sul Libero Commercio dei Grani,' in which he agreed with Galiani in denying the wisdom of a general principle of unrestricted freedom of trade in corn, which he thought ought to be modified according to local circumstances, because he considered the supply of corn as a subject deeply connected with administrative policy, and not a mere commercial question. Carli had a powerful mind, uninfluenced by popular opinions or prevalent systems. Other particulars concerning this distinguished writer are given under CARLI, in BIOG. DIV.

Antonio Genovesi, born in 1712, at Castiglione near Salerno, became professor of the new chair "of commerce and mechanics," founded at Naples in 1755, by Bartolommeo Intiesi, a wealthy Florentine merchant of that city. Genovesi published his lectures under the title of 'Lezioni di Economia Civile,' in 1768. Genovesi took a middle course between the mercantile system and that of the "Economistes." He reckoned three sources of wealth, agriculture, arts, and commerce. He extols agriculture as an ample and perennial spring of public wealth, but he also appreciates commerce and manufactures as the causes of an increase of production. With regard to commerce, he adopts the restrictive system of the mercantile school as to foreign goods, whilst he agrees with the "Economistes" as to the freedom of trade in corn, and of internal trade in general, as well as with respect to the interest of money. He inculcates the principle that labour constitutes the capital of nations as well as of families. But he did not fall into the vulgar error of considering whole classes of society as unproductive because they are not employed in manual labour, such as men of science, scholars, lawyers, soldiers, magistrates, and others. Genovesi wrote also other treatises on political economy, which he succeeded in rendering popular in his own country.

The other Italian political economists of the 18th century are: 1. Francesco Algarotti of Venice, born in 1712, who wrote 'Saggio sul Commercio,' in which he extols commerce as the source of wealth and power, and he quotes the example of England. He also wrote a few short suggestions on the advantages which might be derived from Africa, in a commercial point of view, by the nations of Europe: 'Sulla Preferenza dell' Africa in confronto dell' Asia e dell' America, rapporto all' Industria e dal Commercio degli Europei.' 2. Antonio Zanon of Udine in the Venetian territory, born in 1696, a merchant by profession, wrote letters on agriculture, commerce, and manufactures, which he encouraged also by his exertions. He was a man of a liberal mind and a true philanthropist. 3. Cesare Beccaria of Milan wrote lectures on political economy, in which he expounded, among other things, the advantages of the division of labour, and he investigated the relations of wages and labour, and the nature of productive capitals. With regard to the corn-trade, he agreed with Carli and Galiani in not advising any general system. He considered large masses of property as more advantageous to a country than small subdivisions. In general, Beccaria may be considered as belonging to the school of the "Economistes." [BECCARIA, CESARE BONESANA, in BIOG. DIV.] 4. Pietro Verri, born at Milan in 1727, the intimate friend of Beccaria, although he differed from him on several points of political economy, wrote 'Memorie sull' Economia Pubblica dello Stato di Milano,' in which he shows the decline of that country during the two centuries of Spanish dominion, and ascribes it to the ignorance of its rulers and the absurdity of the laws. He wrote also 'Riflessioni sulle Leggi Vincolanti, principalmente sul Commercio dei Grani,' in which he advocated the principle of absolute liberty. Lastly, he wrote 'Meditazioni sull' Economia Politica,' which were published in 1771, and have been translated into several languages. It is an elementary but useful book. 5. Ferdinando Paoletti, born in 1717, near Florence, wrote, in 1769, 'Pensieri sopra l'Agricoltura,' and, in 1772, 'Veri Mezzi di rendere felici le Societa,' in which he advocated freedom of trade. 6. Gian Battista Vasco, born at Mondovi in Piedmont, in 1733, wrote 'Saggio Politico sulla Moneta,' 1772, in which he treats of various questions of political economy. He afterwards wrote, in French, 'Mémoire sur les Causes de la Mendicité et sur les Moyens de la supprimer,' which he sent to the Academy of Valence in Dauphiné, in 1788. His other works were 'Sulla Felicita Publica considerata nei Coltivatori di Terre proprie;' and 'L'Usura libera.' 7. Giammaria Ortes, born at Venice in 1713, wrote a work entitled 'Dell' Economia Nazionale,' libri sei, 1774, which however remained unknown except to a few friends of the author, until Custodi inserted it in his great collection of the Italian economists. His views were original, and he belonged to none of the schools already established. He lays it down as a fundamental principle that the capital of a nation is always in proportion to the population, and that the only difference is in its distribution. If a portion of the population becomes richer, it can only be by impoverishing the rest. As a consequence of this principle, he asserts that all endeavours to increase industry with a view to increase the national wealth are futile. But he supports also the principle of freedom of trade between nations, because, he says, every nation has its own capital, which cannot be diminished nor increased by exchange. Ortes wrote also 'Riflessioni sulla Popolazione per rapporto all' Economia Nazionale,' 1790, in which he stated several positions which have been since developed by Malthus, such as that population increases in proportion to the increase of production; that population does not always increase with the increase of marriages, &c. 8. Filippo Briganti, a native of Naples, published, in 1780, 'Esame Economico del Sistema Civile,' in which he refutes the theories of Mably, Rousseau, and Linguet, who asserted that the state of society, and civilisation, commerce, and wealth, were the origin of all the evils with which man is afflicted. 9. Gaetano Filangieri, born at Naples in 1752, is known by his work on legislation, the second volume of which treats of political economy. He belonged to the school of the French economists, but he was not a servile follower of that school. He was a supporter of the freedom of trade; he had no prejudices against luxury, but he advocated direct taxation, or the tax on land, and he maintained that large cities were injurious to the prosperity of a country. [Filangieri, in Biog. Div.] 10. The Marquis Caraccioli, while he was viceroy of Sicily, wrote 'Riflessioni sull' Economia e l'Estrazione dei Frumenti della Sicilia fatte ad occasione della Carestia del 1784 ed 1785.' The author, being struck with the fact that Sicily, once the granary of Rome, should be so frequently afflicted with scarcity and famine, sought to investigate the causes of this great change. He recommended freedom of internal trade, but with regard to the exportation of corn, he thought it might be suspended at times by an act of government from prudential motives. 11. Saverio Scrofani, on the contrary, in a 'Memoria sulla Libertà del Commercio dei Grani della Sicilia,' published in 1795, advocated an entire and permanent freedom in the corn-trade, quoting the example of Tuscany, where that system had been in practice since 1767, and had been attended with the best results. 12. Maurizio Solera, a native of Piedmont, wrote in French, 'Essai sur les Valeurs,' which he presented in 1786 to King Victor. He proposed an agricultural bank in order to make up for the scarcity of bullion. But his project was not carried into effect. 13. Lodovico Ricci, a native of Modena, was named, by the Duke Ercole III., member of a commission appointed to inquire into the charitable institutions of the town of Modena. Ricci was the reporter of the commission, and his report was published and dedicated to the duke: 'Riforma degl' Instituti Pii della Città di Modena,' 1787. He was one of the first in Italy (Ortes and Genovesi had already expressed opinions similar to his) who censured indiscriminate charity as encouraging idleness and improvidence, and thus creating pauperism. Italy abounded at that time, more perhaps than any country in Europe, with charitable institutions. In Modena, which had in the time of Ricci a population of 40,000 inhabitants, there were 7000 destitute persons. Ricci demonstrated from historical facts that pauperism increases in proportion to the facility of obtaining relief. He censured legacies for portioning poor girls, and other premiums on marriage, and said that the increase of population should only be the result of labour and frugality, by which the means of subsistence are increased. He proposed that charitable institutions should be supported by private charity, and not by the government, which should not do more than establish workhouses to give employment to paupers and vagrants, instruct the poor classes, and endeavour to raise their moral condition. The advice of Ricci was acted upon by the government of Modena. 14. Giuseppe Palmieri, born in 1721, in the province of Lecce, in the kingdom of Naples, filled several offices in the administration of his country, and wrote observations on the tarif and on national wealth: 'Osservazioni sulle Tariffe con applicazione al Regno di Napoli,' and 'Sulla Ricchezza Nazionale.' In speaking of commerce, he says that a full and universal liberty would be the best system, but as this liberty is not admitted by any nation, the nation that should alone put it in practice might find it turn to its disadvantage, and its condition would be that of a lamb among wolves. He therefore advises not the prohibitive but the restrictive system, or in other words, a system of custom-house duties on the principle of reciprocity. 15. Count Mengotti of Feltra, in the Venetian state, wrote, in 1791, a book against the exclusive mercantile system, which he styled 'Il Colbertismo,' from the name of Colbert, the great patroniser of that system. This work was written in reply to a query proposed by the Economical Society of Florence, which was put in the following words: "Whether in a state which, by its locality and the nature of its soil, is susceptible of increase of produce and population, it be most advisable to favour manufactures by certain restrictions on the exportation of the raw materials, or to leave it an entire freedom?" Mengotti recommended perfect freedom of trade, and his book obtained the prize. It is one of the best written works of the Italian political economists. Mengotti, Beccaria, and Galiani are three writers who, by their style, have succeeded in enlivening an abstruse subject and making their dissertations entertaining as well as instructive. Mengotti wrote also a memoir, 'Sul Commercio dei Romani,' which obtained, in 1787, the prize from the Academy of Inscriptions and Belles Lettres of Paris. Mengotti maintained, that until the first Punic war the Romans had no commerce in an extended sense; that from the first Punic war to the battle of Actium their commerce consisted in carrying home the spoils of other nations; that from Augustus to Constantine their trade was mainly passive and ruinous; they produced nothing, and bought foreign luxuries and even the necessaries of life with the money they extorted from the subject provinces, and at last they fell gradually again into poverty and barbarism.

The above are the principal Italian political economists of the 18th century. The complete collection of all the Italian writers on political economy was edited by Custodi, in 50 volumes 8vo. Melzi, the vice-president of the Italian republic, supplied the author with the necessary funds for the undertaking. Custodi was afterwards made by Napoleon counsellor of state of the kingdom of Italy, baron, knight of the iron crown, and secretary of finance.

In England, the science of political economy made a marked progress in the latter part of the 18th century through the exertions of Adam Smith, who is considered as the founder of the modern school. In 1776 Smith published his great work, with the modest title of 'An Enquiry into the Nature and Causes of the Wealth of Nations.' In the first book he treats of the division of labour and its wonderful effects, of the real and nominal price of commodities, the wages of labour, the profits of stock, and the rent of land. Book ii. treats of the nature, accumulation, and employment of stock or capital. Book iii. is in a great measure historical, and treats of the different progress of opulence in different nations. Book iv. is employed in discussing the various systems of political economy. Smith did not follow implicitly either the mercantile system or that of the economists; he showed, in opposition to the latter, that the labour of manufacturers and merchants is productive and is a source of wealth; but he at the same time considered agriculture as the most productive kind of labour, and the home trade as more productive than foreign trade. These positions have been combated by writers who have adopted many of his general views. On the subject of foreign trade, modern writers on political economy are divided, some maintaining that all foreign trade is advantageous to a country precisely in the degree in which it is profitable to those who are engaged in it, and independently of war and peace and other national vicissitudes; whilst others contend that the immediate interest of the trader is not in all cases a criterion of the permanent national interest.

Adam Smith's doctrine of universal free trade has found many opponents, and is in fact still a theory, for it is not in practice in any country, though in our own a much nearer approximation to it is made than in any other. His definition of productive and unproductive labour has been contradicted by Malthus, in his 'Principles of Political Economy,' and in France by Say and others. Smith considered commerce as an exchange between producers of various commodities, but not as a cause of fresh production by stimulating new wants in the producers. His doctrine of the "natural rate of wages" has also been controverted. (McCulloch's "edition" of Smith's 'Wealth of Nations,' with a 'Biography of the Author, and Notes and Supplementary Dissertations,' by the editor.)

In 1798 Malthus published his 'Essay on the Principle of Population,' in which he demonstrated that "an increase in the means of subsistence is the only sure criterion of a real permanent and beneficial increase in the numbers of any people." He stated that the population never falls below the level of subsistence, but that it tends, on the contrary, always to exceed it, and is only kept down by moral or physical checks. A consequence of these positions is, that any artificial stimulus to the increase of population by premiums on marriage, laws against celibacy, &c., is injudicious. These inferences had been anticipated by the Italian political economists Ortes and Ricci.

In France, J. B. Say published, in 1802, 'Traité d'Economie Politique,' in which he expounded the principles of Adam Smith, adding many original and important illustrations, especially on the nature and causes of gluts resulting from over-production, which, he maintained, can only be partial and temporary, and can never occur in every species of commodity at once. Say has written several other works on political economy. Garnier also translated the work of Smith into French.

In 1815 appeared an 'Essay on the Application of Capital to Land,' by Mr. West, Oxford, 1815; and about the same time Malthus published 'An Enquiry into the Nature and Progress of Rent,' a subject which was afterwards investigated and expounded by Mr. Ricardo, in his 'Principles of Political Economy and Taxation,' published in 1817, and which is generally considered as the most important work on political economy since the time of Adam Smith. [Ricardo, in Biog. Div.] The writings of James Mill were also valuable contributions to the literature of the science.

Among other contemporary writers on political economy, may be mentioned, in England, John Stuart Mill, J. R. McCulloch, N. W. Senior, Thomas Tooke, G. R. Porter, Lord Brougham, Archbishop Whately, C. Knight, William Ellis, Col. Torrens, and Lord Overstone. Many of these names will be found in their respective places in the Biog. Div. In France, Sismondi has written several works on political economy: 'De la Richesse des Nations, ou Nouveaux Principes d'Economie Politique;' and 'Etudes sur l'Economie Politique,' which latter work contains many interesting facts, exhibited and commented upon in the usual attractive if not always strictly logical manner of the author. Ganilh published a general review of the principal systems of political economy: 'Des Systêmes d'Economie Politique, et de la Valeur comparative de leurs Doctrines,' 2 vols. 8vo, 1821, a work well deserving a perusal, being written in a temperate spirit and unassuming tone. Frederick Bastiat, also, by numerous works, contributed largely to the popularising of political economy in France; and he has had many successors.

In Germany, Storch published, in French, 'Cours d'Economie Politique,' 6 vols., Petersburg, 1815, and also 'Betrachtungen über die Natur des Nationaleinkommens,' Halle, 1825. Schmalze wrote 'Staatswirthschaftslehre,' 2 vols., Berlin, 1818; and Jakob, 'Grundsätze der Nationalökonomie,' Halle, 1825.

The Spaniards had two writers on political economy towards the end of the last century, Ulloa and Ustariz. The latter wrote 'Teorica y Practica de Comercio y de Marina,' fol., Madrid, 1791.

Political economy has not been neglected in the United States of North America, but few works, we believe, have yet been produced that have attracted much attention in Europe. Tucker's 'Laws of Wages, Profits, and Rent investigated,' and his 'Theory of Money and Banks investigated,' are valuable contributions to the science.

In Italy, the principal writer of the present century on political economy was Melchiorre Gioia of Piacenza, who died in 1824. Gioia was a jurist, a moralist, and a politician, as well as a political economist, and a notice of his works and a short account of his life are given under his name in the Biographical Division. Here, however, we shall dwell at more length upon his great work on political economy, 'Nuovo Prospetto delle Scienze Economische,' 6 vols. 4to, Milan, 1815-17. Gioia quotes most of the writers, Italian and foreign, who had preceded him, and endeavours to condense their various systems and opinions into a series of principles with their legitimate deductions. He lays down the following objects of the science:—1. To diminish the labour and the time employed in the production, as well as to diminish the quantity of the raw elements employed; in short, to produce with as little labour, time, and cost as possible. 2. To increase the quantity, perfection, and durability of the things produced. 3. The means of obtaining the above results consist in power, which is increased by capital, machinery, credit, association, distribution of labour, in knowledge of the means to improve, and will or activity, which is strengthened by liberty, security, and enlightened opinion of the people in general. A great part of the work is in a tabular form, with quotations and original remarks. Speaking of the influence of the government on the production, distribution, and consumption of wealth, Gioia notes a number of cases in which that influence may be useful, and a number of others in which it is injurious. Under the first head he reckons the construction of good roads, the distribution of courts of justice in each district, to save time and expense to suitors; the establishment of public libraries, consisting of useful books, of collections of natural history, and of philosophical instruments, botanical gardens, &c.; the foundation of gratuitous elementary schools in every commune, and of schools of arts and trades in every town; freedom of the press; the sending well-informed travellers into foreign countries to examine and report the discoveries and improvements made in each. Among the cases in which the influence of the government is injurious, Gioia reckons—1, too heavy taxation, which, by gradually diminishing the disposable capital, prevents its being employed in making improvements; 2, the grant of public money to monastic establishments; 3, the unequal distribution of public burdens; 4, the payment of the judges by fees on the causes which they decide, which is still the case in several countries of the Continent, instead of a fixed salary sufficient to place them above temptation; 5, the inculcation or toleration of popular superstition, false miracles, and impostors; 6, the tribunal of the Inquisition and other inquisitorial censorships, index of forbidden books, &c. Gioia is an advocate for large masses of property, large manufactories, and great commercial cities. His exposition of the advantages of large farms over small ones induced the government of Piedmont to repeal the decree by which the rice-grounds belonging to the crown or the communes were to be parcelled out into small holdings. Gioia gives the preference to arts over agriculture, and he is the only one among the Italian political economists who has established the principle of the "association of labour" (as in the case of joint-stock companies) as an important source of wealth, and has descanted upon its advantages. Gioia wrote also his 'Filosofia della Statistica,' which may be considered as an appendage to his work on political economy. [Gioia, in Biog. Div.]

The other Italian writers on political economy in the present century are—1. Ressi, who in 1808 published a work 'Dell' Economia della Specie Umana,' 4 vols. 8vo. 2. Carlo Bosellini of Modena, who published, in 1817, 'Nuovo Esame delle Sorgenti della Privata e Pubblica Ricchezza.' 3. Giuseppe Pecchio, who wrote, 1, 'Saggio Storico sull' Amministrazione Finanziera dell' ex-Regno d' Italia, dal 1802 al 1814,' London, 1826, in which he treated of various subjects connected with political economy; 2, 'L'Anno Mille Ottocento Ventisei dell' Inghilterra,' Lugano, 1827, in which he treats of the commercial crisis which took place in England in 1826, and of its causes, effects, and remedies; 3, 'Storia dell' Economia Pubblica in Italia,' Lugano, 1829, a work to which the writer of this article is mainly indebted for his account of the Italian writers on political economy. At the end of the work, Pecchio draws a parallel between the Italian and the English economists.

Few English writers on political economy would however admit his to be an accurate statement of their opinions and of the objects of the science as they conceive them. They would also contend that the objects of the science as conceived by the Italian economists are too numerous and too vague to allow of any scientific treatment, and that subjects are blended together by the Italian writers which are capable of being separated and of being confined within distinct and definite limits. Such an objection to the system of the Italian economists is well founded; and the objects of the English economists may be completely defended if their views are simply limited to investigating the elements on which depend the actual production, distribution, and accumulation of wealth in any given community at any given time. This is a field of inquiry sufficiently extensive, and when it has been adequately examined, and not before, we can pass from the determination of what is to what ought to be any one of those elements on which national wealth depends. It would seem almost superfluous to observe that in determining what are the elements of the actual production of a nation, all the elements must be ascertained: the whole condition of the people must therefore be ascertained,—that is, the whole political system must be examined, in order to ascertain what it is, and the state of all the several classes of the community must be ascertained; every law that interferes with a man's actions must be examined, and every restraint that is laid on the disposal of his property. But such an inquiry would be infinite, and yet such an inquiry is necessary in order to ascertain what *is*, and it is quite a distinct matter from determining what *should* be. It follows from these remarks, that the English writers have conceived the science in a way much more limited, but better defined, than the Italian, and yet that even the English writers very inadequately investigate any one branch of political economy, even as they conceive it. Still their inquiries on any given branch of the subject may terminate in a result approaching to the truth, and such a result may be capable of a practical application.

POLLARDS are trees which have had their tops repeatedly cut off for the sake of the faggot-wood, which is used for burning and heating bakers' ovens. The appearance of an old pollard may, in particular situations, be thought picturesque, but nothing can be more unsightly in a landscape than rows of pollards bordering every inclosure, as seen in some countries. It is only in the case of a few trees of quick growth, such as willows and poplars, that there is a profit in making pollards of them. Where wood is required for fuel, it is better to plant a good coppice interspersed with timber-trees; and if this be done judiciously on good sound land, the quantity taken from the farm for this purpose will be as profitable as if it had been kept in cultivation. Trees are often planted in soils which are not worth cultivating; and hence the profit from a good coppice is usually underrated; but if the damage done to the land by the roots and shade of trees be taken into the account, it will be found that it is more profitable to have the wood growing by itself.

On the margin of low rivers running through marshy grounds, it may be profitable to plant willows, poplars, and other soft-wooded and rapidly-growing trees, in order to lop them at stated intervals. Their timber would be of little value if they were left in their natural state; but being lopped every seventh year, they produce rods and faggots, which are readily disposed of. Hence the common saying that "a willow will buy a horse before an oak will buy the saddle."

To manage pollards advantageously the head of the tree should be cut off at a moderate height while the tree is young, and the shoots which spring from the crown must be frequently cut off before they begin to branch out. Thus a good head is formed, throwing out many shoots, which may then be left to grow till they are of a useful size. The willow takes root so readily, that if a branch twelve or fourteen feet long is put two feet into the ground, it will grow, and form a tree at once, which after a few loppings will become a pollard.

If the appearance of rows of pollards is unsightly, the cutting the side branches of trees in hedgerows, leaving only a little tuft at the top, is much worse. No branch above ten feet from the ground should ever be permitted to be cut by a tenant, nor the top of any tree to be cut off in order to make a pollard of it, and a clause to that effect, with a severe penalty, should be inserted in every lease.

POLLUX. [Gemini.]

POLYA'NTHES TUBERO'SA, or the Tuberose (a corruption of *Plante Tubéreuse*), is a tuberous-rooted plant highly prized for the delicious fragrance of its flowers, on which account it is cultivated in the warmer parts of both the old and new world. It is stated to be an Indian plant introduced into England in 1620; it had however been cultivated in Europe a century earlier. It is more probably of South American origin; as a wild tuberose, Polyanthes gracilis, has been found in South Brazil, which is probably the origin of the garden plant.

The tuberose is too tender a plant to be cultivated in England in the open air; but in the south of Europe it finds a climate suitable to it; and the Genoese supply the principal part of the European market with tubers for forcing. The latter are imported into this country by the Italian oilmen, who sell them, with orange-trees, Narcissus roots, and similar products of the south.

In selecting tuberoses for planting, the largest tubers should be preferred, as the smaller ones will often not flower. All offsets should be carefully picked off, so as to concentrate the vegetation in a single eye. They should be planted in March or April, in pots, in a sandy loam, and forced in a hotbed, with as much bottom heat as is given to a melon. The eye should be about an inch below the surface of the soil. Very little water should be given till the plants are growing; but when once in a state of vigour, they may be supplied copiously. An abundance of light and air should be given the plants as soon as they begin to grow, and this should be sedulously attended to as long as they remain in the hotbed; it will however soon be necessary, on account of their height, to remove them to the greenhouse, where they must be placed near the glass, and their roots still exposed to a temperature similar to that from which they were taken. As soon as they show their flowers, but not sooner, they may be removed to the sitting-room, when their flowering will be completed.

POLYANTHUS, a garden variety of the oxlip primrose, with brown flowers, is one of those plants which have from time immemorial been favourites in gardens. It was probably obtained by accident, and is now propagated either by seeds or division of its root. Florists require that a good variety of this flower should possess a strong scape, a well-filled truss, a corolla with a short tube, a bright yellow eye, and a deep rich brown crimson limb, bordered with a well-defined yellow edging. They require less careful cultivation than the auricula with which they are nearly allied [AURICULA], and principally need shade and a strong rich soil kept somewhat moist. Their beauty however diminishes with their age, so that a renewal of the variety from seed is requisite every few years.

POLYCHROITE. [SAFRANIN.]

POLYCHROMATIC ACID. Synonymous with ALOETIC ACID.

POLYCHROME. [ESCULIN.]

POLYCHROMY, a modern term (from the Greek *πολὺς* and *χρῶμα*) used to express the ancient practice of colouring statues and the exteriors of buildings.

Among the earliest civilised nations it was a universal custom to decorate not only their temples and palaces with colours, but the statues with which they were adorned. The Egyptians appear to have covered almost every part of their buildings, and the sculpture on the walls, with brilliant colours and gilding. [EGYPTIAN ARCHITECTURE.] Upon the relics of Assyrian architecture, and the carved slabs, which have been discovered in such large numbers at Kouyunjik, at Nimroud, and especially those of Khorsabad, traces of colour and gilding were in many instances distinctly visible when first found; and we have evidence in the Scriptures (Ezek. xxiii. 14; Jeremiah xxii. 14; Zephaniah ii. 14, &c.), that the walls and ceilings were adorned with figures portrayed in vermilion and other bright colours. [NINEVEH, ARCHITECTURE OF.] So again, the Babylonians, the successors of the ancient Assyrians, whilst imitating the sculpture and architecture of their predecessors, were equally profuse in the application of polychromatic decoration. [PERSIAN ARCHITECTURE.]

It is, however, the polychromy of the ancient Greeks that has most engaged the attention of artists and archæologists. The sources of information respecting it are the remains of Greek art, and the writings of classic authors. There is scarcely any distinct notice of the system or practice of colouring Architecture in any of the ancient writers. A few remarks occur in Vitruvius and Pausanias, which may be construed into an allusion to it, but they are vague, and the systems which have been laid down by several modern writers rest chiefly upon conjecture. It is more than probable, where the architectural members were subject to so great a variety of forms and proportions, that the decorations in colour, which admit of endless variety, were quite arbitrary. Remains of colour have been found by travellers upon ornamental work in most of the architectural ruins of Greece. Many traces were discovered by Dodwell, Stuart, Chandler, Bröndsted, Semper, and others, upon the principal Athenian monuments: upon the temple of Theseus, the Parthenon, the Propylæa, the Erechtheium, the temple on the Ilissus, the monument of Lysicrates, the outer propylæa of the temple of Ceres at Eleusis, and the greater temple at Rhamnus; also upon the temple of Apollo at Bassæ in Arcadia, the Doric ruins at Corinth, the temple of Athene in Ægina, and by Newton upon the remains of the great mausoleum at Halicarnassus; upon the temples of Selinus in Sicily, and upon the basilica at Pæstum.

As to the extent to which the colouring of the exterior of buildings was carried by the Greeks there is considerable difference of opinion. Some excellent authorities, both English and continental, hold that their buildings were entirely covered with colour; while the majority believe that the balance of evidence indicates that in marble buildings the colouring was confined to the capitals of columns, the mouldings and other ornaments, the friezes, the metopes, and the tympana of the pediments. The exterior of the wall of the cella of the temple of Ægina, and the columns of the Doric temple at Corinth (which, however, were not of marble), they admit were covered with a stucco and coloured red. There is, however, direct evidence that the Greeks carried their colouring much farther, even in marble buildings. Several travellers have found colour on portions of the Theseum which are not merely ornamental. In like manner it appears from the analysis by Mr. Faraday of stucco brought by Mr. Donaldson from Athens, that "the surface of the shafts of the columns of the Theseum and other parts of the edifices from which these coatings were taken were covered with a coloured coating." (Report of Committee of the Royal Institute of British Architects, appointed in 1836 to investigate the evidence bearing on the employment by the Greeks of Colour in Architecture and Sculpture, published in the 'Transactions' of the Institute, vol. i., 1842.) Wax seems to have been present in most, if not all, of the specimens analysed by Mr. Faraday. Mr. Bracebridge, as is stated in the same Report, found in the northern portico of the Erechtheium, which is sheltered from the sea-breeze, clear remains of "colour of various shades" in the upper part of the fluted columns as well as in the capitals. Also in excavating, in 1835–36, at the south-east angle of the Parthenon, according to the same authority, the workmen came, at a depth of 25 feet, upon a place where, as he conjectures, the workmen of the Parthenon threw their refuse materials, and there "were found many pieces of marble, and among these fragments of triglyphs, of fluted columns, and of statues, particularly a female head. These three last-mentioned fragments were painted with the brightest red, blue, and yellow, or rather vermilion, ultra-marine, and straw-colour, which last may have faded in the earth." Mr. Penrose found traces of colour of a peculiar yellow tinge upon some parts of the columns of the Parthenon, especially on those of the west front, but he thinks it was originally most likely only a delicate tint to reduce the high light of the marble. Professor Semper and others have also found traces of colour on the constructive as well as the decorative features of Grecian monuments. The latest testimony is that of Mr. Newton, who found in excavating the ruins of the mausoleum of Halicarnassus "an immense number of pieces of painted stucco from the sides of walls," with, among other things, painted borders of the well-known Greek ante-fixal flowers, in several colours; the colours, from the nature of the soil, being preserved in unusual freshness. ('Parliamentary Papers respecting excavations at Budrum,' 1858, p. 4, and Mr. Newton's Letter in Falkener's 'Dædalus,' 1860.)

In later times amongst the Romans, in the times of Vitruvius and Pliny, the practice seems to have degenerated into a mere taste for gaudy colours, and to have been very general, as we see in the ruins of Pompeii, where, however, occasionally the arabesque decorations upon the walls of the courts in the larger houses are very elegant.

With regard to the system of decorating the mouldings, it appears, from the traces found upon ancient monuments, that they were painted in various ways and in a great variety of colours, whether carved or plain; and a tasteful combination of colours must have greatly heightened the effect of even the richest mouldings. These decorations were not confined to the mouldings of the entablature; the ovolo, echinus, and abacus of the capital, and the toruses of the base, were also coloured. Foliage, ova, and beads were the ordinary decorations; but on the Doric tænia a fret was generally painted, and the cymatia of the pediment-cornices were frequently ornamented with gilded metal-work: the acroteria were also surmounted with gilded figures. Upon the larger mouldings, on which foliage was painted, the outlines of the leaves were engraved in the stone. The mutules, dentils, modillions, and the soffits were also variously coloured; but the Doric guttæ were apparently generally gilded. The faciæ of the architraves, and the coronæ of the cornices, were, at least sometimes, left plain. The Doric architrave was sometimes ornamented with gilded shields, as in the Parthenon at Athens, which were placed immediately beneath the metopes. It appears that all friezes which were decorated with sculpture were coloured, which, if the sculpture itself were uncoloured, would be necessary to give the sculpture a proper relief; for the same reason, the tympana of the pediments would also require colour. In the Doric order, the tympanum would necessarily be of the same colour as the metopes: in the Parthenon they were of a pale blue; and in some of the Sicilian monuments red has been found. The metopes require colour, with or without sculpture, to throw the weight of the pediment upon the triglyphs, its natural supporters, which being left plain united the cornice with the architrave, and gave the whole building an elegant lightness of effect which it otherwise could not have. Sometimes the surfaces of walls, &c., seem to have been ornamented with a diaper or pattern delicately painted.

Polychrome sculpture was quite as general amongst the Greeks as polychrome architecture; it is frequently alluded to by almost all the ancient writers, and many statues of this kind are minutely described by Pausanias. The polylithic and the chryselephantine statues both come under this head. [SCULPTURE.] The painters of statues appear to have constituted a distinct class of artists: *οἱ ἀνδριάντας γράφοντες*, Plato calls them; and Plutarch speaks of the *Ἀγαλμάτων ἐγκανσταί*, "encaustic-painters of statues," and the art itself as *ἀγαλμάτων ἔγκαυσις*.

That the statues were sometimes entirely painted even in the best period of Greek art there can be no doubt, both from the references to the practice in ancient authors and from traces of colour on many existing examples, as in the sculpture of the Theseum, and on such fragments as those found among the waste materials of the Parthenon, mentioned above, and the red colour found by Mr. Newton on the nude parts of some of the statues, and the tawny colour on the hind-quarters of the Lion, found by him at Halicarnassus. That it was not the universal—perhaps not even the common—practice to *paint* the marble entirely, is evident from the conversation between Lycinus and Aristratus, in the dialogue of the 'Portraits,' or 'Panthea,' in Lucian ('De Imag.,' 5–8), from which it is plain that the Venus of Cnidos, by Praxiteles, and other celebrated statues, were not painted, though parts may have been painted, and the whole body covered with an encaustic tint or varnish.

This last process, whatever it was, must however have required great artistic skill and taste. Plato ('De Republ.,' iv. 420) observes, in speaking of statue-painters, "It is not by applying a rich or beautiful colour to any particular part, but by giving every part its local colour, that the whole is made beautiful." And Pliny relates that, Praxitiles being asked which of his marble statues he preferred, answered, "'Those which Nicias has had a hand in;' so much did he attribute to his *circumlitio*." There has been much difference of opinion as to what this circumlitio was. To understand it, we must remember that Nicias was subsequently—for it is pretty clear that it must have been when he was a young man that he painted the statues of Praxiteles [NICIAS, in BIOG. DIV.]—one of the most famous encaustic-painters of Greece; that Plutarch expressly calls the statue-painters encaustic-painters; and that wax is shown by modern chemical analysis to have been a constituent of the pigment employed in colouring the ancient marbles; and we shall then, looking at the word itself, probably conclude that it was the application of some encaustic material, which required to be rubbed in with great dexterity and with still greater refinement. In the circumlitio of Nicias, and of the ἀγαλμάτων ἐγκαυσταί (the encaustic-painters of statues) generally, the naked form probably received only this delicate tint or varnish, the more positive colouring being applied only to the eyes, eye-brows, and lips, to the hair, the draperies, and the various ornaments of dress; and there can be little doubt that marble statues, especially of females, must have had a very beautiful appearance when carefully coloured in this way.

But whatever reserve there may have been in colouring the finer specimens of Grecian sculpture,—and it is almost certain, from the care shown in the selection of the marble, that the colour was not laid on so thickly as to conceal the material,—it is quite certain, from Pausanias and other contemporary authorities, that the archaic statues which were simply objects of worship were entirely coloured, the flesh as well as the drapery, with the strongest—though, as would seem, with conventional rather than the natural—colours, and frequently indeed clothed as well as coloured. Statues of a higher class as works of art often had the hair gilded, and the ears pierced for pendants, as in the case of the Venus de' Medici; and in many statues glass eyes were inserted, with eyelashes of copper, examples of which are still extant.

So direct and various has been the evidence brought to bear on the question of Greek polychromy, that the fact must be regarded as proved; the extent to which it was carried is however less certain; while the desirableness of reviving the practice may be considered more than doubtful. That attempts, more or less partial, have been made to revive the practice by artists of various countries, it is scarcely necessary to mention. One of the most successful attempts is probably that of Mr. Gibson [GIBSON, JOHN, in BIOG. DIV.]; but the admiration which his Venus has obtained, does not appear to have led many other English sculptors to follow his example.

The architects and sculptors of the middle ages painted their buildings and monuments throughout, and with the strongest and brightest colours; but their system was rude and inartistic, being indeed rather ecclesiastical than æsthetic in purpose. In some recent Gothic buildings, and restorations of ancient ones, both in this country and on the Continent, elaborate and costly, if not altogether satisfactory, efforts have been made to revive mediæval polychromy.

POLYGALA SENEGA, *Medical Properties of.* The rootstock and rootlets of this plant, collected in the southern parts of the United States, are used. The rootlets are most potent. The efficacy is greatly impaired by age, so a fresh supply should be procured every year. Neglect of this point is a frequent source of disappointment in using it. Decoction is an objectionable form, infusion in *cold* water is best.

Senega is a powerful agent in combating the secondary effects of antimonial and other metallic poisoning, such as lead. The bark is of a dirty yellow colour; the odour disagreeable; the taste, at first, mucilaginous, then sweet, then acid, but at last acrid, causing an unpleasant feeling of permanent irritation in the throat. The powder of the root causes sneezing: it contains two sorts of resin, a very bitter principle (polygalin), and the acrid principle (senegin, which, when isolated, is insoluble in water, but perfectly so when in its natural state of combination with the extractive matter of the root), isolusin, and polygalate of iron and potassa, &c. It possesses very manifest stimulating and tonic powers, especially over all secreting organs, whether the skin, mucous membranes, or glands. By its irritating qualities it can act as an emetic, but it is rarely used except in croup. In some forms of indigestion, attended with inadequate secretion of saliva, it is extremely useful, but it is permanently serviceable in the chronic ophthalmia of strumous children, as it promotes increased action of the glands. As a gargle, it is an efficacious remedy against the hoarseness occasioned by common colds.

POLYGALIC ACID. This acid is said to constitute the acrid principle of the bitter milkwort. It is a white amorphous powder, without odour, and of a very irritating acrid taste. It is very slightly soluble in cold water, but tolerably so in hot. Polygalic acid is very imperfectly known, and may be identical with saponic acid. It is composed of:—

Carbon	55·70
Hydrogen	7·53
Oxygen	36·77
	100·00

POLY'GAMY is the name of the custom according to which a man may have more than one lawful wife at a time, which custom prevails in several countries. Polygamy has existed in Asia from time immemorial, under the old religions, and Mohammedanism adopted and confirmed the custom. Montesquieu pretends that polygamy in the East is the consequence of the greater number of female births in that country; but this surmise is by no means proved. Another and a more plausible reason may be found in the premature old age of the female sex in some countries. Niebuhr, in his 'Travels in Arabia,' gives a curious conversation which he had with an Arab on the subject.

The Romans did not practise polygamy, nor did the Greeks. The barbarous nations, on the contrary, that is to say, those who were not Greeks or Romans, practised polygamy, with the exception of the Germans, "who alone," says Tacitus, "among all the barbarians, are content with a single wife." ('German.,' 17.)

In the Scriptures we find instances of polygamy recorded before the flood. (Genesis iv. 19.) It was common in the patriarchal times, and we have the instance of Jacob marrying two sisters. By the law of Moses it appears to have been tolerated. (Exodus xxi. 9, 10, and Deuteronomy xxi. 15.) But in the time of our Saviour, no indication appears of its being common among the Jews. Repudiation, or divorce, however, was frequent, and our Saviour (Matthew xix. 9) reprobates the custom. St. Paul speaks always of marriage in terms implying the union of one man with one woman. In Christian countries, Polygamy has been long since universally forbidden, both by the church and by the civil law, under severe penalties, which in some countries amounted to death. In England, it is an offence punishable with transportation, or imprisonment for two years, for a married man or married woman to marry another person during the lifetime of the first wife or husband.

The Koran allows a man to have four legitimate wives; but it is only the rich who avail themselves of this permission. The Arabs are generally content with one wife.

Polygamy is different from modern concubinage, which is the cohabitation of man and woman unsanctioned by any legal ceremony or legal form.

PO'LYGLOTTS (πολύγλωττα, from πολὺς, much, many, and γλῶττα, a tongue), books in several languages. The application of the word is restricted to the Bible, which being a collection of books written by various persons, at various times, and on various subjects, is called Biblia (books), and a Polyglott Bible is therefore called Biblia Polyglotta.

The idea of a Polyglott Bible seems to have been first conceived in the 3rd century, by Origen, who spent many years of immense labour in forming the Old Testament into such a work. This is commonly called Biblia Hexapla, the Bible in six columns. The six columns consisted of 1, the Hebrew text; 2, the Hebrew in Greek characters; 3, the Greek version of Aquila; 4, the Greek version of Symmachus; 5, the Septuagint; 6, the Greek version of Theodotion. These six columns went through the work; but some portions were in eight columns and others in nine, and with reference to these portions it is called Octapla and Enneapla. Considered apart from the Hebrew, and the Hebrew in Greek characters, it is called Tetrapla, the Bible in four columns. Though two languages only were used in the formation of this work, it might not improperly be called a Polyglott. It is to be lamented that, except in the Septuagint, only a few fragments of Origen's performance have come down to us. These were published by Montfaucon, in two vols. folio, Paris, 1714, under the title 'Hexaplorum Originis quae supersunt.'

Among the moderns, Aldus Manutius first planned a Polyglott in Hebrew, Greek, and Latin; but he never printed more than one sheet, a copy of which, supposed to be the only one in existence, is in the royal library at Paris. Its date is 1501. Since that time various Polyglotts have been published, of which the principal are the following:—

I. The Complutensian Polyglott. This was printed at Complutum, the Latin name of Alcala de Henares in Spain. It was begun in 1502, and finished in 1517, but it was not published before 1522. It was patronised by Cardinal Francis Ximenes [CISNEROS, in BIOG. DIV.], who employed seven learned men competent for the undertaking, and who munificently defrayed the entire expenses of its publication. This noble work was dedicated by its patron to Pope Leo X. It is in six volumes, folio. In the Old Testament each page consists of three columns, the left-hand page presenting the Hebrew, the Vulgate, and the Septuagint, and the right hand the Septuagint, the Vulgate, and the Hebrew, with Hebrew primitives in the outer margin, and a supralineary Latin interpretation of the Septuagint. At the lower part of the page is a Chaldee paraphrase with a Latin interpretation, in two columns. In the New Testament each page has two columns, consisting of the Greek text and the Latin Vulgate with marginal references. The Greek Testament of this Polyglott is remarkable as being the first complete edition ever printed. Besides a variety of prefatory matter in the first volume, the whole of the sixth volume, with the concluding part of the fifth, consists of several distinct performances, making a large apparatus of elementary biblical literature. Of the Complutensian Polyglott 600 copies only were printed, and one is seldom met with except occasionally in public libraries.

II. The Antwerp Polyglott. This was printed by Christopher Plantin, at Antwerp, 1569-1572, in eight vols. folio. The editor was Arias Montanus, who had about sixty assistants. The work was published under the sanction of Philip II., king of Spain, who is reported to have defrayed its expenses, though some are of opinion that he merely lent the money to Plantin, and demanded its repayment in such a manner as to involve him in very great distress. The whole of the Complutensian Polyglott is comprised in this of Antwerp, besides another Chaldee paraphrase of a part of the Old Testament, a Syriac version of the New Testament, and the Latin translation of Santes Pagninus, altered by the editor, Arias Montanus. The Old Testament is in four columns, two in each page, a Latin interpretation of the Septuagint forming one of the columns, with a Chaldee paraphrase on the lower part of the left-hand page, and a Latin interpretation on that of the right. In the New Testament the versions are similarly arranged, Syriac being in place of the Hebrew, and the Latin of Pagninus answering to the Latin interpretation of the Septuagint. The types are bold and finely formed, and the paper is of a yellowish cast and of excellent quality. The sixth, seventh, and eighth volumes consist of lexicons, grammars, and other aids for understanding the contents of the preceding volumes. Of this Polyglott 500 copies only were printed, and the greater number of these were lost in being conveyed by sea to Spain, so that it is more rare than even its predecessor of Complutum.

III. The Parisian Polyglott. This was printed at Paris, by Antony Vitré, 1628-1645, in 10 vols. large folio. The editor was Guido Michael le Jay, who at this time was a layman, but afterwards became an ecclesiastic. He had several learned associates, and he might have had the patronage of Cardinal Richelieu, but, refusing this favour and venturing to publish the work at his own expense, he brought ruin upon himself. This splendid performance contains all that is in the two preceding Polyglotts, with the addition of an Arabic version of the Old and New Testament, a Syriac version of the former, and the Samaritan Pentateuch. These additions however are made separately, so that, though the Parisian Polyglott contains portions of the Bible in seven languages, its pages do not exhibit at one view more than the Antwerp Polyglott. These ten volumes, in imperial folio, present attractions of no ordinary kind. The paper, though perhaps not so fine as that of the Antwerp Polyglott, is beautiful; the types are large, clear, and elegantly formed; the engraver's art moreover is appropriately displayed in furnishing occasional embellishments; in a word, the Parisian Polyglott is altogether as magnificent a work as can well be conceived.

IV. The London Polyglott. This was edited by the learned Brian Walton, who became afterwards bishop of Chester. It is in six vols., large folio. It was published by subscription, and the volumes came out in the following order:—the first volume in September, 1654; the second in July, 1655; the third in July, 1656; and the last three in 1657. "And thus," says Dr. Twells ('Life of Pocock'), "in about four years was finished the English Polyglott Bible, the glory of that age, and of the English church and nation, a work vastly exceeding all former attempts of that kind, and that came so near perfection as to discourage all future ones." Some portions of this Polyglott are printed in seven languages, all open at one view. No one book is given in nine languages; but nine languages are used in the course of the work, namely, Hebrew, Chaldee, Samaritan, Syriac, Arabic, Persian, Ethiopic, Greek, and Latin. A vast body of introductory matter is in the first volume, and the sixth is made up of various readings, critical remarks, &c. Brian Walton was assisted by a number of men who formed a constellation of oriental and general scholars, such as perhaps have appeared together at no other period during the whole history of our country. One of these men was Dr. Edmund Castell, who published his 'Lexicon Heptaglotton' in 1669, two vols., folio. This is a lexicon of the seven oriental languages occurring in Walton's Polyglott, and it has grammars of all these languages prefixed. It generally accompanies the Polyglott, which can hardly be pronounced complete without it. Walton's work is by no means equal in appearance to the three preceding Polyglotts, but in point of solid usefulness to the biblical scholar it is far beyond any one of them. The eight volumes form an extraordinary collection of aids for studying the original scriptures. As the London Polyglott is frequently found in private libraries, a more minute description of its contents appears to be unnecessary. Its history is recorded at length in Archdeacon Todd's 'Memoirs of the Life and Writings of the Right Rev. Brian Walton, D.D., lord bishop of Chester,' 2 vols. 8vo., London, 1821, a work which comprises also notices of all Walton's coadjutors.

V. Bagster's Polyglott. This work was published by the enterprising bookseller by whose name it is known, in 1 vol. folio, London, 1831. The Old Testament is in eight languages, and the New Testament in nine. Eight languages are exhibited at once upon opening the book. The languages are Hebrew, Greek, English, Latin, German, Italian, French, Spanish, and Syriac, the New Testament being given in the last language as an appendix. To these are added the Samaritan Pentateuch in Hebrew characters; the notes and readings of the Masorites; the chief variations of the Vatican text of the Septuagint (which is followed in this Polyglott), and of the Alexandrian as given by Grabe, Oxford; and of the Greek Testament the whole of the selected various readings given by Griesbach in his own edition of 1805. Prefixed to the work are fifty pages of prolegomena in Latin, by Professor Lee, of Cambridge. The types are small, but clear and elegant, and the paper is of excellent quality. The whole volume presents a very handsome appearance.

On the subject of Polyglott Bibles in general, the reader will be gratified by consulting Horne's 'Introduction;' Butler's 'Horæ Biblicæ;' Clarke's 'Bibliographical Dictionary;' Le Long's 'Bibliotheca Sacra,' improved by Masch. There are many more Polyglotts than these we have mentioned. Among the latest is a 'Biblia Polyglotta,' in four languages—Hebrew, Greek, Latin, and German; it was published during 1850–55, under the editorship of Dr. R. Stier and Dr. Theile. It contains, vol. i., the Pentateuch; vol. ii., the historical books and the Prophets, Daniel excepted; vol. iii., the poetical books, Daniel, and miscellaneous; vol. iv., the New Testament.

PO'LYGON and POLYHEDRON. The word polygon means figure of several angles, and polyhedron means solid of several faces: the first is used for a plane bounded by straight lines, the second for a solid bounded by planes. We shall in this article state the general properties of both kinds of figures, reserving the particular consideration of those which have equal sides or equal faces for the articles REGULAR FIGURES, SOLIDS, &c.

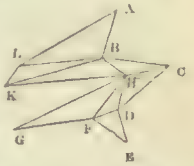
The Elements of Euclid confine themselves to convex polygons, and to a limited number of polyhedrons. The most general propositions with respect to polygons as polygons, that is, which are true whatever the number of sides may be, are as follows: they are either in the Elements or immediately deducible from them.

1. The internal angles of a polygon of n sides are together always equal to $n-2$ pairs of right angles. See ROTATION for the full meaning of this proposition.

2. When a figure of an even number of sides is inscribed in a circle, the sum of the first, third, fifth, &c., angles is equal to the sum of the second, fourth, sixth, &c., angles. But when a figure of an even number of sides is *described about* a circle, for angles read sides in the preceding property.

3. Any one side of a polygon is less than the sum of all the others.

The first-mentioned theorem remains true beyond the limits of Euclid's meaning, namely, so long as the figure of n sides can in any way be divided into $n-2$ triangles: that is, in fact, as long as no side of the figure crosses any other side. Thus the adjoining polygon of 10 sides, being divisible into 8 triangles, has the sum of all its angles equal to 16 right angles, four of these angles being each greater than two right angles.



To make a rule which shall connect the angles of any polygon whatsoever, that is, of any figure, however irregular, in which a point returns by a succession of straight lines to the point from whence it set out, would be difficult in the ordinary way of measuring angles. On this subject see SIGN.

A polygon of n sides or edges has one face, and n angular points or corners: that is, the number of faces and corners together exceed the number of edges by 1. On one side of the polygon let another polygon be described: it is then obvious that the two polygons have two corners in common, but only one edge, or else three corners and two edges, &c.; that is, whatever *new* corners are added, one more new edge is added: or, since one face is added, the number of faces and corners is increased by the same as the number of edges. The same may be proved of every new polygon which has one or more sides in common with any of the old ones: and since at the outset the number of corners and faces exceeds the number of edges by 1, and since every alteration adds the same to both sides of this equation, it remains true throughout. Whence the following theorem: let any number of polygons, in the same plane or not, be so connected that each has one side or more in common with one or more of the others: call each polygon one face; each side, to how many polygons soever it may belong, one edge; and each angular point, no matter how many angles may be collected there, one corner: the number of faces and corners will always exceed the number of edges by one.

Let there be a solid polyhedron, and beginning from one given face, annex the others successively: the preceding theorem will remain true, so long as each face which is added adds one or more new edges. But it is obvious that when the polyhedron is completely finished, with the exception of the last face, the completion of the solid, by counting the last face, adds no new edge and no new corner, these having been completely laid down in former faces. Hence,[*] in every solid polyhedron, the number of faces and corners exceeds the number of edges by *two*.

Again, on a given face of a polyhedron as a base, let a second polyhedron be constructed, and on a given face of that a third, and so on, it being permitted to include several faces from different polyhedrons among the faces of the new one. In the part of each new polyhedron which belongs to the preceding ones, as already shown, the corners and faces exceed the number of edges by one; and the same also in the new portion. But since one new polyhedron is added at every step, it follows that the new faces and corners are the same in number as the new edges and polyhedron. But at the beginning, counting one polyhedron, the faces and corners outnumber the edges and polyhedron by one (since they outnumber the edges by 2); and since both sides of this equation receive the same accession for every new polyhedron, it remains always true: that is, the total number of corners and faces in any system of polyhedrons, each of which has one or more faces in common with others, exceeds the total number of edges and polyhedrons by 1.

---

[*] The present mode of demonstrating this well known theorem was given, for the first time to his knowledge, by the author of this article, in the 'Phil. Mag.'; but he has since found that it is substantially contained (under mathematical symbols which rather conceal its simplicity) in a memoir by M. Cauchy, in the 'Journal de l'Ecole Polytechnique.'

In every face of a polyhedron take any point, which for abbreviation we may call the centre of that face. Join the centre of each face with the centres of the adjoining faces; we have thus a new polyhedron, and the points may be so taken, that those lying in the faces which meet at any corner, shall all be in the same plane. The new polyhedron has obviously as many corners as the old one had faces; and as many faces as the old one has corners: the number of edges being the same in both: and if we call a corner triangular, quadrangular, &c., according as three, four, &c., angles meet there, the new solid has as many triangular, &c., faces, as the old solid has triangular, &c., corners, and *vice versâ.* These polyhedrons may be called conjugate to one another.

Thus there is a triangular tetrahedron (four-faced solid) with four triangular corners: consequently the conjugate solid is another tetrahedron of the same kind. The quadrangular hexahedron (of six four-sided faces) has 8 triangular corners: the conjugate solid has therefore 8 triangular faces, and six quadrangular corners (the triangular octahedron). The pentagonal dodecahedron (having 12 five-sided faces) has 20 triangular corners: the conjugate solid has therefore 20 triangular faces and 12 pentagonal corners (the triangular icosahedron). The solids mentioned in this paragraph are those which may be made of equilateral and equiangular faces. [REGULAR SOLIDS.]

Again, a solid can be formed with 14 quadrangular faces, having 8 triangular corners and 8 quadrangular ones; its conjugate solid has therefore 8 triangular and 8 quadrangular faces, with 14 quadrangular corners; the number of edges in both being 8 + 8 + 14 − 2, or 28.

Let F_3, F_4, F_5, &c., be the number of triangular, quadrangular, pentagonal, &c., faces in a solid, and C_3, C_4, C_5, &c., the number of triangular, quadrangular, pentagonal, &c., corners. Let F, C, E, be the total number of faces, corners, and edges; then we have

$$F = F_3 + F_4 + F_5 + \ldots\ldots \quad (1)$$
$$C = C_3 + C_4 + C_5 + \ldots\ldots \quad (2)$$

Again, since $3F_3 + 4F_4 + \ldots\ldots$ is the total number of sides of all the faces, before they are joined, and since the junction joins each with another, we have half the preceding for the number of edges, or

$$2E = 3F_3 + 4F_4 + 5F_5 + \ldots \quad (3)$$
$$2E = 3C_3 + 4C_4 + 5C_5 + \ldots \quad (4)$$

But $F + C = E + 2$, whence we deduce

$$2C = 4 + F_3 + 2F_4 + 3F_5 + \ldots \quad (5)$$
$$2F = 4 + C_3 + 2C_4 + 3C_5 + \ldots \quad (6)$$

Hence $F_3 + F_5 + \ldots\ldots$ and $C_3 + C_5 + \ldots\ldots$ must be even numbers; for if these be subtracted from the even numbers $2C$ and $2F$, it will be seen that even numbers are left: or the number of odd-sided figures must be even, and also the number of odd-angled corners. Moreover the number of corners must be made up of (1) a couple; (2) half as many as there are odd-sided faces; (3) 1 for every quadrangle and pentagon, 2 for every hexagon and heptagon, 3 for every octagon and nonagon, &c.; and the same will be true if we write faces for corners, and corners for faces.

Since every face has at least three sides, and every corner at least three angles, $2E$ cannot fall short of $3F$, nor of $3C$. Hence, neither $4E - 6F$, nor $4E - 6C$ can be negative, that is, neither of the following can be negative:

$$3C_3 + 2C_4 + C_5 - 12 - C_7 - 2C_8 - 3C_9 - \ldots\ldots \quad (7)$$
$$3F_3 + 2F_4 + F_5 - 12 - F_7 - 2F_8 - 2F_9 - \ldots\ldots \quad (8)$$

Hence it appears that there must be either triangular, quadrangular, or pentagonal faces, and either three-angled, four-angled, or five angled corners. Call these the *essential* faces and corners. Hence the following readily follows:

If the essential faces be all triangles, there must be 4 at least; if all quadrangles, 6 at least: if all pentagons, 12 at least: and the same of the corners. If the non-essential faces be all hexagons, or the non-essential corners six-angled, it would appear* that the minimum number of essential faces and corners need not be increased, how many hexagons soever, or six-angled corners, there may be.

We easily show that the formulæ in (7) and (8) are $2F_4 + 4F_5 + 6F_6 + \ldots$ and $2C_4 + 4C_5 + 6C_6 + \ldots\ldots$ from which, by addition, we find

$$F_3 + C_3 = 8 + F_5 + C_5 + 2(F_6 + C_6) + 3(F_7 + C_7) + \ldots\ldots$$

That is, calling both triangles and three-angled corners by the name of *triplets*, quadrangles and four-angled corners by that of *quadruplets*, &c., we have the following theorem:—Space cannot be inclosed without triplets: and the triplets are in number 8, and one for each quintuplet, and two for each sextuplet, and three for each septuplet, &c.

If all the corners be three-angled, we have $2E = 3C$, or (8) vanishes. If then all the faces be of sides not exceeding six, we have

$$3F_3 + 2F_4 + F_5 = 12.$$

Similarly, if all the faces be triangular, and the corners nowhere more than six-angled, we must have

$$3C_3 + 2C_4 + C_5 = 12.$$

Hence it follows that when all the corners are three-angled, and all the faces either pentagons or hexagons, the number of pentagons can be neither more nor less than 12: also that when all the faces are triangles, and all the corners five-angled or six-angled, the number of five-angled corners can be neither more nor less than 12.

If all the corners be four-angled, we have $2E = 4C$, or

$$F_3 = 8 + F_5 + 2F_6 + \ldots\ldots$$

whence there must be at least 8 triangles. And similarly, if all the sides be quadrangular, there must be at least 8 three-angled corners.

If all the corners be five-angled, we have $2E = 5C$, or

$$F_3 = 20 + 2F_4 + 5F_5 + 8F_6 + \ldots\ldots$$

so that there must be at least 20 triangular faces. Similarly if all the faces be pentagonal, there must be at least 20 three angled corners.

Some of the most obvious ways in which figures may be put together so as to enclose space are as follows:—

1. Two *n*-sided faces, joined by *n* quadrangles. This includes the prism and truncated pyramid, and also every quadrangular hexahedron.

2. The pyramid, with one *n*-sided face and *n* triangles.

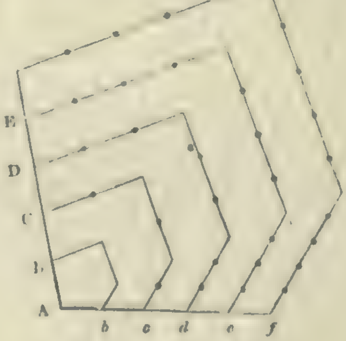
3. The solid with *n* quadrangles, and 2 *n* triangles, the symmetrical case of which is a prism surmounted at each end by a pyramid.

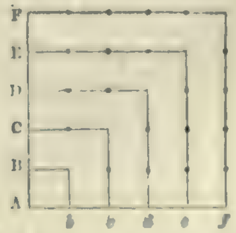
4. Two faces of *n* sides, and *m n* quadrangles, *m* being any whole number.

5. Twelve quadrangles so arranged that four of them are placed corner to corner, the figure being finished by four others on each side. When the quadrangles are all equilateral, this is the common rhombic dodecahedron.

6. The pentagonal dodecahedron, in which there are two pentagons, each of which has another pentagon on every side, the two figures being placed together so that the projecting angles of the one fill up the re-entering angles of the other.

7. The triangular icosahedron, the conjugate solid of the last, which may be thus imagined. Let a pentagonal prism be surmounted at each extremity by a pyramid, and let the sides of the prism which join the angles of the opposite pentagons, and also a diagonal in each quadrangle, be supposed to be formed of extensible and contractible threads. Turn one of the surmounting pyramids partly round: then the sides and diagonals of the five quadrangles will no longer continue in the same plane, but will form ten triangles, which, with the ten belonging to the pyramids, complete the number required.





When the sides of a polygon are given, the polygon itself is not given, unless it be a triangle: thus there is an infinite number of quadrangles which have the same four sides. But it is very remarkable that when a solid is formed of given faces, in a given order of juxtaposition, those faces, if they form a solid at all, can only form one. This is the reason of the stability of solid figures; were it not for this, a box, for example, would require internal cross-pieces to support the sides. This remarkable property is assumed by Euclid as a part of a definition, and that improperly; since it is a new axiom.

---

* Remember however that this subject is very incompletely known; and though some necessary conditions can be laid down, it has never been found out what conditions are both necessary and sufficient in order that a given number of faces may enclose space.

A proof of the axiom implied in the above was given by M. Cauchy in the article already cited, and will be found in the notes to Legendre's Geometry. It is sufficient, but depends on considerations foreign to the subject as usually considered.

For the remarkable division of equal solids into symmetrically and unsymmetrically equal, see SYMMETRICAL: for the more general view of the nature of polygons, suggested by modern geometry, see TRANSVERSAL: see also TRIANGLE, REGULAR FIGURES and REGULAR SOLIDS, TRIGONOMETRY, &c.

To explain the meaning of the term polygonal number [NUMBERS, APPELLATIONS OF], let us take as an instance the pentagonal number. Take any pentagon B A *b*, and construct a set of pentagons, A C *c*, A D *d*, &c., double, treble, &c., of A B *b* in linear dimension. Divide the sides of each pentagon into parts, each equal to the corresponding side of A B *b*. Then if we begin with A, which is one point, and afterwards take in all the points of the first pentagon, we have 1 + 4, or 5 points. If we now add all the additional points of the second pentagon (including subdivision-points), we have 1 + 4 + 7 or 12 points. Take in the next pentagon, and we have 1 + 4 + 7 + 10, or 22 points. Hence the series 1, 5, 12, 22, &c., is called the series of pentagonal numbers; and a set of numbers is thus pointed out which may be as justly called pentagonal as the set 1, 4, 9, &c., may be called square. It must be supposed that the various sets of polygonal numbers were suggested by the square numbers.

POLYGON OF FORCES. A well-known proposition under this name, attributed to Leibnitz. If any number of forces act upon a point, and we take a polygon, one of whose sides is formed by the line representing one of the forces, and the other sides in succession by lines representing the other forces in magnitude, and parallel to their directions, then the line which completes the polygon will represent the resultant of the whole.

POLYGON, REGULAR. [REGULAR FIGURES; REGULAR SOLIDS.]

POLYGONAL NUMBERS. [NUMBERS, APPELLATIONS OF.]

POLYHEDRON. [POLYGON AND POLYHEDRON.]

POLYMERIDES. Chemical compounds which have the same percentage composition, but a different molecular arrangement. Thus, acetate of methyl and formiate of ethyl are polymerides :—

Acetate of methyl . . . . $\left.\begin{matrix} C_2H_3 \\ C_4H_3O_2 \end{matrix}\right\} O_2 = C_6H_6O_4$

Formiate of ethyl . . . . . $\left.\begin{matrix} C_4H_5 \\ C_2H\ O_2 \end{matrix}\right\} O_2 = C_6H_6O_4$

POLYNOMIAL, an algebraical word meaning an expression which has several terms, being the general term under which are included, binomials, trinomials, quadrinomials, &c., or expressions of two, three, four, &c. terms. The *polynomial theorem* means the theorem by which a polynomial expression is raised to its several powers. For an easy way of doing this, see 'Library of Useful Knowledge,' "Diff. Calc.," pp. 328-337.

POLYPUS is a morbid growth attached to the interior of one or other of the mucous canals, by a more or less narrow pedicle. Polypi occur most frequently near the orifices of external communication of the mucous canals, as in the uterus, the fauces, the larynx, and the nose. A description of those that grow in the last of these situations may serve for all.

Polypi of the nose are of four kinds, which are named respectively, vesicular, gelatinous, fibrous, and malignant. Vesicular polypi are gray or yellowish transparent vesicles, containing a clear watery fluid with a little mucus; they are very soft, easily break down when they are pressed, and are liable to considerable increase of size when the evaporation from them is decreased in damp weather. They appear to consist of enlarged mucous follicles. Gelatinous polypi are more solid growths, consisting of dull white masses attached to the mucous membrane of the nose, and themselves covered by a fine but rather tough membrane. They seem composed of an excessive growth of the mucous membrane infiltrated with fluid, and having a few fibres running through its substance. Fibrous polypi are still more solid growths; they consist of a dense fibrous and vascular tissue, which it is often difficult to cut through, and which is sometimes converted into bone. They are usually intimately connected with the deeper parts of the mucous membrane. Malignant polypi are growths of a cancerous nature from the mucous membrane, which have received the name of polypi rather from having the same situation as the preceding than from their similarity of form. They may assume the characters of simple or schirrhous cancer, but more commonly they have those of the soft or medullary variety [CANCER] which is frequently called fungus hæmatodes.

The common symptoms of all polypi of the nose are that the patient is unable to breathe through the nostril in which they are placed, and has a nasal voice; there is usually a discharge of watery mucus, a loss of smell, and a diminution of the power of taste. If situated far back in the nose, they may cause deafness, or obstruct the swallowing of food. They even render the breathing difficult. The softer kinds seldom produce worse effects than these, for their growth is restrained by the firm tissues of the nostrils; but the two last and firm varieties will continue to increase, expanding the bones and other tissues of the nostrils and face into huge and hideous swellings, and producing death either by their ulceration, or by their pressure on the vessels of the brain, or on the brain itself through the base of the skull.

The most usual situation of polypi is in the upper and back parts of the nostrils; and almost always on the outer wall, the septum being very rarely affected. In their increase they mould themselves to the form of the passages of the nose, and at last protrude either forwards through the anterior openings or backwards into the fauces.

The growth of vesicular polypi is usually connected with a generally disordered state of the health. They seldom require to be removed by operation; the patient should take mild alterative and tonic medicines with purgatives; and lotions containing alum or sulphate of zinc, or some equally powerful astringent, should be frequently injected into the nostrils. When the polypi are thus destroyed, ointment containing nitrate of mercury, or savine powder, or some other stimulant, should be rubbed on the membrane where they were seated. Gelatinous polypi are not usually benefited by the preceding plan of treatment; although after their removal it is very useful to prevent them from growing again. They must be pulled from their attachment by forceps, which should have rough blades, and, if possible, be placed around the pedicle of the growth, and withdrawn with a kind of twisting motion. All the polypi being thus removed, the mucous membrane should have some powerfully astringent lotion or ointment applied to it. The fibrous polypi usually require a more difficult operation for their removal; when they can be withdrawn by the forceps, it is only with much difficulty, from their being seated far back in the nostrils, and with some violence and danger of hemorrhage. In some cases a ligature may be tied round the base of such a polypus, so as to make it slough off; in others they must be cut out with the knife or scissors. The choice of these operations must be made according to the circumstances of each case. After their removal, the same means should be adopted to prevent their return as in the preceding cases. The malignant growths in the nose, like those in other parts of the body, where their early and complete removal cannot certainly be accomplished, had better be treated only by palliative measures.

PO'LYTHEISM (πολὺς, much, many, θεὸς, a god), the doctrine or worship of a plurality of gods. This form of the word is not found in Greek writers. Philo-Judæus conveys the notion by τὸ πολύθεον, and πολύθεος δόξα, and Justin Martyr by πολυθεότης. Philo also speaks of polyarchy (πολυαρχία), with which he contrasts monarchy (μοναρχία), meaning respectively polytheism and the unity of God. St. Athanasius uses πολυθεία as the opposite to μοναρχία.

Polytheism differs from idolatry in this respect :—the former refers to a plurality of gods, without including necessarily the notion of *forms*, real or imaginary; the latter refers either to one god only, under some one visible form, or to any number of gods, under as many visible forms.

No one who takes the Bible for his authority will deny that in the earliest ages of mankind the unity of God was implicitly believed. When the idea of a plurality of gods was first entertained, it is impossible to say. The writings of Moses contain no evidence that men were polytheists before the flood; but it is plain that in the time of Moses (B.C. 1500) polytheism prevailed. It is probable that the Chaldæans, of whom Abraham was one, were addicted to polytheism before his time (B.C. 1900); but it is certain that Abraham was not a polytheist. His contemporaries, Melchizedek, king of Salem, and Abimelech, king of the Philistines, both Canaanites, were worshippers of one God, and the God of Abraham himself. The ancient Persians might have been free from polytheism in Abraham's days; but they became, first, Sabians, or worshippers of the host of heaven, and afterwards Magians, or worshippers of fire. As Magians, they held that there are two principles, one the cause of all good, and the other the cause of all evil; the one they represented by darkness, and the other by light; the former, according to Plutarch ('De Isid. et Osir.,' § 46), was called Oromasdes, and the latter Arimanius. [ARIMANES.] Among the ancient Arabians we find Job and his friends, and Jethro, the contemporary of Moses, worshippers of one God; but yet, in the time of Job, the worship of the heavenly bodies was practised, as is plainly indicated in Job xxxi. 26, 27. The Egyptians, in Abraham's days, seem to have had a religion not different from his; but in the time of Moses, polytheism had become established among them; for many provisions of his law refer to this fact, and are intended especially to guard the Israelites from imitating the polytheism and idolatry of Egypt. Cudworth is of opinion (c. 4, § 18) that polytheism originated in Egypt, but such an assertion is incapable of proof. The Greeks and Romans acknowledged one being, under the names of Zeus (Ζεὺς) and Jupiter, as supreme over all other gods; and they believed further, that this one being was under the absolute power of Fate. Yet these inferior beings were worshipped as gods, and the system was essentially polytheistic.

Cudworth has written at great length to show that the ancient philosophers in general, though they seem to have been polytheists, were not really such, and that they worshipped mentally one Supreme Being under different names. But however this might be, the popular notions were not so refined. Wherever the philosophers have appeared to be polytheists, the people have been polytheists in reality; and, as Philo Judæus says ('De Ebrietate'), "Polytheism in the minds of the ignorant is atheism."

Wherever the Christian religion has been established, polytheism and its attendant evils have disappeared; but there still remain vast portions of the world in which polytheism prevails; and the miseries are inconceivably great which millions of the human race are still voluntarily inflicting upon themselves with a view to propitiate the favour of imaginary deities.

(Cudworth's *Intellectual System*; Henry More's *Mystery of Godliness*; Shuckford's *Connection of Sacred and Profane History*.)

POMEGRANATE. Under PUNICA, in the NAT. HIST. DIV., a notice has been given of the medicinal properties attributed to the flowers and the bark of the root of the pomegranate, but they have not been much used in European practice. The inspissated juice of the fruit forms one of the most agreeable constituents of the sherbets of the East; and the abundant and pleasant acid of the fruit renders it not only a favourite when eaten, but is held in high estimation as an ingredient in those refreshing and cooling beverages so much needed in hot climates, and to which the professors of the Moslem faith are confined. It is also used to flavour certain cooked viands, much as lemon-juice is employed in Europe. In this country it can only be reared as an exotic, and with little success even then as regards the fruit.

PO'NTIFEX was the name by which the Romans designated the members of the most illustrious of their great colleges of priests, and is supposed to have been derived from the sacrifices having been performed on a bridge connecting the city on both sides of the Tiber. The pontiffs are said to have been instituted by Numa Pompilius for the purpose of taking care that the laws relating to religion should be observed by individuals as well as by the state. Their original number, according to Livy (x. 6), was four, two for each of the tribes of the Ramnes and Tities. Cicero ('De Rep.' ii. 14) says that their number was five, but he includes the Pontifex Maximus, or chief pontiff.

The minor pontiffs were a college of priests of which scarcely anything is known: Cicero mentions three members of it ('Harusp. Resp.' 6). The name of the minor pontiffs was afterwards transferred to, or perhaps assumed by, the secretaries of the other pontiffs (pontifices majores: Liv. xxii. 57; Capitolin., 'Vit. Macrin.,' 7).

When the great state offices had become accessible to the plebeians, they also obtained the privilege of being represented in the college of pontiffs by members of their own order. This change was brought about in 300 B.C. by the Ogulnian law, by which the original number of pontiffs, through the addition of four plebeians, was increased to eight, or, including the chief pontiff, to nine. (Liv. x. 6, 9.) The chief pontiff, however, continued to be taken from the patricians to the year 254 B.C. (Liv. 'Epit.' xviii.) This number remained the same for more than two centuries, until in 81 B.C. the dictator Sulla raised it to fifteen. (Liv. 'Epit.' 89.) J. Cæsar added one more pontiff. (Dion Cass., xlii., p. 236.) In the early ages of the history of Rome the pontiffs were elected by the kings, but after the overthrow of the kingly power the college exercised the right of co-optation (Dionys. Hal., ii. 73; Livy, xl. 42), until 104 B.C., when the right of electing persons to the office of pontiff was partly transferred to the people by the Domitian law; for, according to this law, the co-optation of the college was still necessary as a religious ceremony, after a person had been elected by the people. (Cic., 'in Rull.,' ii. 7.) When Sulla increased the number of pontiffs, he, at the same time, gave back to the college the full right of co-optation; the tribune Labienus, indeed, in 63 B.C., revived the Domitian law, but it was again abolished by Antony. (Dion Cass., xliv., p. 305.) The chief pontiff, who at first seems to have been appointed by the kings, was afterwards elected by the curies in the comitis curiata, and generally taken from the number of the pontiffs themselves, or from those who had held the highest offices of the state. (Liv. xl. 42; comp. with xxv. 5.) The functions of the college of pontiffs were not limited to the service of any particular deity. It had very extensive powers, and not only had the superintendence over all matters of religion, but even those which were in any degree connected with it, such as marriage, adoption by adrogation (Cic., 'Pro. Dom.,' 13), and funeral ceremonies. The pontiffs had a direct judicial power, and might, in some instances, even punish with death. (Cic., 'De Legg.,' ii. 9; comp. with Liv. xxii. 57.) The chief pontiff, whose office, like that of the other pontiffs, was for life, and who was not responsible either to the senate or the people, was supreme judge in all matters relating to, or connected with, religion; and from his sentence an appeal could only be made to the people in cases where a magistrate was fined, or his person seized (Liv. xl. 42); for the few instances of later times, where a tribune interposed and modified the sentence of the chief pontiff, seem to have been anomalies. His powers extended over magistrates as well as private individuals; and the former, if acting contrary to the laws of religion, might be fined (Liv. xxvii. 51; Cic., 'Philip,' xi. 8; Liv. xl. 42), or compelled by the chief pontiff to resign their office. It also formed part of his duties to regulate the calendar, and to interpret the ceremonial laws, for he and his college were in the exclusive possession of the ritual books (commentarii sacrorum or libri pontificales), in which all religious rites were laid down, and which at all times were considered as decisive upon any point which belonged to their jurisdiction; and consequently, they decided what auguries were to be received. The rules and regulations which guided the pontifices formed a large body of law, called 'Jus Pontificium.' (Cic., 'De Or.,' i. 43; iii. 33; 'Pro Dom.,' 13.) Among the external distinctions of the pontiffs, were the toga prætexta, and the tutulus or galerus, a cap of a conical form adorned with an apex. They lived in public buildings on the Viâ Sacra (Suet., 'Cæs.,' 46), or in the house of Numa (Plin., 'Epist.,' iv. 11). The chief pontiff was not permitted to quit Italy (a rule first violated by P. Licinius Crassus); he was not allowed either to see or to touch a corpse, or even to visit a house in which there was a dead body. After the death of his wife, who, according to the laws, should always be a woman of great moral virtue, he was not permitted to marry again. (Plin., 'Paneg.,' 83.) He also elected the vestal virgins, and superintended their moral conduct. From the time that Augustus assumed the office of chief pontiff, it was held by all his successors down to the time of Gratianus, who disdained this dignity. (Zosim., iv. 36, 9.) The title P.M., or Pon. M., Pontifex Maximus, appears on some of the coins of the Roman emperors. The mode of living of the Roman pontiffs does not seem to have been much more sober or simple than that of some priests of modern times. (Horat., 'Od.,' ii. 14, 26, ff.; Martial, 'Epigr.,' xii. 48, 12; Macrob., 'Sat.,' ii. 9.)

In the Roman Catholic church, the Pope has the title of Sovereign Pontiff. In the Liturgy of that church all prelates are styled Pontiffs. The book of ceremonials for the administration of the sacrament is called the pontifical; and the pontificate is alike the dignity of the pope, and the period during which he occupies the seat. It is observable that the early Christian priestly communities were frequently the founders or guardians of bridges.

PONTOON, or PONTON. This term is employed by the French to signify any barge or flat-bottomed boat; but in this country it is confined to those vessels which are used in the formation of floating-bridges for military purposes.

The conveyance of an army with its artillery and baggage across the rivers which intersect its line of march is one of the most difficult as well as the most important operations in military tactics. The occupation of an advantageous position in a given time, when the army acts offensively, materially influences the success of a campaign; and the favourable moment may be lost, if means should not be at hand to overcome the obstacle presented by a deep and rapid stream. But the failure or insufficiency of such means must be attended with the most fatal consequences to a retreating army, when it is prevented by a river from getting beyond the reach of an enemy; for its safety, in this case, depends upon the power of passing the river without delay, and upon the removal or destruction of the bridge immediately afterwards.

History presents us with innumerable instances, both of the ruin of armies caused by the want of means to make good their passage across rivers, and of the protection which armies have received when rivers have interposed between them and the superior forces of an enemy. To take an example from modern warfare, it may be observed, that during the retreat of Napoleon from Moscow, had it not been for the extraordinary care used by the chief of the French engineers to preserve the materials requisite for the formation of a bridge, the whole of the army must have been captured or destroyed on the banks of the Beresina.

The rapidity of warlike operations seldom allows bridges, at least those of considerable magnitude, to be constructed on piles or piers; and perhaps the only military work of this nature which need be hinted at is that which was formed by Cæsar across the Rhine. [BRIDGE.]

Bridges consisting of timber platforms supported on floating vessels appear to have been in use in all ages. But those which were thrown by Darius across the Bosphorus, and subsequently over the Danube, and that which was formed by the order of Xerxes over the Hellespont at the time of his unfortunate expedition into Europe, deserve to be considered as the most famous works of that nature which were constructed by the ancients: and Herodotus, who has preserved (lib. iv., 88) the name of the Greek engineer employed on the two first, has also given a full description of the last (vii. 36). He states that 360 vessels, anchored both at the head and stern, were disposed in parallel directions across the strait with their keels in the direction of the current, in order to diminish the strain on their cables; and that parallel to this line, but nearer the Archipelago, was another consisting of 314 vessels, similarly disposed. The vessels were connected together by cables, over which was laid a platform of planks covered with a bed of earth, and there was a rail on each side. Xenophon also relates ('Anabasis,' lib. ii., c. 4) that the Greeks, in their retreat, passed the Tigris by means of a bridge which was supported on thirty-seven vessels. Of such boat-bridges for military purposes the most remarkable, in modern times, is that which was formed, by the engineers of the British army, across the Adour, in the south of France, in 1814. It consisted of twenty-five chasse-marées, varying in burthen from 20 to 40 tons, which were moored at distances of nearly 40 feet from centre to centre. At first, hawsers resting on their decks were strained by capstans and made fast to some heavy guns which were laid behind the retaining walls on the sides of the river, and these ropes carried the planks which formed the roadway; but after a few weeks they were removed, and replaced by timbers, which from their steadiness were found preferable. The breadth of the river at the place where the bridge was formed is 810 feet, and booms were moored across, both above and below the bridge, for its protection.

The precise period at which pontoons, or flat-bottomed vessels, were first employed to support a bridge is unknown. Folard observes, in his observations on the fifth book of Polybius, that for passing rivers the Germans in his time used vessels formed of timber frames covered with leather: he adds that the Dutch troops had pontoons of wood covered with tin, and that the French took some of them at the battle of Fleurus, which was gained, in 1698, by the Maréchal de Luxembourg over the Prince of Waldeck. Mention is frequently made of pontoon-bridges, both in Germany and Italy, in the beginning of the 18th century, particularly during the campaigns of Marlborough; and, from the speed with which they are said to have been executed when required, it is probable that a corps of men was then particularly employed in that branch of service.

The pontoons employed during the war against Napoleon I. differed but little from those mentioned above. They were of metal over a light framework of wood tinned inside; they were from 17 to 21 feet long, from 4 to 5 feet broad, and from 2 feet to 2 feet 3 inches deep. In the formation of the bridge, a rope was tightly stretched across the river; the vessels were then rowed to their places, and each was made fast at one end to the rope; another rope was then stretched across the river, parallel to the former, at the opposite ends of the pontoons, and to this rope those ends were made fast. When a strong current set obliquely across the river, the sides of every two pontoons were sometimes connected together by rope braces stretched diagonally across the intervals, in order that the effect of the current upon each might be counteracted by a like effect on the next; and in very rapid streams anchors were also thrown out from each or from every second or third pontoon, according to circumstances.

Timber-baulks, or joists, were then laid from the shore to the first pontoon, from that to the next, and so on, at intervals from each other depending upon the breadth of the bridge or the weight to be supported. Every two in the direction of the length were attached together by a bolt, which allowed the bridge to yield to the rise or fall of the water. Above these timbers were placed the chesses, or flooring-planks, close together and perpendicular to the length of the bridge; and these were kept down by a riband or a plank, which was fastened over their extremities on each side of the bridge.

General Sir Charles (then Colonel) Pasley, to whom the department of military engineering in the British service is so much indebted for the improvements which he has introduced into every branch of art connected with practical fortification and siege operations, has proposed a description of pontoon. The form of the old pontoons rendering them difficult to manage in the water, and their great weight, when it was necessary to transport them from place to place by land, causing them to be a serious encumbrance to an army on its march, that officer was led to construct the pontoons in the form of canoes, with decks, each end being shaped like the head of a boat, in order that they might be easily moved through the water by rowing, with either end foremost. They are constructed of light timber frames, covered, except the deck, with sheet copper; and each vessel is formed in two equal parts by transverse partitions, so that the demi-pontoons may be separated from each other when the bridge is to be conveyed on carriages by land with the army. When in the water, the parts are connected together by a rope, which passes through two perforations in the keel, near the place of junction, and by a rectangular frame of wood, which is laid along the deck, and attached to it by lashings. Each half-vessel is also divided into two compartments by a partition; and small pumps are provided, by which the pontoon may for a time be kept afloat, should a hole be made in its side by a shot or by any other accident.

Sir James Colleton, some years since, invented pontoons of wood of a cylindrical form, some o which have been occasionally employed in experimental operations; and cylindrical pontoons of tin, which were subsequently invented by the late General Blanchard, were introduced into the service. These last have hemispherical ends, and are divided both longitudinally and transversely into several compartments by partitions of tin, both to increase their strength and to prevent them from sinking in the water in the event of their being accidentally perforated in any part. They possess the advantages of great lightness and buoyancy; but they have not the durability of copper vessels, and they must be very liable to be injured when transported by land, particularly if a march should take place under a hot sun.

In 1836 the comparative merits of General Pasley's and General Blanchard's pontoons were tried upon the Medway, when large bodies of infantry and cavalry, besides three pieces of artillery, were made to pass over the river on bridges supported by vessels of the two kinds. The order of march was purposely such as to subject the bridges to the severest strains; and a superiority of steadiness on this occasion appears to have led to a preference in favour of the pontoons proposed by the last-mentioned officer.

The breadth and depth of one of General Pasley's pontoons are 2 ft. 8 in. The diameter of one of General Blanchard's cylinders is 2 ft. 8 in. The length of the former kind of pontoons is 22 ft.; of the latter, 24 ft. 6 in.

The manner of forming the bridge, with both kinds, is nearly the same. A rectangular frame, whose length is about equal to the breadth of the platform for the intended bridge (12 feet), is laid down longitudinally on the deck of the canoe, or on the surface of the cylinder, and is kept in its place by rope-lashings; on the upper surface of this frame, in the direction of its breadth, are nailed pieces of wood in pairs, at equal intervals; the distance between every two in each pair being little more than equal to the breadth of a baulk, or joist (2½ inches), one extremity of which is to be received between them, and the number of pairs being equal to the number of baulks which are to support the chesses or planks forming the roadway. A raft is formed with two of these pontoons, by placing them parallel to each other, at a distance, from centre to centre, equal to about 12½ feet; the ends of two baulks, or transoms, as they are called, are made to rest upon the frames before mentioned, the distance between them being equal to the intended breadth of the bridge, and they are kept steady by having near each extremity a hole bored through them, into which enters an iron pin fixed vertically for the purpose in the frame: they are also made fast to the pontoons by ropes passing through rings on the decks. Three or more baulks are then laid down parallel to the transoms, with their extremities confined between the cross-pieces nailed to the frames as above said: the chesses are laid close together above them, and their ends are kept down by ribands, which are attached to the transoms by lashings passing over them, and under the latter, at intervals. In those ribands are fixed rowlock pins; and when the bridge is not formed, the ribands being then placed parallel to the lengths of the pontoons, at the sides of the raft, the latter may be moved on the water by the oars.

When the bridge is to be formed, a certain number of such rafts are rowed to their stations in a line across the river, the lengths of the pontoons being parallel to the banks, and there anchored; the distances between the nearest pontoons in two rafts being equal to that between the two pontoons in each raft. Then each raft carrying the materials which are to make a platform over the water between itself and the next, such platform is laid down in a manner similar to that which is employed in laying down the platform of the raft; and from each of the extreme pontoons a like platform is extended to the shore of the river.

When the banks are favourable, the complement of men attached to each raft of two pontoons—namely, one non-commissioned officer and six privates—can dismount two vessels and their stores from the carriages, launch them, and form the raft in a quarter of an hour. All the rafts being put together at the same time, the whole bridge may be formed in another quarter of an hour. After the passage has been effected, the bridge can be dismantled in eight minutes; the rafts can then be taken to pieces, and the vessels and stores re-packed on the carriages in a quarter of an hour.

In order to convey the pontoons with an army, each is placed, with all its accompaniments, on a four-wheeled carriage. General Pasley proposes to use only a cart with two wheels for each pontoon, the latter being separated into two demi-pontoons, which are placed side by side above their stores. The shortness of these carriages enables them to be turned within a smaller space than would be required for a four-wheeled waggon; but the weight on the shaft-horse in hilly countries would be so great that it would be hardly practicable.

The inconvenience attending the transport of pontoons, or the necessity of passing a river when they are not at hand, has induced commanders of armies to have recourse to bridges supported on rafts of timber or on empty casks, which in Europe can always be procured. Each raft may consist of four or more rough trunks of trees lashed together, and may be retained in its place by anchors, or by being made fast to a rope stretched across the river: the baulks and chesses are applied as in a pontoon bridge. Perhaps the greatest raft-bridge ever formed is that which was executed by General Sokolniki over the Niemen at Grodno, in 1792. Trunks of trees from 50 to 60 feet long, and from 20 to 28 inches in diameter, were united by tens, and every ten were bound together at both ends by transverse braces, so as to form a raft, which, as all the large ends of the trees were placed contiguously, resembled the voussoir of a bridge. All the voussoirs, 57 in number, were placed in the river, side by side, in an arc of a circle having its convexity towards the upper part of the river; and a sort of key-voussoir was formed by a vessel 116 feet long and 22 feet wide, which was moored in the river where the current was the most rapid. Baulks and planks were placed, as usual, above the rafts to form the road. The breadth of the river at that place is about 1080 feet. (Berard, 'Equilibre des Voûtes.')

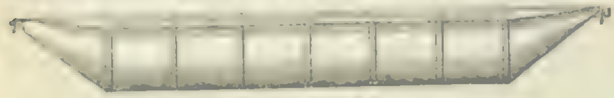
A strong raft-bridge was formed by the Russians and Prussians over the Elbe, near Dresden, in 1813: one course of logs disposed parallelwise to each other formed the bottom of each raft; cross-timbers were laid above these; and over them was a third course of timbers, each placed above the interval between two of those below it. The timbers were well lashed together; a strong cable was stretched across the river on each side of the bridge, which was further retained in its place by anchors, and a road was formed of planks as usual. While the British army was serving in Spain during the Peninsular war, the roofs of buildings were occasionally taken to form rafts: the rafters served as baulks; and, for want of nails, the planks were kept down to the timbers by ribands formed of young trees split in two longitudinally and tied by willow twigs.

A cask bridge is sometimes formed in the following manner:—A certain number of casks are placed side by side, so as to form a sort of floating pier, having their axes in horizontal positions; the casks are lashed to two gunwale timbers, as they are called, which extend along the upper side of the pier at the extremities of the casks: two of these piers are placed at an interval of about 10 feet from each other, and they are connected together by the baulks which support the platform. As many of these rafts are prepared as may be necessary, they are rowed to their places in the line, and the bridge is formed in the same manner as the pontoon bridge above described.

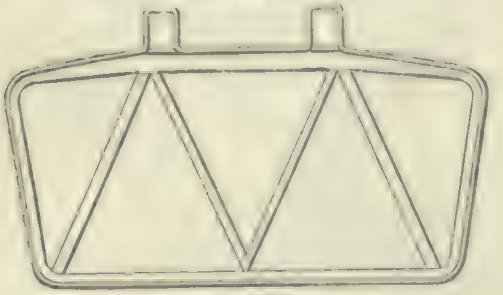
When the formation of a bridge extending over a river from one bank to another becomes impossible, numerous expedients are had recourse to for conveying troops across by means of what are called flying or moving bridges. We learn from Arrian that the army of Alexander passed the Indus by means of boats and rafts of timber, the latter being supported on bags made of skin and inflated with air; and in a similar manner the infantry of Hannibal is said by Livy to have crossed the Rhine. In India, at the present time, the passage of rivers is often effected by means of basket boats, which are formed of split bamboos and covered with half dressed hides. Each vessel is said to be capable of containing about 30 men.

In 1811, Captain Squires, of the Engineers, formed a bridge over the Guadiana by fixing trestle piers in the shallow parts of the river and mooring boats in the middle: but just as the bridge was finished, the river swelled and carried away the trestles. The boats were then converted into flying bridges, to convey over the cavalry and artillery; and a slight narrow bridge was made for the infantry with pontoons and casks, the latter being taken from the neighbouring villages.

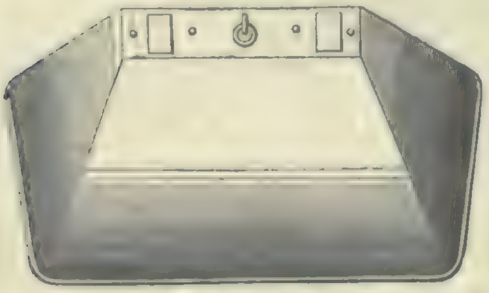
Captain Fowke, R.E., has lately invented a pontoon which appears likely to supersede those now in use. It is a *boat* pontoon, the boats consisting of canvas on wooden frames. The accompanying drawings will explain their form. The advantages claimed for them by their inventor are best explained in his own words ('Royal Engineer Corps Papers,' vol. vii.):—



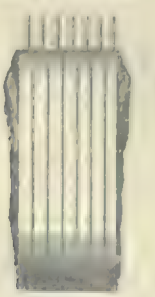
Pontoon expanded.



Section of Pontoon.



Stern of Pontoon.



Pontoon folded.

1. The buoyancy is nearly double.

2. The weight is less than half.

3. The length on the line of march is less than half.

4. The first cost is only two-fifths.

5. The bulk, when packed, is only one-seventh.

6. The height of the roadway above the water is increased.

7. The stability is greater, and the tendency of the bridge to oscillate from side to side is avoided; this motion is caused by the ends of the pontoons being alternately immersed or plunged downwards, and will, *cæteris paribus*, always increase as the vertical section of the pontoon approaches the form of the solid of least resistance; and as a flat surface offers considerably more resistance than one with a circular or curved section, it follows that, independently of all considerations of buoyancy, the canvas pontoon will excel in stability from this cause.

8. The liability to damage from shot is diminished, as a grape shot or musket ball, which would make a serious wound in metal, will merely perforate the canvas with a very small round hole.

9. In the case of a pontoon grounding while under a heavy weight, where the metal one would be put quite hors de combat, the worst that would be likely to happen to a canvas one would be the fracture of a frame or two, which would not occasion a leak, and could easily and quickly be repaired.

10. The pontoon can be bailed out easily, even while in bridge; and this operation is no longer dependent on the small pumps, always so slow in action, and so likely to choke and get out of order.

11. The weight of every individual piece of the bridge is diminished, as well as the number of pieces, and the superstructure is simplified; in forming a bridge, one operation, that of lashing on the saddles (often a difficult one), is entirely avoided.

12. It would appear from the considerations in the last paragraph that each waggon load could be formed into bridge with at least equal celerity as one load of the service equipment, and, if so, there will be a saving of nearly half the time in forming a bridge, eight waggon loads of the canvas pontoon forming as much bridge as fifteen of the service one.

13. The durability is greater: one of the greatest advantages which the canvas pontoon seems to possess over that now in use (as far as can be judged at present) is that while its liability to injury is diminished, in point of durability it appears to be very superior to the latter pontoon, whether on the march, in water, or in store. Jolting on the march, or rolling over uneven ground, or down a stony beach, is almost certain to start one or more joints of the metal pontoon, slightly perhaps, but sufficiently to admit a small quantity of water, so small as to be disregarded; on being brought out of the water the pontoon is then stored with its inside and all its delicate framework quite wet, and the process of corrosion thus commenced, tends still further to weaken the joints and render them even more liable to such accidents; and this accounts for the fact that few, if any, of the present pontoons have ever gone through a summer's practice at Chatham without having to be put at least once into the hands of the tinman for repair. The canvas pontoon, on the contrary, from the elastic and yielding nature of its materials, is less liable to injury on shore; running it on piles or rocks has absolutely no permanent effect on it, for a like reason; and on the march it is enclosed in its own defensive armour of hoops, which effectually protects it from injury. As an example of the durability of such a construction, may be cited the case of the fishing-boats on the west coast of Galway, which are made of canvas stretched over a wooden skeleton, without any external protection, and which stand all weather out at sea for many years. As to durability in store, I have had an opportunity of very carefully examining eight canvas pontoons in store at Chatham; of these one was constructed in the beginning of 1853, two more in the course of the same year, and three in the early part of 1855; and although they have all been out repeatedly, and the latter frequently, I think it will be found that they are not deteriorated in any respect: the oldest of all would be perhaps the better of a coat of boiled oil, but nothing more is necessary for any of them.

14. The canvas pontoon could without much difficulty be made in the field, such materials as hoops of casks, canvas, poles, and oil, being almost always procurable; and one or more extra waggons may be attached to each bridge-train, carrying nine pontoons each, to be available in case of emergency.

15. A *single* pontoon can be used and pulled as a *boat*, for laying out anchors, &c., and as it is stable in the water it may be pulled or poled into its place in the bridge.

Three pontoons, similar to the one described, have been constructed at Chatham, and subjected to some severe tests as to buoyancy; in one instance a heavy 32-pounder was put on a raft of two pontoons and the load was increased by men and sandbags to 95 cwt., with which load it was floated out into the Medway, and it bore it without any apparent strain, and with considerable spare buoyancy. The only point in which these pontoons appeared to be inferior to those in use was in the single one of speed in rowing, the expression in the report being that they seemed to be too light to row well; this appears to me to be a matter of such small consideration that I should not have noticed it but for an idea that seems to prevail that the quicker a pontoon rows the better it will ride at anchor in swift currents or rough water, and which every sailor knows to be fallacious, the fact being that the safe riding depends on the *vertical* angle of the bow, while the speed is mainly influenced by the *horizontal* angle or "lines;" a vessel with a bow that is straight up and down will bury her head much more than one with a "flare bow," that is, one which projects beyond the waterline, even though the former may have the superiority in point of speed.

(For many interesting particulars relating to the passage of rivers in military operations, see Sir Howard Douglas, *On Military Bridges*.)

POOR LAWS. According to Dr. Johnson the term pauper means a poor person; one who receives alms. The term, however, Mr. Glen says, is hardly known to the law, and very rarely occurs in any of the statutes relating to the relief of the poor. The word "poor" by the 4 & 5 Wm. IV. c. 76, s. 109, is to be construed "to include any *pauper* or poor or indigent person applying for or receiving relief from the poor rates in England or Wales, or chargeable thereto;" and in the Lunacy Act, 16 & 17 Vict. c. 97, s. 132, the word pauper "shall mean every person maintained wholly or in part by or chargeable to any parish, union, or county." The latter is the most convenient use of the term, and the word "pauper" will be so understood in this article.

Those who are ordinarily designated paupers are only one class or division among several who are in the condition of poverty. The poor, as distinguished from the paupers, may be distributed into three classes. 1. Persons without capital, who, being capable of labour, and finding employment, are able to obtain the means of subsistence and no more. 2. Mendicants, capable of labouring, but who will not work, and subsist by obtaining contributions from the humane and charitable. 3. Persons destitute through sickness, infirmity, desertion, or any other cause, and relieved by private charity.

The great object of the earlier efforts in pauper legislation was the restraint of vagrancy. The 12 Richard II. c. 7 (1388), prohibits any labourer from quitting his dwelling-place without a testimonial from a justice of the peace, showing reasonable cause for his going, and without such a testimonial any such wanderer might be apprehended and put in the stocks. Impotent persons were to remain in the towns where they were dwelling at the passing of the Act, provided the inhabitants would support them; otherwise they were to go to the places of their birth, to be there supported. By Acts passed in the 11 & 19 of Henry VII. (1495 and 1504) impotent beggars were required to go to the hundred where they had last dwelt for three years, or where they were born, and were forbidden to beg elsewhere. By the Act 22 Henry VIII. c. 12 (1531), justices were directed to assign to impotent poor persons a district within which they might beg, and beyond which they were forbidden to beg, under pain of being imprisoned and kept in the stocks on bread and water. Able-bodied beggars were to be whipped and forced to return to their place of birth, or where they had last lived for three years.

These Acts appear to have had no permanent effect in repressing vagrancy. An Act passed in 1536 (27 Henry VIII. c. 25) is the first by which voluntary charity was converted into compulsory payment. It enacts that the head officers of every parish to which the impotent or able-bodied poor may resort under the provisions of the Act of 1531, shall receive and keep them, so that none shall be compelled to beg openly. The able-bodied were to be kept to constant labour, and every parish making default was to forfeit twenty shillings a month. The money required for the support of the poor was to be collected partly by the head officers of corporate towns and the churchwardens of parishes, and partly was to be derived from collections in the churches, and on various occasions where the clergy had opportunities for exhorting the people to charity. Almsgiving beyond the town or parish was prohibited, on forfeiture of ten times the amount given. A "sturdy beggar" was to be whipped the first time he was detected in begging; to have his right ear cropped for the second offence; and if again guilty of begging, was to be indicted "for wandering, loitering, and idleness," and if convicted was "to suffer execution of death as a felon and an enemy of the commonwealth." The severity of this Act prevented its execution, and it was repealed by 1 Edward VI. c. 3 (1547). Under this statute every able-bodied person who should not apply himself to some honest labour, or offer to serve for even meat and drink, was to be taken for a vagabond, branded on the shoulder, and adjudged a slave for two years to any one who shall demand him, to be fed on bread and water and refuse meat, and made to work by being beaten, chained, or otherwise treated. If he ran away during the two years, he was to be branded on the cheek, and adjudged a slave for life, and if he ran away again, he was to suffer death as a felon. If not demanded as a slave, he was to be kept to hard labour on the highways in chains. The impotent poor were to be passed to their place of birth or settlement, from the hands of one parish constable to those of another. This statute was repealed three years after, and that of 1531 was revived. In 1551 an Act was passed directing that a book should be kept in every parish, containing the names of the householders and of the impotent poor; that collectors of alms should be appointed who should "gently ask every man and woman what they of their charity will give weekly to the relief of the poor." If any one able to give should refuse or discourage others from giving, the ministers and churchwardens were to exhort him, and, failing of success, the bishop was to admonish him on the subject. This Act, and another made to enforce it, which was passed in 1555, were wholly ineffectual, and in 1563 it was re-enacted (5 Eliz. c. 3), with the addition that any person able to contribute and refusing should be cited by the bishop to appear at the next sessions before the justices, where, if he would not be persuaded to give, the justices were to tax him according to their discretion, and on his refusal he was to be committed to jail until the sum taxed should be paid, with all arrears.

The next statute on the subject, which was passed in 1572 (14 Eliz. c. 5), shows how ineffectual the former statutes had been. It enacted that all rogues, vagabonds, and sturdy beggars, including in this description "all persons whole and mighty in body, able to labour, not having land or master, nor using any lawful merchandise, craft, or mystery, and all common labourers, able in body, loitering and refusing to work for such reasonable wages as is commonly given," should "for the first offence be grievously whipped, and burned through the gristle of the right ear with a hot iron of the compass of an inch about;" for the second, should be deemed felons; and for the third, should suffer death as felons, without benefit of clergy. For the relief and sustentation of the aged and impotent poor, the justices of the peace within their several districts were "by their good discretion" to tax and assess all the inhabitants dwelling therein. Any one refusing to contribute was to be imprisoned until he should comply with the assessment. By the statutes 39 of Elizabeth, cc. 3 and 4 (1598), every able-bodied person refusing to work for the ordinary wages was to be "openly whipped until his body be bloody, and forthwith sent, from parish to parish, the most straight way to the parish where he was born, there to put himself to labour as a true subject ought to do."

The next Act on this subject, the 43 Elizabeth, c. 2, has been in operation from the time of its enactment, in 1601, to the present day. An entire change in the mode of administration which had grown up under its provisions was however effected by the Poor-Law Amendment Act (4 & 5 Wm. IV. c. 76), which was passed in 1834. During that long period many abuses crept into the administration of the laws relating to the poor, so that in practice their operation was subversive of the morals of the most numerous class, and injurious to the welfare of the whole country. In its original provisions, the Act of Elizabeth directed the overseers of the poor in every parish to "take order for setting to work the children of all such parents as shall not be thought able to maintain their children," as well as all such persons as, having no means to maintain them, use no ordinary trade to get their living by. For this purpose they were empowered "to raise, weekly or otherwise, by taxation of every inhabitant, parson, vicar, and other, and of every occupier of lands, houses, tithes, mines, &c., such sums of money as they shall require for providing a sufficient stock of flax, hemp, wool, and other ware or stuff, to set the poor on work, and also competent sums for relief of lame, blind, old, and impotent persons, and for putting out children as apprentices." Power was given to justices to send to the house of correction or common jail all persons who would not work. The churchwardens and overseers were further empowered to build poor-houses, at the charge of the parish, for the reception of the impotent poor only. The justices were further empowered to assess all persons being of sufficient ability for the relief and maintenance of their children, grandchildren, and parents. The parish officers were also empowered to bind as apprentices any children who should be chargeable to the parish.

These simple provisions were in course of time greatly perverted, and so many abuses were engrafted upon the statute, that it became an instrument of more general demoralisation than was ever sanctioned by legislative authority. It would greatly exceed any reasonable limits to trace the progress of these abuses. The most injurious practice was that which was established about the year 1795, when, in order to meet the pressure upon the labouring population caused by the high price of provisions, an allowance was made out of the parish fund to every labourer in proportion to the number of his family, and without reference to his being employed or without employment. This allowance fluctuated with the price of flour, and the scale was so adjusted as to return to each family the sum which a given quantity of flour would cost beyond the price in years of ordinary abundance. If things had been left to take their course in England, as they were in Scotland, the labourer's wages would have enabled him to purchase the same, or nearly the same, amount of provisions and other articles of necessary consumption as before the advance, and when the necessity for such a rise in wages had passed away everything would have reverted to its former state. Under the allowance system the labourer was made to receive a part of his earnings in the form of a parish gift, and as the fund out of which it was provided was raised from the contributions of those who did not employ labourers, as well as of those who did, it followed that the labourers were degraded from the condition of honourable independence to that of parish paupers, and that their employers, being able in part to burden others with the payment for their labour, had a direct interest in perpetuating the system. Accordingly it was found that a constant and rapid deterioration took place in the character of the labouring agricultural population, and that they became unable to obtain a rate of wages adequate to their support without parish relief, however moderate might be the prices of the necessaries of life.

There are no accounts of the sums levied year by year in England

and Wales for the relief of the poor before the beginning of the present century. The average expenditure for each of the three years 1783-4 and 5, was 1,912,241*l.*; the earliest account after that date is for 1801, when the expenditure amounted to 4,017,871*l.*, the assessments having been more than doubled in 17 years. It will be seen from the following table how little connection there has been since that time between the sums expended for relief and the price of corn :—

Years.	Sums expended for the Relief of the Poor.	Average Price of Wheat per Quarter.	
	£	s.	d.
1813	6,656,106	125	6
1814	6,294,581	108	9

1857	5,898,756	65	3
1858	5,878,542	53	10
1859	5,558,689	42	9

The extent to which the pauperising of the labourers of England was carried had long been viewed with alarm, and had formed the subject of many parliamentary inquiries, but without producing any substantial amendment, until, in 1832, a commission was appointed by the crown, consisting of the bishops of London and Chester, Mr. Sturges Bourne, Mr. Senior, and five other gentlemen, under whose direction inquiries were carried on throughout England and Wales, and the actual condition of the labouring class in every parish was ascertained, with the view of showing the evils of the existing practice, and of suggesting some remedy. The labour of this inquiry was exceedingly great; but in a comparatively short time a report was presented by the commissioners, which completely explained the operation of the law as administered, with its effects upon different classes, and suggested remedial measures. This report was presented in February, 1834, and was followed by the passing, in August, 1834, of the Poor-Law Amendment Act, in which the principal recommendations of the commissioners were embodied.

The chief provisions of this law are—the establishment of the Poor-Law Commissioners (now the Poor Law Board) to exercise a controlling authority over the administration of relief to the destitute by the local authorities. The administration of relief to the poor is placed under the control of the commissioners, who make rules and regulations for the purpose, which are binding upon all the local bodies. They are empowered to order workhouses to be built, hired, altered, or enlarged, with the consent of the majority of the board of guardians. One very important power given to them was that of uniting several parishes for the purposes of a more effective and economical administration of poor relief. These united parishes, or unions, are managed by boards of guardians annually elected by the ratepayers and owners of property of the various parishes, but the masters of workhouses and other paid officers, though appointed by the guardians, are under the orders of the commissioners, and removable by them. The system of paying wages partly out of poor-rates is discontinued, and except in extraordinary cases, as to which the commissioners are the judges, relief is only to be given to able-bodied persons or to their families within the walls of the workhouse. Another branch of the poor-law, which was materially altered by the Act of 1834, was that relating to illegitimate children. And the law upon this subject has since been further altered by the 7 & 8 Vict. c. 101, and indeed entirely disconnected with the Poor Laws, the mother being now left to enforce her civil remedy against the father of the child.

The number of unions formed, and places in which the rules and regulations of the Poor Law Board are in force, to Lady-day, 1860, is 646, including 14,427 parishes, with a population of 17,670,938 souls.

It will be convenient to state how the law stood previously to the passing of the Poor-Law Amendment Act (4 & 5 Wm. IV. c. 76), and then to notice more particularly some of its leading provisions.

Every indigent person, whether a native or a foreigner, being in any district of England or Wales, in which a fund is raised for the maintenance of the poor, has a right to be supplied with the necessaries of life out of that fund. This right depends on statute, and principally on the 43 Eliz. c. 2, which enacts that the churchwardens of every parish, and four, three, or two substantial householders there, to be nominated yearly under the hands and seals of two or more justices of the peace, shall be called overseers of the poor. [OVERSEERS.] Under this statute overseers could be appointed for parishes only. This proved very insufficient, because many large and populous districts were not situate within any parish, and consequently no overseers whatever could be appointed for them; and also because many parishes themselves were of such magnitude that one set of overseers could not properly attend to all the poor. To supply this defect, the 13 & 14 Car. II. c. 12, authorised the appointment of overseers in any township that was either extra-parochial or was part of a parish so large as to require distinct sets of officers for the management of its poor. The 20 Vict. c. 19 made further provision for the appointment of overseers for extra-parochial places.

It is the duty of these overseers to raise the fund for the relief of the poor of their district. This fund, which is called the poor-rate, they are directed by the statute of Eliz. in parishes, and by the statute of Car. II. in townships, to raise "weekly or otherwise, by taxation of every inhabitant, parson, vicar, and other, and every occupier of lands, houses, tithes impropriate, propriations of tithes, coal-mines or saleable underwoods in the said parish, in such competent sum and sums of money as they shall think fit, &c., according to the ability of the parish."

The rate may be made according to the exigencies of the place, which, whether parish or township, may conveniently in either case be called a parish, for any period not less than a week nor exceeding a year. The rate, which is made in writing, gives the names of the persons rated, a description of the property for which they are rated, and the amount payable by them; it contains also a declaration, signed by the parish officers, that the rate is, to the best of their belief, correct, and that they have used their best endeavours to make it so. The rate so made and signed must be taken to two justices for their assent, which is called the allowance of the rate, and public notice of such allowance must be given on the Sunday following, or the rate will be entirely void.

As the statute expressly mentions both inhabitants and occupiers, inhabitants were held liable to be rated in proportion to their ability within the parish, although they had no property there which was capable of occupation, and occupiers of property therein were held liable although they resided elsewhere. Accordingly both real corporeal property and personal property within the parish may be assessed, as constituting "the ability of the parish;" real corporeal property, as land or houses, may be assessed, wheresoever the occupier resides, and personal property, if the owner is resident within the parish. Incorporeal real property, since it is not the subject of occupation, seems not to be rateable unless incidentally, when, as in the case of the tolls of a canal, it is, as it were, annexed to and enhances the value of corporeal real property, which is the subject of occupation. As it is the occupier and not the owner of real corporeal property who is rated for it, it will be obvious that the term "real property" is not used in the poor-laws according to its strict legal sense, and that the occupier of a house is rated for it, although he has a mere chattel interest in it. The term "personal property" is also used in a restricted sense; it denotes stock in trade, and such things as are not at all of the nature of realty, and excludes chattels real. The assessment is laid in respect of the revenue or annual profit of the property rated, whether real or personal. Such property therefore as is incapable of yielding profit is not rateable. The assessment upon land and houses, &c., is calculated upon an estimate of their net annual value, which is defined to be the rent at which they would let from year to year, free of all tenant's rates and taxes, and tithe commutation rent-charge, if any, and deducting the probable average of annual costs of repairs, insurance, and any other expenses which may be necessary to maintain the premises in a state to command such rent. Personal property was not rated unless it had, as it were, a local existence; and therefore neither stock in the funds nor money was rateable. Furniture also was exempted, because it yielded no profit. In practice the only kind of personal property ever rated, and that in very few places, was stock in trade and ships. The rating of this species of property was attended with many disadvantages. The rate was to be made on the profit, which was defined to be not the whole profit, but the excess after payment of debts. Thus it was nearly impossible to ascertain the rateable amount of such property, and the proprietor might always evade the tax by residing out of the parish. So long however as personal property was rateable by law, the omission of it in the rate was a ground of appeal, because all persons liable are to be rated equally according to their ability. The inconvenience of this state of things induced the legislature to enact by 3 & 4 Vict. c. 89 that no inhabitant should be rated for his stock in trade or other property. The word "inhabitant," may now be considered as struck out of the statute of Elizabeth; nobody will have to contribute henceforward to the poor-rate except in his character of occupier. Personal property therefore is no longer rateable; but nevertheless the exemption depends upon the passing annually of an act of parliament continuing the exemption.

If a parish is unable to furnish a sufficient sum for the maintenance of its poor, any other parish in the same hundred, with the sanction of two justices, or in any other part of the county, with the sanction of the justices at quarter-sessions, may be called upon to assist the less solvent parish. This is called rating parishes in aid.

The overseers are to collect the rate from the persons rated. If a person rated do not pay when called upon, the overseers may obtain a summons, requiring him to show cause why a warrant should not issue to levy the rate by distress and sale of his goods; and, if no sufficient cause is shown, the payment is enforced accordingly. The party so summoned may show for cause that the rate itself is void, or that he is not liable; he may also, with the consent of the overseers, be excused, if it appear that he is unable to pay through poverty. He may also appeal against the rate, and notice of appeal deprives the magistrates of their jurisdiction to distrain until the appeal is decided, unless the objection is solely on the ground of over-charge, in which case the warrant may issue for such a sum as the property was rated at in the last valid rate. The appeal against the rate on the ground of inequality, unfairness, or incorrectness in the valuation of the property rated may be to justices at special sessions, from whose decision a second appeal lies to the general quarter-sessions. The appeal, on the above grounds, may also be taken to the quarter-sessions in the first instance. If the objection be to the principle of the rate itself, or it is intended to dispute the liability of the property to be rated, the appeal lies to the quarter-sessions only. In all these cases of appeal, notice of appeal and of the precise objections to the rate must be given to the parish-officers, and also to any rated inhabitants that may be interested in opposing the appellant, as, for instance, where his ground of complaint is that they have been under-rated.

The overseers who in some parishes acted under the direction of a select vestry, and are assisted by assistant overseers, were to apply the poor-rate to the relief of the poor of their parish. The poor of the parish are, in one sense, all those who happen to be in the parish at the time of their being in distress: for the parish in which they happen to be is bound to afford such paupers immediate, or, as it is called, casual relief. The 13 & 14 Car. II. c. 12, is the foundation of the present law of settlement, which determines the parish to which a pauper belongs, and gives the power of removing him to it. This law is called the law of settlement. The statute enables two justices, upon complaint made by the churchwardens or overseers of the poor of any parish, to any justice of the peace, within forty days after a person coming to settle there, in any tenement under the yearly value of 10*l.*, by their warrant to remove such person to the parish where he was "last legally settled, either as a native, householder, sojourner, apprentice, or servant, for the space of forty days at the least." Later statutes have greatly modified the heads of settlement here enumerated, and have added others; they have also made a pauper irremovable, until he has become chargeable to the foreign parish by receiving relief from it, either in person or through the hands of his wife or children.

The following are the settlements that subsisted at the passing of the Poor-Law Amendment Act:—settlement by birth, parentage, marriage, hiring and service, apprenticeship, renting a tenement, estate, office, payment of rates. Settlements may be divided into two general classes; being, first, natural or derivative settlements, as by birth, parentage, or marriage, to the perfection of which residence in the parish is unnecessary; secondly, acquired settlements, including all the remaining settlements above mentioned, and to these residence for forty days in the parish is necessary. The following were the modes of acquiring the various settlements which have been enumerated:—1, settlement by birth.—In order that children may not be separated from their parents, the settlement of the father during his life, and the settlement of the mother after his death, is the settlement of the children. But legitimate children who have no known settlement are settled in the place of their birth; so also are illegitimate children, for they can derive neither settlement nor anything else from their parents. Children, however, during the age of nurture, which continues till they are seven years of age, must not be separated from their parents, and are therefore to be supported in the parish where their parents happen to be, at the expense of the parish of their birth settlement. 2. Settlement by parentage.—The settlement of the father, or, if he have none, the maiden settlement of the mother, is communicated to legitimate unemancipated children. After the father's death their settlement shifts with that of the widow, until she marry again, in which case the settlement of her new husband is not communicated to them. A child is said to be unemancipated so long as he forms part of the parent's family. A child is emancipated when he gains a settlement of his own, or, being of the age of twenty-one, lives apart from and independently of the parent, or contracts some relation inconsistent with his continuing a subordinate member of the parent's family, as by marrying or enlisting as a soldier. Any settlement of the parent acquired after the child's emancipation is not communicated to him. 3. Settlement by marriage.—To prevent the separation of husband and wife, the settlement of the husband is communicated to the wife; she can acquire no settlement during marriage; and, if he have no settlement, she cannot be separated from him by removal to her maiden settlement. 4. Settlement by hiring and service is acquired by a person unmarried, and without unemancipated children, hiring himself for a year into service, abiding for a year in the same service, and residing for forty days in any parish within the year, and with a view to the service. A general hiring, that is, a hiring where nothing is said as to the duration of the contract, is considered a hiring for a year. The service for the year need not be wholly under the hiring for a year, it is sufficient if part of the service be under such hiring; the residue may be either under another hiring, or under no hiring at all. The settlement is gained in the parish where the servant last *completes* the residence of forty days—the forty days need not be consecutive days; if the servant reside thirty-nine days in parish A, then forty days in parish B, and finally another day in A, A, where he last completed a residence of forty days, will be the place of his settlement. All the forty days must be within the compass of a single year, but it is sufficient if the residence for any part of the forty days be under the yearly hiring. 5. Settlement by apprenticeship is gained in the parish where a person bound by deed as an apprentice last completes a residence of forty days in his character of apprentice. No service is required, but the apprentice during the necessary period of residence must be under his master's control. 6. Settlement by renting a tenement is acquired by hiring and actually occupying a tenement at the rent of at least 10*l.* a year, payment of rent to that amount, and residence for forty days in the parish where the tenement is. By actual occupation is meant that no part of the tenement must be underlet. 7. Settlement by estate is gained by the possession of any freehold, copyhold, or leasehold property, and residence for forty days in the parish where the estate lies. If the estate come to a party in any way except by purchase, the value of the estate is immaterial; but a purchased estate confers no settlement if the price given was under 30*l.* But a person residing on his estate, whatever may be its value, is by Magna Charta irremoveable from it while so residing, although he may have gained no settlement in respect of it. 8. Settlement by office is gained by executing any public office in a parish, such as the office of constable, sexton, &c., for a year, and residing there forty days. The office need not be of a parochial nature, but it must be at least an annual office. 9. Settlement by payment of rates.—In order to acquire this settlement a person must have been rated to and have paid the public taxes of a parish, in respect of a tenement hired at a rent of 10*l.* a year, and have paid that amount of rent, and resided forty days in the parish of the tenement. This head of settlement therefore includes all the requisites of settlement by renting a tenement, except the requisite of actual occupation.

All persons whatsoever, whether natural born subjects of England and Wales, Scotchmen, Irishmen, or foreigners, may gain a settlement in this country. A chargeable pauper is to be removed to the place where he last acquired a settlement. It is often very difficult to find out the place of such last settlement; this is so more especially in cases of settlement by hiring and service and apprenticeship, where the residence, being unconnected with anything of a fixed nature, as a tenement or office in any particular parish, may be continually shifting, the settlement consequently shifting with it, until the last day of the service or apprenticeship. Paupers who have no settlement must be maintained by the parish in which they happen to be, as casual poor, unless they were born in Scotland or Ireland, or in the islands of Man, Jersey, or Guernsey, in which case they are to be taken under a pass-warrant of two justices to their own country. When a pauper has become chargeable, and it is sought to remove him, he is taken before two justices, who inquire as to his place of settlement, and, if satisfied, upon his examination and such other evidence as may be laid before them, make an order for his removal thither. The parish to which he is removed may dispute its liability by appeal to the quarter-sessions, when the order of removal will be quashed, unless it appear that the pauper is settled in the appellant parish.

The Poor-Law Amendment Act (4 & 5 Wm. IV., c. 76) has made no change in the law respecting the rateability of property or the mode of collecting the rate. The Act does not apply itself to the rate until collected; it then takes up the rate for the purpose of securing a better distribution of it. To this end the administration of relief to the poor throughout England and Wales is subject to the control of three commissioners. Their powers, and the new agency established for the administration of relief under their direction, have been already described. In parishes or unions where there are guardians, relief is to be given solely by such guardians or by their order, unless in cases of urgent distress. In these cases an overseer is bound to give temporary relief in articles of absolute necessity, but not in money, and if he refuse, he may be required to do so by a magistrate's order, disobedience to which is visited by a penalty of 5*l.* In parishes which have no guardians, the management and relief of the poor is still left to overseers. With the exceptions above stated, the task of relieving the poor is wholly withdrawn from overseers, these officers, from ignorant or corrupt motives, having been generally found incompetent to the discharge of so important a duty. They are still however entrusted with the making and collection of the poor-rate, which they are to pay over to those who have the distribution of it. The general discretionary power which magistrates formerly exercised in ordering relief is also withdrawn. But a single magistrate may still order medical relief, when called for by sudden and dangerous illness; and two magistrates may order relief to adult persons, who from age or infirmity are unable to work, without requiring them to reside in the workhouse. Relief to able-bodied persons cannot be given out of the workhouse, unless with the sanction of the commissioners. In substance, the wants of the poor are as amply supplied as before the Act, but the manner of administering relief is so regulated, by subjecting the applicants for it to the discipline of a workhouse and to other restraints, that the condition of a pauper, living upon the parish fund, is depressed, in point of comfort, below that of the labourer. Thus a ready test is applied to distinguish real and pretended destitution, and a powerful incentive to work is held out to all who can find employment.

The means also of obtaining employment are increased by enlarging the market for the poor man's labour. This is the result of a relaxation in the law of settlement, and particularly of settlement by hiring and service. The old law had been found to obstruct the free circulation of labour by confining the poor to their own parishes. The labourer himself, from attachment to old scenes and associates, was often unwilling to engage himself for a year in a strange parish, lest, by acquiring a settlement there, he should incur, at some future time, a permanent separation from home; the farmer, on the other hand, had an equally strong objection to hire a strange labourer on such terms as to burden his parish with a new settler.

By the Poor-Law Amendment Act, a settlement by hiring and service cannot now be acquired; but the Act does not interfere materially with settlements previously acquired. Settlements by office and by apprenticeship in the sea service or to a fisherman can no longer be acquired. Settlement by renting a tenement is clogged with the additional qualification that the occupier must have been assessed to the poor-rate, and paid the same for one year. Settlement by estate, like any other settlement, when once gained, used to endure till it was superseded by some new settlement; but now it is converted to a temporary settlement, and to be retained so long only as the proprietor shall live within ten miles of the estate. Settlements by marriage and by payment of rates are untouched. Settlement by parentage and settlement by birth are both affected to this extent, that illegitimate children born after the passing of the Act are to follow the settlement of the mother until the age of sixteen, or until they acquire a settlement in their own right; but they revert to their birth settlement after sixteen, unless they shall have acquired another in their own right. The effect of this change in the law is that an unmarried woman, whose pregnancy in itself made her chargeable, is no longer hunted from the parish in which she happened to be, in order that the parish may not, by the birth of the child therein, be permanently charged with its maintenance. The old law of settlement was full of legal difficulties and refinements, and the effect of the change in the law has been to relieve parishes from much litigation.

As already mentioned, a great change also has been introduced in the general laws of bastardy. Formerly the putative father was liable for the support of a bastard, on the unsupported oath of the mother that he was the father of it. Before the birth of the child, he might be called upon to give security to provide for the child, and, if unable to give such security, might be committed to prison; and, after its birth, an order of filiation might be made upon him by two justices out of sessions. By the new Act neither the mother nor the putative father of a bastard can be punished, as was formerly the case. Female incontinence is checked by making the mother liable to maintain her child in the first instance; and, as already observed, she is left to seek her own remedy against the father of her child, without the intervention of the poor-law authorities.

Any person who marries a woman having children, whether legitimate or illegitimate, is made liable to maintain them until they attain the age of sixteen, or until the death of the mother.

POOR LAWS, SCOTLAND. The foundation of the Old Poor Law of Scotland was the Act of Parliament 1579, c. 74, which in so many respects resembled the celebrated English statute of the 14th of Elizabeth, passed a few years earlier, as to have been considered a mere adaptation from it. The Scotch Act, however, fell short of the English in the one important particular of not providing for the care of the able-bodied. By this old Act, a settlement was acquired by birth, and once so established could not be changed unless by a seven years' industrial residence in another parish. By the Act of 1672, c. 18, this period was shortened to three years. The method of administering the law, which arose partly out of the terms of the old Acts, partly out of custom, and partly from the directions given to these sanctions by the judgments of the courts, was as follows:—In the rural parishes, the "kirk sessions," or lowest ecclesiastical judicatories, consisting of the parish clergyman and certain elders, shared the management with the "heritors," or rated landed proprietors; but it became customary for the latter body to interest themselves solely in the voting and levying of the rate, leaving its distribution and the management of the poor to the former. In those municipal corporations holding rank as royal burghs, the assessment and management lay with the corporate authorities. The funds for the relief of the poor were of two kinds: the collections at church doors, along with certain fees and eleemosynary bequests, constituted the one department; and rates assessed on the parish, or a substitute voluntarily paid instead of an assessment, the other. Of the sums collected at the church doors, only a half went to the regular relief of those legally entitled to relief; the other became a fund for general charitable purposes at the command of the kirk session. In many cases there was no assessment, and the regular practice came to be, that if the miscellaneous sources were insufficient for the relief of the poor, the heritors and session in a country parish, or the magistrates in a town parish, might levy a rate. It became a common practice for the parties chiefly interested to agree to a "voluntary assessment," for the purpose of postponing the imposition of a fixed legal rate. When an assessment was imposed, it became a rule that one half of it should be levied on the proprietors of land, in respect of their land; the other on householders, in respect of their "means and substance," or their incomes so far as not derived from land. The adjustment of the rating was the ground of much dispute, and different parishes followed very distinct methods in practice.

For a considerable period the Scottish system was very favourably received by political economists, who saw the country in a comparatively sound moral condition, with a parsimonious poor law, while the lavish system of England seemed to promote profligacy and idleness. But from the time when these doctrines were first promulgated to the completion of the great change of the English poor law, a vast internal alteration had taken place in the social economy of Scotland. The comparative low rate of wages, attracting manufacturing capital from England, had caused a more than average migration of the rural labourers to the manufacturing districts, and a peculiarly rapid increase of the city population. It was found that with these complicated materials, the simple parochial system adapted to a state of society where each man watched over the interests and the conduct of his neighbour, was incapable of grappling. It was found that even for poor country districts the system was unsuitable, because, though still far behind the English system in profusion, the administrators were compelled by the voice of public opinion to become more liberal in their dispensations, while the managers of the country parishes not subject to the same influence kept down the allowances, and thus gave the poor an inducement to endeavour to obtain a settlement by three years' industrial residence in the cities. Dr. Chalmers was the great champion of the old system. With the assistance of some enthusiastic followers, he organised the administration of a parish in the poorer parts of Glasgow, as a demonstration of the efficiency of which the system was capable. It was a very pleasing picture, but the public soon felt that the success with which one energetic individual and his enthusiastic followers might voluntarily perform the duties generally exacted by legal compulsion, was no sufficient ground for believing that the rest of the community can be at all times and in all places depended upon for the performance of onerous public services without the coercion of law.

The public were first awakened to the imperfections of the Scottish Poor Law by Dr. W. P. Alison, a physician in Edinburgh, and professor of the practice of medicine in the university. Having frequently administered professional services to the poorer classes, he showed from his own experience that the utter inadequacy of the provision afforded to those who, by inability to work, or bad seasons, or revulsions in trade, were reduced to want, was an extensive cause of disease, vice, and misery. The city population speedily answered to this appeal, and associations were formed, and inquiries made in various directions. It was shown that the amount expended on the relief of the poor in Scotland amounted to little more than a sixth part of the sum distributed throughout an equal population in England by the economised poor law. In England, the expense of supporting the poor amounted to 6s. 10¾d. per head of the population; in Scotland, to 1s. 2¼d. In some of the Highland parishes, whence the most destitute objects emigrated over the rest of the country, the allowances were ludicrously small; and a report made to the General Assembly of the Church of Scotland in 1839, enumerated instances where sums averaging from 3s. to 1s. yearly were solemnly awarded to destitute people, as the provision which the Poor Law made for their wants. In the meantime the discussion of these matters had a tendency gradually to increase the amount of the provision for the poor. The practice of assessments made considerable progress, and a return to parliament in 1843 shows that between 1836 and 1841 the sums raised by assessment had increased from 89,101*l.* to 128,858*l.*; while the sums raised by voluntary assessment had risen from 15,829*l.* to 22,385*l.* A commission was at last appointed to inquire into the whole state of the subject; and after hearing much evidence, they presented a report, accompanied by a voluminous appendix, in 1843. The amendments proposed in this report were supposed to be of a somewhat narrow nature; the country expressed dissatisfaction with them; and in 1845 a measure was passed embodying alterations considerably more extensive.

By this Act, 8 & 9 Vict., c. 83, a board of supervision is appointed, consisting of persons connected with the municipal bodies and the administration of justice in Scotland, with one salaried member, who gives constant personal attendance. The office of the board is in Edinburgh. This board is endowed with ample means for ascertaining, in all parts of the country, the condition of the poor, and the method in which the system of relief is administered. The board has, however, no directory or prohibitory control over the proceedings of the local boards. These bodies are, however, re-organised by the Act. In the rural parishes where there is an assessment, the local board is to consist of landowners to the extent of 20*l.* annual value, the kirk session, and certain elected representatives of the ratepayers, according to the number fixed by the board of supervision. In city parishes, the boards are each to consist of four persons named by the magistrates, deputies not exceeding four from each kirk session in the city, and certain elected persons according to a number and qualification fixed by the board of supervision. In parishes where there is no assessment, the management is to continue under the old system. There is thus in this Act no machinery for levying or exacting a rate for the poor, unless in those parishes where the persons more immediately concerned agree to such a measure. It is held, however, that the facilities which the statute gives the poor for exacting from the respective parochial authorities the relief to which they are entitled, will render it necessary to put more extensive funds at the disposal of the distributors of relief, and this can only be accomplished through the system of assessment. When persons apply for relief, it is provided that, though they have no settlement, if the claim would be just in the case of their having one in the parish where it is made, subsistence must be afforded them till it is determined what parish is liable. When relief is refused, the applicant may apply to the sheriff, who may grant an order for temporary relief, and then hear parties, and decide whether the applicant is or is not entitled to relief. In this form, however, neither the sheriff nor any other judge can decide on the *adequacy* of relief. The initial step to any judicial appeal against the amount of the relief afforded, is by an application to the board of supervision; and on that body reporting its concurrence, the applicant is placed on the poor-roll of the court of session, where he has the privilege of the question being discussed gratis. By this Act, provision is made for medical attendance and medicines, being part of the system of pauper relief, and for the education of pauper children. It is provided, that for the purposes of the Act, parishes may be united into "combinations." By a special clause, nothing in the Act is to be construed as entitling the able-bodied to relief, and their claim is thus left in the state of doubt in which it stood before the passing of the Act. Men deserting their wives and children are made liable to punishment as vagrants, a provision which it is hoped may afford a remedy to a defect which has long characterised the law of Scotland—the absence of any means by which deserted wives can make effectual claim on their husbands for sustenance to themselves and their children, without a regular action in the court of session. By the new Act, a new and more specific mode of apportioning the assessment between landed and other property has been attempted to be established; but this provision is already a fruitful source of dispute and litigation. The time necessary to acquire an industrial settlement is increased from three to five years.

POPE (*Papa*, in Latin) is the title assumed by the bishop of Rome as head of the Roman Catholic Church. The word papa, or papas, meaning "father," is used by the Greeks to denote a presbyter. In the early ages of the church it was given to the bishops in general. (Ducange, 'Glossarium;' Moreri, 'Dictionnaire Historique.') Gregory VII., in a council held at Rome, A.D. 1076, decreed that the title Papa should be given only to the bishop of Rome, as a mark of superior respect.

There are three offices or dignities united in the person of the Roman pontiff. He is—1, the primate or head of the Roman Catholic world; 2, he is bishop of Rome and metropolitan of its province; 3, he is the temporal sovereign of the Papal State. His authority and the manner of his administration in the last-mentioned capacity are described under PAPAL STATES in the GEOG. DIV. We may, however, here add, that in 1860 a very material alteration has taken place in the dominions of the Pope. The far greater part of the territories there mentioned as owning his sovereignty, have transferred their allegiance to Victor Emmanuel of Sardinia, and the power of the Pope is now nearly circumscribed within the Legation of Rome, and the Delegations of Ancona, Viterbo, Orvieto, and Civita Vecchia, and even there it is in effect only maintained by the presence of French troops.

Considered as pontiff and primate of the Roman Catholic church, the pope has a very extensive spiritual authority over the members, both clerical and lay, of that communion. The limits of this authority are however variously defined even by Roman Catholic theologians. We cannot do better than quote on this subject the definition given in a work of considerable repute and written with great discrimination, which is entitled 'Bibliothèque Sacrée, ou Dictionnaire Universel, Historique, Dogmatique, Canonique, Géographique, et Chronologique des Sciences Ecclésiastiques, par les Révérends Pères Richard et Giraud, Dominicains; réimprimé avec additions et corrections par une Société d'Ecclesiastiques,' 20 vols. 8vo, Paris, 1822. Under the head 'Pape,' section iii., 'De la Puissance et Authorité du Pape,' we read as follows:—1. "All Catholics acknowledge that the pope holds by divine right a primacy of honour, of precedence, and of authority and canonical jurisdiction in the whole church, because he is the successor of St. Peter, to whom Jesus Christ granted those privileges. (Matthew x. 2, and xvi. 17-19.) But is the pope infallible in his decisions concerning law or discipline? Is he above the general council? Has he any power, direct or indirect, over sovereigns and kingdoms? Divines are very much divided in opinion upon these questions."

2. "We may consider the pope either as a private and individual doctor of the law, or as the sovereign pontiff speaking 'ex cathedrâ' in his quality of head of the universal church, to which church he proposes something to be believed as an article of divine faith, under pain of heresy, and this he does after having prayed, having consulted the sacred college of cardinals, and employed the other customary means in order to ascertain the truth. Now the French theologians in general, agreeably to the fourth proposition of the Gallican church, maintain, that even in this case, when he speaks 'ex cathedrâ,' the pope is not infallible, and that his decisions become infallible only after they have been accepted by the church, either in council assembled or dispersed in its various congregations throughout the world. The Italian divines on the contrary, commonly assert that the pope is infallible when he speaks 'ex cathedrâ,' independently of the consent of the church. They ground their assertion on the passage in St. Matthew, 'Tu es Petrus,' &c. 'How,' say they, 'can the church be infallible, if the foundation upon which it is built be not infallible? Does the church rest upon Peter, or Peter upon the church?' To this their opponents reply—1, that the rock upon which the church is built means faith, and not the person of Peter; 2, that the promise of infallibility was made to the whole church, and not to Peter individually; 3, that all the passages which are quoted from the Scriptures or the fathers in favour of the infallibility of the pope apply not to the individual who is seated on the chair of St. Peter, but to the chair itself, to the see of Rome, the Roman church, the whole succession of the Roman pontiffs, the universal church in short." The writer of the 'Bibliothèque Sacrée' winds up these conflicting statements by saying, "This question is not one of faith." To this remark however some will object, that the question is considered as one of faith at Rome, for as the Roman (or, as the French call them, the ultramontane) canonists assert the infallibility of the pope by divine right, it follows that they consider the belief in that infallibility, and in all the decisions emanating from it, as matters of faith; and as long as this controversy remains unsettled, a door is always open to schism, as it happened in the council of Basel, and the alleged unity of the Roman Catholic church is only nominal and precarious.

3. "The same theologians who assert the infallibility of the pope, assert also his superiority above the general councils, and that he has the right of dissolving them, transferring them to a different place, of approving or condemning, reforming or abrogating their decisions. Those divines, on the contrary, who maintain that the pope is not infallible, maintain also that he is subject to the general councils both as to faith and discipline. This is the opinion of the French clergy, embodied in the second of the four propositions of the Gallican church, promulgated in 1682, which 'approves the decision of the council of Constance, declaring the councils general to be superior to the pope in spiritual matters.' The assertors of this proposition say that 'the pope is the head of the faithful nearly in the same manner as the general of a monastic order is the head of all the members of that order, to whom however he is subject when they are assembled in a general chapter.' It may be observed here, that besides the council of Constance, which decided this question of the superiority of the general councils over the pope, there is the council of Basel, which asserted the same principle, and that the council of Basel is reckoned by the French theologians among the legitimate councils of the church, but is not so reckoned by the canonists of Rome."

4. "There are some writers who pretend that the pope has by divine right a direct power, both spiritual and temporal, over the whole world. Others maintain that he has at least an indirect power in temporal matters, inasmuch as he can dispose of kingdoms and crowns, and transfer them from one prince to another whenever that is required for the welfare of souls. Lastly, other divines are of opinion that neither the pope nor the church has any power, direct or indirect, in the temporal matters of kingdoms and states, that they cannot in any case depose kings, nor release their subjects from their oath of allegiance. In support of their argument, these divines show that Jesus Christ made open profession of poverty, that he solemnly declared that his kingdom was not of this world, and they allege other passages as equally decisive; and they say that the Saviour bequeathed to the church a purely spiritual authority, to be exercised in preaching, baptising, instructing, and loosening or binding sinners. The early fathers have said that the church has only the spiritual sword to keep its children within the path of duty. The most celebrated universities of Germany, France, and Spain have confirmed this opinion, which is that of the Gallican church and of Bossuet himself. The contrary opinion, namely, that the popes have a temporal jurisdiction over kings and principalities, is not of older date than the time of Gregory VII."

Such are the statements of orthodox Roman Catholics in a work which condemns all heretics and Jansenism: for the Jansenists assert that the pope has no authority over the bishops, but only a superiority of rank; that all the bishops are vicars of Christ, and that the pope is the first among them, and that his jurisdiction is not to confer episcopacy, but only to watch over the conduct of the other bishops, &c. These opinions of the Jansenists are found, among other works, in the 'Acts of the Synod of Pistoia held by De Ricci' ('Atti e Decreti del Concilio Diocesano di Pistoia dell' anno 1786'), which were condemned by Pope Pius VI. As for the Protestant and Reformed churches, they do not acknowledge any authority or jurisdiction in the pope, except over his own diocese as bishop of Rome, or at most over the other dioceses of the province of Rome as metropolitan. The Greek, Armenian, Jacobite, and Nestorian churches likewise disclaim his authority. Several Roman Catholic writers have endeavoured to trace the growth of the supremacy of the Roman see over the churches of the West, which supremacy they assert was once limited to the provinces which constituted, under the Christian emperors, successors of Constantine, the vicariate of Rome, namely, Etruria, the March of Ancona, Valeria, Apulia, Calabria, Lucania, the Abruzzi, Sicily, Sardinia, and Corsica. These provinces were under the lay jurisdiction of an imperial vicar. The rest of Italy, with Rhætia, constituted the vicariate of Italy, of which Milan was the capital. Both vicariates were subject to the prefect of Italy, who had also under his authority the provinces of Africa and Illyria. The provinces which formed part of the vicariate of Rome were called "suburbicariæ," and their dioceses acknowledged the bishop of Rome as their metropolitan. Such is the opinion of Father Sirmond, and of Du Pin, in his 'De antiquâ Ecclesiæ Disciplinâ,' and of Giannone, in his 'Storia civile del Regno di Napoli.' They contend that until the reign of Valentinian III. the metropolitan authority of the bishop of Rome did not extend beyond the suburbicarian provinces. Allatius, Baronius, Maimbourg, and others, on the contrary, contend that the bishop of Rome was by right the metropolitan of the whole West, if not of the whole Roman empire. Gregory I. (the Great), however, disclaimed the title of Œcumenic or universal bishop, and in token of humility assumed that of "Servus Servorum Domini," the "Servant of the Servants of the Lord," which his successors have continued to place at the head of their briefs and decretals.

In his quality of bishop of Rome, the pope delegates his authority as ordinary to a prelate called Vice-Gerente, who is generally a bishop *in partibus*. In his quality of metropolitan of the province of Rome, he has under him the bishops called Suburbicarii of Ostia and Velletri, of Porto and Santa Rufina, of Sabina, of Frascati, of Albano, and of Palestrina. As primate of the Roman Catholic church, he has under him all the cardinals, archbishops, and bishops of the Roman Catholic states; those placed in states professing Reformed doctrines, and those *in partibus*, or having episcopal titles with a nominal see. The total number of people who profess the Roman Catholic religion in Europe is roughly calculated at about 112 millions, or about two-fifths of the population of Europe. The countries of which the established religion is Roman Catholic are—1, Italy; 2, Spain; 3, Portugal; 4, France; 5, Belgium; 6, Bavaria. In South America, the states formed by Spanish and Portuguese settlers are also exclusively Roman Catholic. Roman Catholic congregations are scattered about various countries of Asia, but in small numbers.

For the manner in which the pope carries on the spiritual government of this extensive flock, see CATHOLIC CHURCH and CONCORDAT. The form of election of the pope is given under CONCLAVE. For the history of the most distinguished popes, see their respective names in the BIOG. DIV. The reader may refer also to the 'Vitæ et Res Gestæ Pontificum Romanorum ab Initio nascentis Ecclesiæ usque ad Urbanum VII.,' by Ciaconio, Cabrera, and Vittorello, fol., Rome, 1630. A list of the succession of the popes will be found in Petau's 'Rationarium Temporum.'

POPLAR, ECONOMICAL USES. There are several varieties of poplar tree, which render useful service in the arts. The timber of the *white* poplar is very light coloured, and is used in France and Germany for a variety of minor purposes. It makes excellent packing cases, because nails may be driven into it without causing it to split. It is used extensively by turners and cabinet-makers. The boards and rollers around which pieces of silk are wrapped in merchants' warehouses and in shops are made of this wood, which is adopted on account of its lightness lessening the expense of freight. It is much used for flooring-boards, for large folding-doors for barns, and for other building purposes. It is used as a substitute for lime-tree in musical instruments. Wooden dishes and casks are occasionally made of it. The timber of the *black* poplar is used for much the same purposes as the white. It is yellow, soft, and easy to work; and is preferred by cabinet-makers for many purposes. It is used for clogs, the soles of wooden shoes, bowls and other turner's ware, and in cart-building. The *Lombardy poplar* produces wood less serviceable than that from the other varieties; but rafters, small beams, boards, &c., made of this wood and afterwards coated with tar, are found to be durable. The wood of the *Trembling poplar* or *Aspen* is white and tender; and is employed by turners; by coopers for herring casks, milk pails, &c.; by sculptors and engravers; by joiners and cabinet-makers; and by the makers of clogs, wooden shoes, butchers' trays, pack saddles, and a number of other articles.

As fuel, poplar wood is of inferior heating power; but it gives out its heat very quickly; the ovens belonging to most of the Paris bakers are heated by this wood. The bark of the black poplar is employed in tanning leather; when pulverised it is eaten by sheep; and being very thick, light, and corky, it is used by fishermen to support their nets, and even as corks for bottles. The bark of the aspen forms the principal food of the beaver; it is also usefully employed in medicine.

In Sweden the leaves of the white poplar are eaten by cattle. The buds of the black poplar, macerated in boiling water, and afterwards bruised in a mortar and pressed, yield a fat substance which burns like wax and exhales a fine odour. The balsamic sap with which the buds are covered forms the basis of an ointment that was much prized in former times. The young shoots may be used in basket-making; and the shoots with the leaves on are sometimes used as brooms. The cottony substance or flock that surrounds the seed has been used in Germany and France as wadding; and it has also been occasionally manufactured into cloths, hats, and paper. The *Balsam poplar* yields a balsam from the buds; it is collected from the trees in spring, at which season it collects into drops on the points of the buds. In Siberia a medicated wine is prepared from the buds.

POPLIN. Among the varieties of woven goods in which silk and worsted or silk and woollen are used in combination, poplin is one of the best and most esteemed. *Tabinet* is one form of this material; and Ireland has been distinguished for the excellence of its poplins and tabinets. The demand is now small, as other kinds of textile fabric have lately been more in favour; but the rich Irish poplins and tabinets, though employing only a small number of persons in their manufacture, maintain their high character.

POPULATION [CENSUS.]

POPULIN, *Benzoil-salicin* ($C_{26}H_{17}(C_{14}H_5O_2)O_{16} + 4$ aq.) a peculiar product obtained from the bark and leaves of the poplar (*Populus tremula*). After extracting salicin from them, this remains in the mother water: carbonate of potash being added to it, a white precipitate is obtained, which is to be dissolved in boiling water. On cooling it crystallises in needleform crystals, which have an acrid and also a sweet taste, resembling that of liquorice. It dissolves in 70 parts of boiling water and in 2000 of cold water. Its solution in acids is precipitated by water. To sulphuric acid it imparts a red colour. The crystals contain 5·43 per cent. of water of crystallisation.

PORCELAIN. [POTTERY.]

PORCH (from the Latin *porticus*), a general term for any projection forming a covered space immediately before the entrance to a building, open in front, and more or less enclosed at its sides. The distinction between a porch and a portico is, that, however important it may be as a feature, the porch appears only a subordinate part of the building to which it is attached; whereas the portico [PORTICO] may be the whole of a front: therefore, though the term porch is usually employed only in speaking of the Romanesque and Gothic styles, it would be more correct and convenient to apply it, without regard to style, to what bears the character of a porch. By attending to such distinction, misconception would sometimes be prevented: for instance, if the Athenæum Club-house, London, were described as having a Doric portico, any one unacquainted with the design would imagine that the order was carried up as high as the general entablature of the building; whereas by terming it a Doric porch, such misconception would be avoided.

As far as we are aware, the only instance of a porch in Greek architecture is that in the octagonal structure called the Tower of the Winds, or that of Andronicus Cyrrhestes, which has a small prostyle portal on two of its faces, north-east and north-west, each consisting of a simple distyle, or two columns and their entablature, surmounted by a pediment; and which therefore may be regarded as the prototype of those ornamental compositions for doors and windows, so greatly affected in Italian architecture, which present a *microstyle* application of the orders, that is, small columns adapted not to the entire structure, but to subordinate parts of it.

When portico fronts were laid aside, as partaking too much of the previous Pagan temple; when columns began to be not only attached to the building, but employed as microstyle decorations to its different external stages or stories, often very irregularly, and generally connected together by arches; in short, when the Roman style was transformed into and superseded by the Byzantine and the Romanesque styles, porches began to be important features, subordinate indeed in size to the structures to which they were attached, but principal in regard to embellishment, being frequently composed of groups of small columns, elaborately wrought, and some of them often placed on the backs of lions or other animals, and supporting a series of concentric arches or archivolt mouldings equally enriched. Here microstyle embellishment may be said to have been carried to such a height as to be ultimately lost sight of: the columns became at length mere subsidiary members, and a combination of vertical mouldings or shafts cut out of the receding angles constituted the general splay of the whole portal, which was thus extended in appearance ad libitum, without regard to the size of the actual doorway or aperture itself, a very important advantage as regards design.

In the Norman-Gothic style, the porches or portals are little more than a modification of the similar features in Romanesque architecture. Of porches however strictly so called, that is, portals projecting out from the edifice, so as to form a sheltered external vestibule, we have comparatively few Norman instances, and those do not occur in the principal front, but at the sides of buildings. The same also is the case in Pointed Gothic architecture, where, though we often meet with spacious and magnificent portals, especially in continental examples, we do not find advanced porches brought out beyond the general plan of the building in front; the porch being there almost invariably enclosed within the lower part of the structure, even where it may be said to project with respect to that part of the front which is seen above it, but on a different plane, as for instance in the front of Westminster Hall, Winchester Cathedral, &c., although in those cases the entrances are placed rather within deep recesses than porches. In church architecture, entrances of the last mentioned kind hardly ever occur at the west end or front, but were frequently made very conspicuous features in the side elevations, of which we have striking instances in the beautiful north porches at Salisbury and Wells cathedrals, both of which advance out very considerably. Some of the porches in our larger parish churches have a room above. [PARVISE.] Wooden porches are common in the smaller churches of every period of English pointed Gothic architecture.

In our ancient domestic architecture the porch, where it occurs at all, forms a marked, though not always a central feature, in the principal front. When it projects from the main structure, it is usually carried up so as to have a room, or else what forms a bay in a room, over it; and it is not unfrequently carried up higher than the rest, so as to form a kind of tower; or else the porch is recessed within the building, and presents externally merely an open arch. In many Elizabethan buildings, the porch, though forming a narrow compartment of the whole front, is profusely ornamented, even where the rest is quite plain. Kirby, in Northamptonshire, the seat of Lord-Chancellor Hatton, offers a most elaborate, not to say extravagant, example of the kind.

PORISM (*πόρισμα*). An intermediate class of propositions, between problems and theorems, was, as we are informed by Pappus, distinguished by the ancient geometers under the name of porisms. Unfortunately, however, the only notices of them by the ancients themselves, which are found in their remaining works, occur in the 'Collectiones Mathematicæ' of Pappus Alexandrinus, and the commentaries of Proclus on the Elements of Euclid, in both places so very imperfectly, that till of late years mathematicians were not agreed on their exact interpretation. The description of porisms by Pappus, which he gives in the preface to the seventh book of his above-mentioned work, in an account of Euclid's work on the subject, is, in all the manuscripts which have been examined, extremely mutilated, and every attempt to restore them, before the masterly hand of Robert Simson took up the subject, had completely failed. The first part of the description, which seems to be entire, is calculated only to excite curiosity, being too general for conveying any precise notion of these propositions, or for giving any effectual assistance for the recovery of them; and the remainder, containing a detail of the contents of Euclid's work, is through the whole so corrupt that all endeavours to explain it were nugatory. Several celebrated geometers indeed flattered themselves that they had obtained possession of the secret; but even Dr. Halley, with all his acuteness, relinquished the task, and adds, after giving the original, "hactenus porismatum descriptio nec mihi intellecta nec lectori profutura." The definition which Pappus quotes from the ancients is too general to be useful, and perhaps implied more than our acquaintance with the language in which he wrote can enable us to determine. He says that a "theorem is something requiring demonstration, a problem in which something is proposed to be constructed; but a porism, that which requires investigation;" and though this definition certainly does correspond to the nature of these propositions, yet it is deficient in discrimination, and of itself neither conveys any precise notion of Euclid's porisms, nor gives assistance in the investigation of any individual proposition. Dr. Simson's restored definition is as follows, literally translated :—"A porism is a proposition in which it is proposed to demonstrate that some one thing or more things are given, to which, as also to each of innumerable other things not given, but which have the same relation to those which are given, it is to be shown that there belongs some common affection described in the proposition." The following less literal translation may probably be better understood :—"A porism is a proposition in which it is proposed to demonstrate that one or more things are given, between which and every one of innumerable other things not given, *but assumed according to a given law*, a certain relation described in the proposition is to be shown to take place." Dr. Simson illustrates the propriety and accuracy of this definition by many examples, and it is so framed as to correspond with all the intimations of Pappus respecting porisms, and also with the character of the few individual porisms of Euclid which Dr. Simson had discovered. It may therefore justly be considered as expressive of the notions on this subject entertained by the ancients, although probably, as in the cases of theorem and problem, no precise definition was given of porism. It has been objected to Simson's definition, that it may be inferred from it that a porism partakes more of the nature of a problem than a theorem, and consequently is inconsistent with the "intermediate nature" mentioned by Pappus. In his enunciation it is affirmed that certain things *may* be found which shall have the relations or properties therein described. Now were it simply proposed to investigate certain things which would have the properties expressed in the porism, it may be regarded as a problem; but if these things are found by a construction described in the enunciation, the proposition becomes a theorem affirming the truth of the properties asserted; and then a demonstration only is required, without any investigation, in the manner which appears to have been practised by the later mathematicians alluded to by Pappus. The enunciation of a porism as a problem is not consistent with the usual character of such propositions. Problems usually, whatever difficulty may attend their solution, are almost immediately recognised, by those having some knowledge of geometry, as either possible in certain circumstances of the data, or as altogether impossible; and it would be unusual to propose as a problem "to find things with certain properties, respecting the possibility of which no judgment can be formed without an analysis, or such consideration as is equivalent to an analysis." For example, if it had been proposed as a problem in the time of Apollonius, to find in a given parabola a point having the property of the focus, that point being then unknown, such a proposition would not have been considered as a proper problem, but would in reality have been a porism. To take another example :—Proclus, in his commentaries on the Elements, mentions the first proposition of the third book, "to find the centre of a circle," as a porism, being in some measure between a problem and a theorem. But Proclus, however distinguished as a philosopher, was no mathematician, and as a circle, from Euclid's definition of it, must have a centre, the proposition to find that centre seems to be a proper problem. Had the circle been defined from another of its properties, as, for instance, from its being produced by the extremity of a straight line moving at right angles to another straight line, given in magnitude and position, and in the same plane, so that the square of the moving line be always equal to the rectangle by the segments into which it divides the given line; then the finding of the centre would be a proper porism, and might be enunciated thus :—"within a given circle (defined in the manner just mentioned) a point may be found from which all straight lines drawn to the circumference will be equal."

Having thus placed before our readers the most probable restoration of the ancient meaning of the term porism, we proceed to notice briefly what modern geometers have given us on the subject. First in importance stands the admirable paper on porisms by Professor Playfair, in the first volume of the 'Transactions of the Royal Society of Edinburgh,' which was read before that body in July, 1784. He improves on Simson's definition, and substitutes the following :—"A porism is a proposition affirming the possibility of finding such conditions as will render a certain problem indeterminate, or capable of innumerable solutions." This, it must be confessed, is an important and elegant simplification, and fully conveys every idea contained in the more prolix definition of Simson; but at the same time we agree with Dr. Trail in thinking that Dr. Simson's is expressed more nearly in the language and manner of the ancient geometers :—"Though I admire the ingenuity and fully admit the soundness of this definition, and also the utility of the principle on which it is founded in the discovery of porisms, I must acknowledge my doubt of that particular notion of a porism having ever been adopted, or even proposed, among the ancient geometricians." (Trail's 'Life of Simson,' pp. 50, 51.) A paper on porisms, containing some examples in the higher geometry, by Lord Brougham, was inserted in the 'Philosophical Transactions of the Royal Society,' in 1798. Fryer has given a popular history of the discovery of porisms, in the last edition of Simson's Geometry. Lastly, the most complete exposition of them that has yet appeared may be found in the 'Aperçu Historique sur l'Origine et le Développement des Méthodes en Géométrie,' 4to, Brus., 1837, by M. Chasles, of the French Institute: as well as in his recently published work, 'Les trois livres de Porismes d'Euclide, rétablies pour la première fois,' Paris, 1860, 8vo.

Porism was also used by the Greek geometers to denote a corollary to a proposition, and the frequent use of the word in this sense, as well as in the other, by Pappus and Proclus, has occasioned much confusion. Proclus says that "corollary is one of the geometrical appellations, but it has a twofold signification," and he proceeds to describe, in a very obscure manner, the difference between the two meanings of the term.

(See *Proclus in Euclidem*, edit. Hervagii, fol. Basil., 1533, fol. 18. We refer the reader also to Henry Savile's *Prælectiones in Euclidem*, 4to, Oxon, 1621, p. 18; and Trail's *Life of Simson*, p. 92.)

POROSITY is that condition of material bodies which consists in the discontinuity of their molecules, the intervals between these being called pores (from *πόρος*, a passage). Porosity is a property common to all bodies in nature, at least we know none in which the particles are contiguous to one another. By pores however we do not mean the *cavities* as in sponge and cork, which are visible to the eye, and scarcely those of other bodies which may be rendered so by the aid of a microscope. In bodies whose pores are not manifest, the existence of the intervals between the molecules is proved by various circumstances. Thus many of the metals become more compact by hammering, and all of them contract in bulk by a reduction of temperature. We may also refer to the Florentine experiment, for determining whether or not water is compressible,—the fluid was by pressure forced through the pores of the vessel of gold in which it was contained. Again, the porosity of bodies is inferred from their elasticity and the sounds which are heard when the molecules are in a state of vibration: also, in transparent bodies it is inferred from the fact that the particles of light pass through them, or that the vibrations of an ætherial fluid take place among the molecules.

When salt is dissolved in water, the particles of the salt seem to introduce themselves between those of the water, so that the volume of the mixture is less than the sum of the volumes of the separate substances; and the like may be said of the mixture of alcohol with water; in which cases the particles of one of the kinds of substance appear to enter and occupy the spaces between the particles of the other. The intervals between the particles of gaseous substances are very great; and though, in some cases, the volume of a mixture is equal to the sum of the volumes of the separate gases, yet, in others, it is equal to not more than $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, or $\frac{1}{5}$ of the sum of the separate volumes. A body of aqueous vapour composed of a volume represented by 2v of hydrogen gas, and a volume v of oxygen gas, is equal in volume to 2v only.

All material substances being subject to attractive forces, it has been made a question whether the attractions which take place between the molecules of bodies, and which are insensible at all appreciable distances from them, are the same as that general attraction which extends indefinitely through space; modified, however, by the figures and mutual distances of the molecules, by heat, electricity, and perhaps by powers which are at present unknown to us; but, in order that this hypothesis may be admissible, the dimensions of the molecules of bodies should be extremely small compared with those of the spaces among them; and the densities of the molecules immensely greater than the densities of the bodies themselves. La Place estimates ('Système du Monde,' ch. xviii. 4th edit.) that a molecule of a spherical form, whose diameter is one millionth part of a mètre, ought to have a density more than six million times as great as the mean density of the earth in order that it might exercise an attraction equal to that of terrestrial gravity; and he observes, that the attractive forces exercised by the molecules of bodies, which are probably only the excesses of the entire attractions of the molecules over the repulsive forces of the caloric in the intervals, must be vastly greater than that of gravity, since the actions of the molecules of a body produce visible inflexions of the rays of light, which cannot be asserted concerning the attraction of gravity. [Attraction.]

PORPHYRIC ACID. [Euxanthic Acid.]

PORPHYROXINE. [Opium, Alkaloids of.]

PORRIGO, *Ringworm*, is a pustular and contagious disease of the scalp, or, in some rare cases, of other parts where there is much hair. M. Biett describes two varieties of it under the names of *P. favosa* and *P. scutulata*. Dr. Willan described many more varieties, but he included in this name other widely different diseases.

Porrigo favosa consists of an eruption of small flat yellow pustules, with depressions at their centres, distinct or clustered, and which soon concrete into bright yellow honey-coloured scabs, on the surface of which the depressions of the centres of each pustule are usually still visible. After some time the scabs become thick and white; and drying, split and break off. Sometimes, however, they remain long adherent, the skin beneath them ulcerating, and the discharge oozing through them. The hair of the parts affected is always much loosened, and often falls off spontaneously; and, when it grows again, is weaker and lighter in colour than before.

Porrigo favosa appears rarely in any part except the scalp. It affects persons of all ages; but especially children from six to ten years old, and those who are naturally unhealthy, or ill-fed and dirty. It is distinctly communicable by contagion, and by this means may affect alike the weak and the robust.

It is one of the most obstinate diseases of the skin, and often lasts for months or years. The first measure for its cure is to cleanse the head completely with poultices or soap and water, and to have the hair cut very close. The dead hair and scabs must then be cleaned off as fast as they form. The medicines that promise the speediest success are lotions with sulphuret of potash or slightly acidulated, or with alkalies or their carbonates, such as in the following forms:—ten grains of potassa fusa in an ounce of water, to be applied occasionally; one or two drachms of subcarbonate of potash in a pint of water, to be constantly applied on linen; or from one to three drachms of sulphuret of potash to a pint of water; or from ten to twenty drops of any of the mineral acids to a pint of water, also to be constantly applied. Lotions also of sulphate of copper, nitrate of silver, and of nearly all the stimulant and astringent salts, have been employed, and sometimes with success; and in most cases of the disease, all these will have to be tried in turn, till one, being found beneficial, is continued till the cure is completed, or till it has ceased to do good, when it must be changed for another. Internal medicines must be employed if there be any symptoms indicating their necessity; but generally they are useless.

Porrigo scutulata, which is more commonly termed *ringworm* than the preceding, appears in the form of circular red patches, with numerous minute yellow pustules with depressed centres, out of which a hair usually projects, and which are attended by great itching. The fluid contained in the pustules dries up soon after they are formed, and, by coalescing, they produce a scab over the whole diseased surface. Subsequently successive crops of new pustules form around the margin of the scab, which is increased by their drying, and thus the disease may spread over the greater part of the scalp by the meeting and coalescing of the patches, which were at first isolated. The hair usually falls off from the part affected, or is so loosened that it may be pulled out without pain.

This form of porrigo sometimes appears spontaneously in poor and dirty children, but it is usually produced by contagion. The suggestions for its treatment must be the same as for Porrigo favosa.

PORT (Wine). [Wine.]

PORTCULLIS, in fortification, is a barrier formed of several large pieces of wood, joined across one another like a harrow, and each pointed with iron at the bottom. A portcullis was generally hung over the gateways of old fortified towns, ready to let down in case of a surprise, when the gates could not be shut. (James's 'Military Dictionary.') The French, at a very early period, called it "porte-coulant," that is, sliding gate, which is the true etymology of the word. "Coulisse" is likewise used by the French writers for the portcullis, whence our term is immediately derived.

PORTER. [Brewing.]

PORTFIRE is a composition consisting of saltpetre, sulphur, and mealed gunpowder, mixed together by being rubbed between the hands, and, after being passed through hair-sieves, moistened with spirits of wine: the mixture is then rammed or driven into a paper case of a cylindrical or conical form, and less than an inch in diameter. A piece of portfire sixteen inches long will burn from twelve to fifteen minutes.

It is generally used as a match for firing artillery, in which case the saltpetre, sulphur, and powder are in the proportion of 6, 2, and 1, respectively; but it is frequently employed in firing mines or in blasting rocks, when the proportions of the like ingredients are as 7, 2, and 8, respectively. For these last purposes the portfire is attached at the extremity of the train, or is inserted in the shaft bored in the rock or object to be blasted; and the fire is applied to it by a match.

PORTICO. Originally applied without distinction to colonnades and covered ambulatories, the term is now limited to signify a sheltered space enclosed by columns at the entrance to a building; and unless otherwise expressed, roofed with a pediment, like the end or front of a Grecian temple. The term therefore, as now generally restricted, answers to the *Pronaos* of such a temple.

According to the number of columns in front, porticos are said to be *tetrastyle*, that is, with four columns; *hexastyle*, with six; *octastyle*, with eight; *decastyle*, with ten; and *dodecastyle*, with twelve, the greatest number that can very well be brought beneath a pediment; and even of these two last the examples are exceedingly rare. If instead of columns at the angles there are antæ [Antæ], then the number of columns alone are reckoned as before, and denominates what is equivalent to a portico containing two more: thus a *distyle in antis*, that is, two columns between two antæ, is equal to a tetrastyle, as in both there are three intercolumns; a *tetrastyle in antis* is equal to a hexastyle, and so on. By means of this simple mode of numerical notation, a couple of words suffice to explain in the concisest manner what even a long description may leave doubtful: for instance, when we say that a portico is hexastyle Ionic, we clearly specify the order, and the number of columns in front; and it is upon this latter circumstance that so much of particular character depends. By way of example, we instance the following structures: distyle in antis, the church in North Audley Street; the entrance to the North-Western Railway Terminus, Euston Square, is a magnificent example of a distyle in antis, though not being an entrance attached to a building, it is rather a propylæum than a portico. Tetrastyle, portico of Hanover Chapel, Regent Street; tetrastyle in antis, Law Institution. Hexastyle, the porticos of St. Martin's; St. George's, Hanover Square; St. Pancras; Post Office; Italian Opera House, Covent Garden. Octastyle, portico of Royal Exchange; British Museum; the National Gallery; and decastyle, that of London University College.

Porticos are called *prostyle* when, as generally happens, they project from the main building. Such as are *in antis*, and recessed within the front of the building, are technically called *loggias*; the latter term indeed is not always employed in this particular sense, but it would be convenient if it were, as much ambiguity would thereby be prevented. The New Town Hall, Leeds, has a decastyle loggia. Although, too, a loggia so far resembles any other colonnade, it differs from it in being situated, like a portico, at the entrance and in the centre of a façade, whereas colonnades are usually lengthened ranges of columns in other situations; thus we speak of the "colonnades" of the Louvre, of Greenwich Hospital, and of the piazza of St. Peter's at Rome.

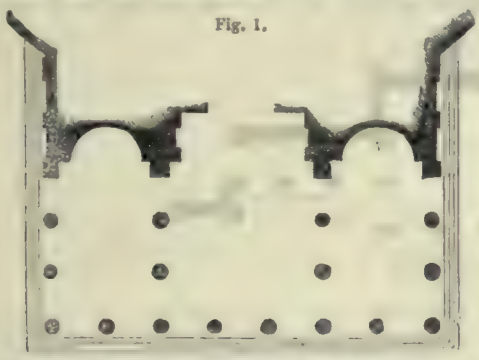
Pseudo-prostyle is a useful term suggested by Mr. Hosking for such an arrangement of columns beneath a pediment as resembles a prostyle in elevation, but which, instead of advancing forwards, forms merely a slightly projecting break, the portico itself being within the building, and nowise differing from a recessed loggia, except that it is not *in antis*, and is crowned by a pediment. Of this kind is the Ionic portico of the East India House, which, instead of being a tetrastyle *in antis*, is converted into a hexastyle by placing six columns in such manner that the end ones come immediately before the antæ or pilasters. The front of the Law Institution, Chancery Lane, may also be called pseudo-prostyle, because, although a loggia *in antis*, it is surmounted by a pediment.

Even in prostyle porticos there is great difference of character merely as regards the degree of projection given to them, independently of other circumstances; some are made to advance a single intercolumn, and others project considerably more. At the risk therefore of appearing to innovate upon the terminology of architecture, we would propose the following terms:—*monoprostyle*, where the portico projects only one intercolumn, as the Ionic hexastyle of St. Pancras church, London; *diprostyle*, where the projection is two intercolumns, as in the porticos of St. Martin's, Charing Cross, and St. George's, Bloomsbury, and so on; by which method the portico of the Pantheon at Rome might be briefly yet distinctly described as a Corinthian octastyle *triprostyle*, that is, a prostyle with eight columns or seven intercolumns in front, and three open intercolumns at its ends. Another circumstance, which it is highly important to note, is whether a portico be a simple prostylo, or be likewise *polystyle*, that is, whether the columns be merely external, or whether there are additional columns within the portico, as is the case with that of the Pantheon, which may therefore be further described as polystylar. The portico of the Kazan church, St. Petersburg, and those of the Glyptotheca at Munich, and Canova's church at Possagno, of which plans are given below, are also polystyle.

Some porticos again may be termed compound prostyles, because, while they project from the building, they also recede within it, as is the case with those of the London Post Office, University College, and Hanover Chapel, Regent Street; and such an arrangement gives greater effect as well as spaciousness, and prevents the portico from looking like a mere addition to the front of a building. Besides the varieties above enumerated, there are those which are semicircular in plan, of which the transept entrances of St. Paul's furnish very admirable examples; and another occurs in the pseudo-portico or portico-like compartment at the north-west angle of the Bank of England (*fig.* 10), which, owing to its being likewise recessed, and having columns behind those in front (not arranged concentrically, but placed on the chord to the outer curve), produces a rich and picturesque effect. Beautiful however as the semicircular form is, it becomes unsuitable for such purpose if a portico so shaped cannot be made equal to a hexastyle, or a tetrastyle in antis, that is, have five intercolumns, because if there be only three, either the whole portico must be very narrow in proportion to its height, or the intercolumns so wide that the architrave over them will considerably overhang a line drawn from one column to another, and thereby produce an appearance both of deformity and weakness.

Respecting the temple-porticos of the ancients, or rather the external arrangement of columns in such edifices, whether confined to the ends or continued along the sides, we refer to the article TEMPLE, where they will be found sufficiently explained; and shall now briefly pass in review some of the porticos that most deserve notice on account of their *plan*, to which we shall confine our attention, passing over all other circumstances. We shall not therefore attend to the order of columns employed in them, nor take any account of their dimensions, the plans being drawn not to the same scale, but for convenience sake, nearly to the same size. We commence with that of the Pantheon at Rome (*fig.* 1), attached to a circular edifice, and which, as will instantly be seen, is decidedly different from the usual portico at the end or front of a temple, or from those monoprostyles, or single external line of columns, which constitute the generality of modern porticos.

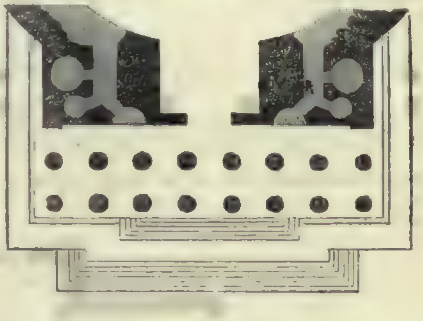
Fig. 1.



Besides being triprostyle, or having three open intercolumns on its flanks, it may be described as polystyle, having columns within, dividing it into three avenues or aisles, the centre one of which is extended by being considerably recessed, a circumstance that adds very greatly to the general effect.

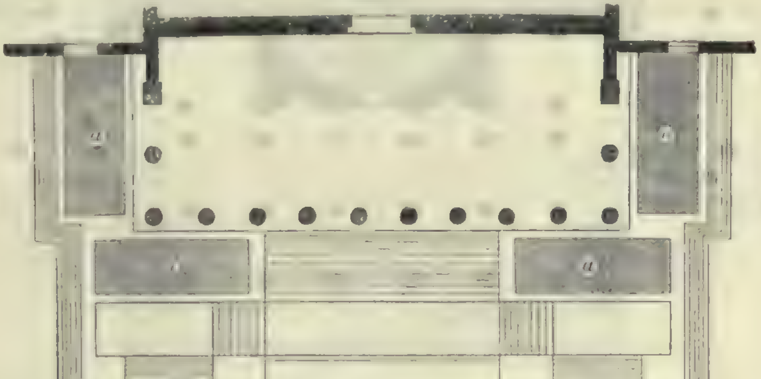
As being, like the preceding, attached to a rotunda, we have selected for the next plan that of the church erected by Canova at Possagno (*fig.* 2). This also is a polystyle, though altogether different in its arrangement from the other, there being here merely a second range of columns behind those in front, on which account it might be designated a double octastyle.

Fig. 2.



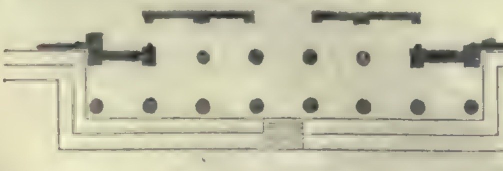
As an example of a decastyle portico, we give that of University College (*fig.* 3), which instead of being merely monoprostyle, or single line of twelve columns, beneath a pediment, projects forwards very considerably, it being equal to a triprostyle, or a pseudo-triprostyle, with one intercolumn closed up, owing to which it appears internally to be partly recessed, to be carried out two intercolumns, and inwards for the space of one. This example is further remarkable on account of the unusual and picturesque arrangement of the steps forming the ascent up to it, which commence below on each side, while above they form a single broad flight, in such manner as to leave screened areas, *a a*, which serve to admit light to the spaces in the basement beneath the portico.

Fig. 3.



The portico of the Glyptotheca at Munich (*fig.* 4) may be described as monoprostyle, recessed, and polystyle, it being compounded of an octastyle advanced only one intercolumn before the rest of the front, and of a tetrastyle in antis behind it, forming five open intercolumns, the extent of the recessed part, by which means not only great richness of columniation, but a picturesque play and contrast are obtained.

Fig. 4.



Like that of University College, the portico of the National Gallery (*fig.* 5) is pseudo-triprostyle, consequently projects as much as three intercolumns from the building; but, in other respects, differs very materially from it, being only partially recessed in the centre, where are two columns forming a distyle in antis. It also differs from the other example altogether in the arrangement of the steps leading up to it.

The portico of the Pantheon at Paris (*Fig.* 6) offers a more singular than judicious arrangement, two columns being projected at each end so as to produce a group of three at the external angles, which, although by no means displeasing in the ground-plan, produces an awkward effect in the structure itself or an elevation of it; because, instead of being included beneath the pediment, these columns and their entablature form mere little jutting-out bits, attached to the flanks, and almost suggest the idea of its being originally intended to continue them as lateral colonnades parallel to the hexastyle beneath the pediment (as in the next figure). Though this portico is only hexastyle in front, and has only four columns within, there are eighteen columns altogether, besides the half and three-quarter columns attached to the wall behind, a number sufficient to have formed an octastyle triprostyle with six inner columns, namely, four disposed as in the portico of the Pantheon (*Fig.* 1), and two forming a pronaos recess for the centre doorway, as in *Fig.* 5.

Fig. 5.

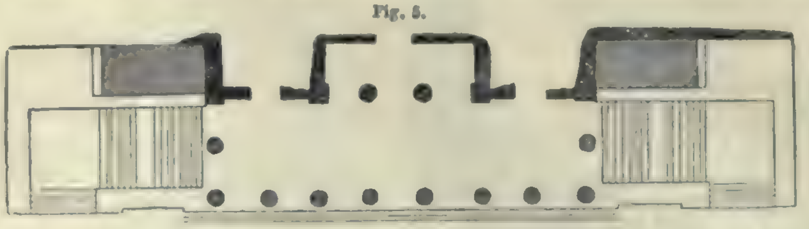


Fig. 6.

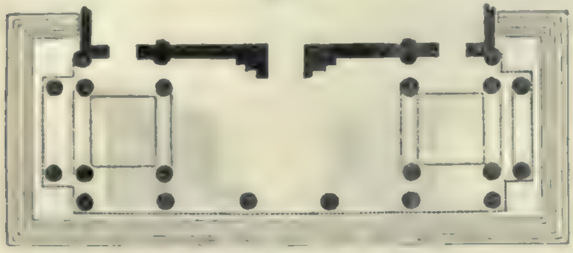

Our next example, which is the portico of the Fitzwilliam Museum at Cambridge (*Fig.* 7), differs materially from the foregoing one, presenting a richer system of columniation in some respects; for though, technically speaking, no more than a monoprostyle octastyle, it is extended by lateral loggias, three intercolumns in width, and has besides considerable depth within.

Although only a hexastyle, the portico of the Kazan Cathedral, St. Petersburg, towards the Nevsky Prospect, is an unusually rich example of a polystyle prostyle, and of certain peculiarities of arrangement which will be better understood from the plan itself (*Fig.* 8) than from any verbal explanation. The cut also shows a portion of the sweeping colonnades (in imitation of those by Bernini in the Piazza di San Pietro at Rome), and the mode in which they are connected, or rather not connected with, but merely brought up to the portico itself, which is so awkward and disagreeable as materially to detract from the effect of the whole.

Fig. 7.

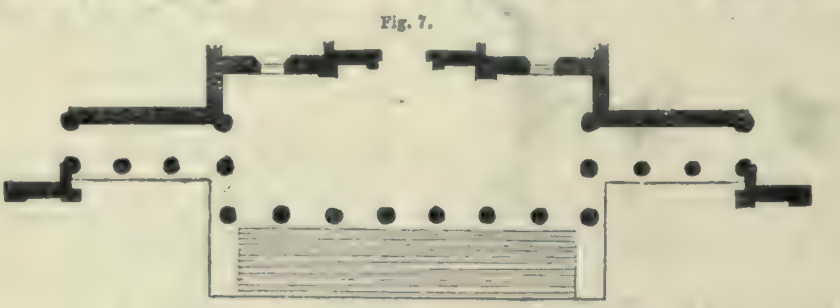

Fig. 8.

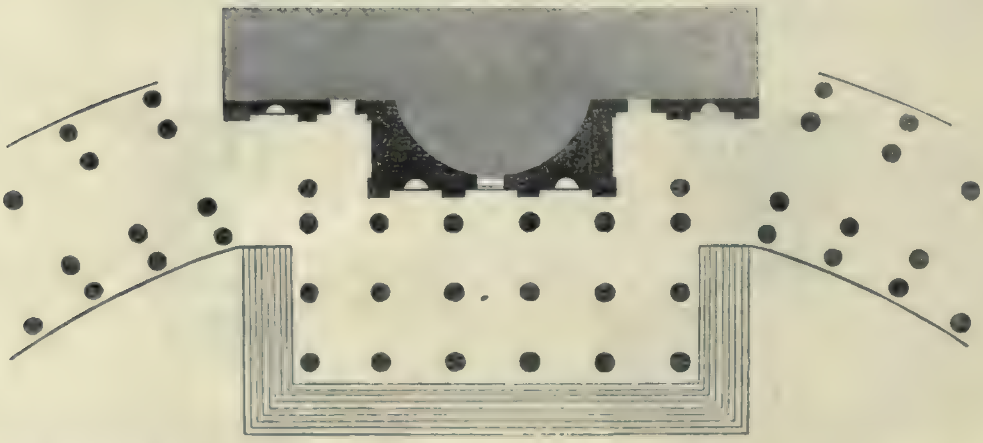

Fig. 9.

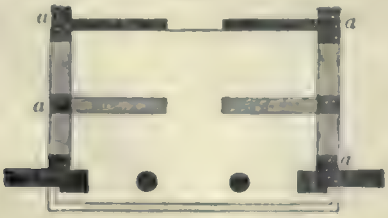
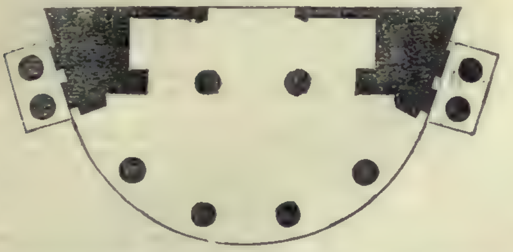


Mr. Gandy Deering's small Doric distyle in antis, in the front of the building originally erected for the Pimlico Proprietary School in Ebury Street (*Fig.* 9), affords an example of a portico with an inner screen carried up half way behind the columns, and with lateral openings at the ends of the portico between small antæ, *a*, *a*, &c., descending as low as the top of the screen, and two of them resting on its exterior ends. The idea is a valuable one, and admits of almost endless diversity and new combinations.

The only other example we shall offer is that of the semicircular, or rather segmental loggia, forming the north-west angle of the Bank of England (*Fig.* 10), the most tasteful and picturesque piece of design that Sir J. Soane ever produced. The effect of the inner columns, the contrast they afford to the others, their shafts being plain, while the rest are all fluted, the varied perspective appearance accordingly as the spectator shifts his station, and the great play of light and shade, all render this little bit quite an architectural study.

Fig. 10.



PORTRAIT (*Portrait*, French; *Ritratto*, Italian; *Bildniss*, German; *Imago*, Latin; *εἰκών*, Greek). A portrait, strictly speaking, signifies the likeness of anything whatever, whether animate or inanimate, either drawn or coloured upon a flat surface: in a more restricted sense it signifies a drawing or a painting representing the likeness of any particular individual; but it is also frequently applied to the pictures of animals.

Portrait, says Lord Orford, is the only true historical painting. Its uses are manifest; it administers to the affections, it preserves to the world the features of those who, for their services, have merited the gratitude of mankind, and of those who have been in any way remarkable for their own actions or through their position in society; and in a simply historical point of view, it illustrates the costume and habits of past ages. In all or nearly all these respects photographic portraiture is of almost inestimable value; but our immediate subject is portrait painting, and to that we must confine our attention. We may, however, remark that it is only by a studious regard to the principles which lead to excellence in portrait painting, that satisfactory results can be obtained in photographic portraiture.

Portraiture seems to be almost as ancient as the art of painting itself; indeed, according to the romantic legend told by Pliny ('Hist. Nat.' xxxv. 12, 43), it was in Greece the origin of the imitative arts; an enamoured Corinthian maid traced the profile of her lover around his shadow cast by a lamp upon the wall.

The most ancient portraits extant, if they can be termed such, are those which have been found in the cases of mummies: there is a singularly fine specimen of these preserved in the Egyptian museum of the Louvre in Paris; and there is also one in the British Museum.

It was a custom among the ancients, in very early times, for warriors to have their portraits painted upon their shields, called by the Romans *imagines clipeorum*, or *imagines clipeatæ*, and these shields were frequently dedicated in the temples in honour of their owners when deceased, or placed by victors as trophies (clipei votivi). The portraits were most probably painted in wax, but that they were well executed is very doubtful. (Pliny, xxxv. 3.)

Among the Romans, in the time of the republic, the possession of the portraits of their ancestors (*imagines majorum*) was a proof of nobility, for by the *jus imaginum* none were permitted to make portraits of themselves except those who had themselves or whose ancestors had borne some curule magistracy; and Roman families were accustomed to boast of their *famosæ imagines* as a proof of their ancient nobility. (Cic., 'In Pisonem,' 1.) These portraits or images, which were of wax, were preserved with much care by their posterity, and were only brought out upon great occasions or carried before them in funeral processions. (Pliny, xxxv. 2.) They were probably painted busts, for the art of casting with wax in plaster moulds taken from the life was, according to Pliny (xxxv. 12, 44), invented as early as the time of Alexander, by Lysistratus the brother of Lysippus. It seems that the Romans were also sometimes in the habit of prefixing the portraits of authors to their works. Martial mentions one of Virgil (xiv. 186).

The most ancient portrait-painter of extraordinary merit on record was apparently Dionysius of Colophon: he is praised by Aristotle ('Poet.,' 2) for the fidelity of his paintings; and from what Plutarch says ('Timol.,' 36) of the high finish of his works, we may perhaps term him the Holbein of antiquity: he flourished, as nearly as can be ascertained, shortly after the time of Polygnotus and Phidias, about 430 B.C.

The most famous portrait-painter among the ancients was Apelles: he enjoyed the exclusive privilege of painting the portraits of Alexander: one of his most celebrated pictures was a portrait of that monarch as Jupiter, called the "Alexander Ceraunophoros," for which, according to the incredible account of Pliny (xxxv. 10, 36), he received 20 talents of gold (upwards of 50,000*l.* sterling); so large a sum, that it was measured to the painter, not counted ("mensura, non numero"). Most of the pictures of Apelles were portraits in an extended sense, yet it is doubtful whether before the time of the Roman emperors there was a distinct class of painters who confined themselves to portraits ("imaginum pictores:" Pliny, xxxv. 11, 40). Even in the great days of Italian art there was not a distinct class of portrait painters as in the present times; and it is an incontestable fact, that although upon the whole the number of good portrait painters has very much increased, still portrait-painting itself has not improved since such has become the practice.

The success of a portrait depends upon the sitter as well as upon the painter, and it may be spoiled by the bad taste of the one or the other. Excellence in portraiture consists in placing every feature in its proper place, in a correctness of modelling, a judicious arrangement of light and shade suited to the complexion of the subject, and in tasteful attire and an unaffected and simple attitude; the former are within the province of the painter, the latter in that of the sitter. Much of the character may be shown by the posture, and the painter should adopt that which appears most natural to his sitter, for the habits of nature must be distinguished from those of fashion; no defect is more striking in a portrait than a forced and affected attitude.

In every portrait the countenance of the person represented should constitute the picture; all accessories must be kept subordinate to the principal object, and should not engage the attention except when expressly examined, for they are the mere adjuncts necessary to indicate the character, rank, or nation of the original. Upon these principles a good portrait must be a good picture, for the beauty of a picture consists in the harmony of the whole in composition, colour, and execution: and when every part has received no more of the painter's attention than its local importance requires, a picture cannot in any particular deviate from the truth, simplicity, and unity of nature. Fancy costumes are injurious to portraits as portraits, for a general resemblance being the principal object of portraiture, the subject should be clothed as usual, and the more simple the attire, the more prominent and consequently the more important will be the head, which is the principal object. Whatever deviations are allowed from this principle, although the picture may perhaps gain in pictorial effect, it must lose as a portrait. A mere insipid transcript of the features, and an equally minute attention to the detail of the accessories, are a degradation of portrait. There is no other difference between historical painting and portrait painting than that portrait exacts a stricter attention to the individual character, and consequently requires a more careful execution of the head, but the draperies and accessories should be equally bold and free as in historical painting. Large canvasses, and what are termed full-lengths, are ill suited to portrait, and the latter are seldom successful even under the most able hands. How often we see a great field of canvass, where the head is a mere speck, and is generally lost in the mass of accessories, of trees, columns, or draperies; these are pictures of robes, not of men, and are only tolerable as state portraits, when the insignia of rank or office are more important than the individuals. Such should be termed Iconics (*εἰκονικοί*) rather than portraits.

Expression is perhaps the most important study in portrait. To represent the true character of an individual, the countenance should be painted in repose, when no particular sentiment or passion predominates; for an otherwise good picture may be rendered a very bad portrait through the injudicious adoption of some transitory expression, or the introduction of a smile put on for the occasion, when perhaps the mouth is smiling whilst the eyes are languid and fatigued. The expression may be also materially injured by exaggerating the local tints, which in most cases has the effect of changing the complexion, and the particular expression of every individual depends upon the complexion as well as upon the relative proportions of the features. It is by accurately giving these proportions that what is called a striking likeness is produced, and this may be accomplished without entering into any minute detail of the parts; the features are indicated rather than expressed: this is a principle of historical painting, but is a style only fit for the portraits of public characters, or such as are to be placed in spacious localities, and must be viewed at a distance.

Such portraits, when even of only tolerable resemblance, are generally pronounced to be striking likenesses, especially by those who have but an imperfect knowledge of the persons represented; for they are themselves unacquainted with any more of the physiognomy of the originals than they see expressed in the pictures. These portraits however lose their resemblance either upon close inspection or upon a prolonged view.

The most successful painters of portrait in modern times have been Lionardo da Vinci, Raffaelle, Sebastian del Piombo, Giorgione, Paris Bordone, Titian, Velasquez, Holbein, Hals, Rembrandt, and Vandyck; and the following pictures are amongst the finest specimens of portrait painting extant:—his own portrait by Lionardo da Vinci, in the portrait gallery at Florence; Andrea Doria, by Sebastian del Piombo, in the Palazzo Doria at Rome; the head of Guido, by Simone Cantarini, in the Academy at Bologna; Titian and Aretin, by Titian, in the royal collection at Windsor; Pope Innocent X., by Velasquez, in the Palazzo Doria at Rome; the Meyer Family, by Holbein, in the gallery at Dresden; and the head of Gevartius, by Vandyck, in the National Gallery in London.

Of the portrait painters of more recent times, Mengs, Reynolds, Gainsborough, David, Gerard, and Lawrence have enjoyed the greatest celebrity.

POSEIDON (Ποσειδῶν), one of the deities of the Greek Olympus.

The attributes of the Roman *Neptunus* or *Neptumnus*, are nearly the same as those of the Greek Poseidon. Poseidon was the son of Kronos and Rhea, and the brother of Zeus and Hera, and appears to have been one of the ancient divinities of Greece; although, according to Herodotus (ii. 50), he was not originally a Greek deity, but was introduced from Libya. Poseidon was the god of the water in general, of the sea, the rivers, and the fountains; but he was more particularly regarded as the god of the sea, which he acquired as his share in the division of the dominions of his father Kronos. His wife was Amphitrite, and their son Triton.

Poseidon is said to have produced the horse in his contest with Athene for the right of naming the city of Athens. It is difficult to give a reason for the connection of Neptune with the horse; but it is evident from several passages in the Greek writers that he was regarded as a kind of equestrian deity, as well as the god of the sea. (Aristoph., 'Knights,' l. 449.) Poseidon had a magnificent palace beneath the sea at Ægæ ('Il.,' xiii. 20). The animals offered to him in sacrifice were usually black bulls, rams, and boar pigs.

Poseidon was not originally a god of the Doric race. He was principally worshipped by the Ionians, who were in most places a maritime people. In those Dorian cities, however, which had acquired a love for foreign commerce, we find that the worship of Poseidon prevailed extensively; as, for instance, at Tænarum, whence it was carried to Tarentum, at Cyrene, in Ægina, and more particularly on the Corinthian isthmus, and at Trœzen, from which place the worship of this god was transmitted to Posidonia in Italy. (Müller's 'Dorians,' vol. i., p. 417, 418, tr.)

The etymology of the names Poseidon and Neptunus is doubtful. Poseidon is written in Doric Greek, Poteidan (Ποτειδᾶν), of which we have another example in the name of Potidæa, written Poteidain (Ποτειδαία) in the inscription, now in the British Museum, on those Athenians who fell before |this city. The name, according to some writers, contains the same root, in the first syllable, as we find in ποτός and ποταμός. Neptunus is derived by Cicero from *nando* ('Nat. Deor.,' ii. 26); and by Varro from *nuptu*, because this god covers (*obnubit*) the earth with the sea ('De Ling. Lat.,' iv. 10); but neither of these derivations has the least show of probablity. We may compare the form of the word Nept-unus or -umnus, with Port-umnus, Vert-umnus, and the word al-umnus; but the meaning or origin of the root *Nept* or *Nep* seems uncertain. It may perhaps be connected with the same root as is contained in the Greek νίπ-τω.

The statues of Poseidon resembled in many respects those of Zeus; but the figure of the former was more angular, and there was less of repose and thoughtfulness in the countenance. The Greek sculptors gave a certain degree of roughness to the statues of Poseidon, which appears to have been regarded as appropriate to the god of the ocean. His hair was usually somewhat in disorder, and the whole of his figure was represented as exceedingly powerful and muscular. Hence the "chest of Poseidon" (στέρνον Ποσειδάωνος, 'Il.,' v. 479) is the poetic expression for this characteristic of the deity, which is illustrated by the noble fragment from the pediment of the Parthenon in the British Museum. He was usually fully draped. His right hand held the trident; and he was frequently represented accompanied by Amphitrite, or surrounded by Nereids, Tritons, dolphins, and other marine personages and objects. (Müller, 'Archäologie der Kunst,' §§ 354–56; 'Denkmaler der Alten Kunst.')

POSITIVE. [Negative Quantities.]

POSSE COMITA'TUS (literally, the power of a county) comprise all able-bodied males within the county between the ages of 15 and 70 years. All such persons, without any exception, are bound to aid the sheriff in all matters that relate to his office; and he is fineable if he neglect to avail himself of their aid. In case of any invasion, rebellion, riot, &c., or breach of the peace within the county, all such persons, on pain of fine or imprisonment, are bound to attend him on being charged by him to do so, and to assist in opposing and suppressing them. They may come armed, and are justified in killing a person in case of resistance. The power of the county may also be raised when necessary for the purpose of apprehending traitors, felons, &c., and that even within particular franchises. It is lawful for any peace-officer, (and perhaps even for a private person,) to raise a competent number of people for the purpose of opposing and suppressing enemies, rebels, rioters, &c. within the county; but such persons are punishable if they use unnecessary violence. It is also the duty of the sheriff or any minister of the king having the execution of the king's writs, or process even in a civil nature, who meets with actual resistance in his attempt to execute them, to raise a power sufficient to quell the resistance. (2 Inst., 193, 194; 3 Inst., 161; 1 Hawk., P.C., 152, 156.)

POSSESSIO FRATRES. [Descent.]

POSSESSION. In endeavouring to explain the legal meaning of this term, we shall commence with the following extracts from Savigny's work on the Right of Possession ('Das Recht des Besitzes,' Giessen, 1827.)

"All the definitions of possession are founded on one common notion. By the notion of possession of a thing we understand that condition by virtue of which not only are we ourselves physically capable of operating upon it, but every other person is incapable. This condition, which is called detention, and which lies at the foundation of every notion of possession, is no juristical notion, but it has an immediate relation to a juristical notion, by virtue of which it becomes a subject of legislation. As ownership is the legal capacity to operate on a thing at our pleasure, and to exclude all other persons from using it; so is detention the exercise of ownership, and it is the natural state which corresponds to ownership as a legal state. If this juristical relation of possession were the only one, everything concerning it that could juristically be determined, would be comprehended in the following positions:—the owner has the right to possess; the same right belongs to him to whom the owner gives the possession; no other person has this right.

"But the Roman law, in the case of possession, as well as of property, determines the mode in which it is acquired and lost; consequently it treats possession not only as a consequence of a right, but as a condition of rights. Accordingly, in a juristical theory of possession, it is only the right of possession (jus possessionis) that we have to consider, and not the right to possess (called by modern jurists jus possidendi), which belongs to the theory of property.

"We now pass from the notion of mere detention to that of juristical possession, which is the subject of this treatise. The object of the first part, which is the foundation of the whole investigation, is to determine this notion formally and materially. Formally, by explaining those rights which presuppose possession as a condition, and consequently determining the signification which the non-juristical notion of detention obtains in jurisprudence, in order to its being considered as something juristical, that is, Possession; materially, by enumerating the conditions which the Roman law requires for the existence of possession, and consequently the positive modifications under which detention can be viewed as possession.

"The formal determination of the notion by force of which alone possession can become a subject of jurisprudence, is divided into three parts; first we must determine the place which possession, as a legal relation, occupies in the system of Roman law. We must then enumerate the rights which the Roman law recognises as a consequence of possession, and we must also examine the rights which are improperly considered rights of possession. It will then be easy to answer the questions whether possession is to be considered as a right, and whether as a jus in re. The first and simplest mode in which possession appears in a system of jurisprudence consists in the owner having the right to possess; but we are here considering possession independent of ownership, and as the source of peculiar rights; the former of these two questions therefore may be expressed thus—in what sense has possession been distinguished from ownership? a mode of expression which has been used by many writers.

"In the second place we must determine how the different senses in which possession occurs in the Roman law are distinguished from one another by the mode of expression; and particularly what were the significations of possessio generally, and possessio naturalis, and possessio civilis, among the Roman jurists.

"In the whole system of Roman law there are only two consequences which can be ascribed to possession of itself, as distinct from all ownership, and these are usucapion and interdicts.

"The foundation of usucapion is the rule of the Twelve Tables, that he who possesses a thing one or two years becomes the owner. In this case bare possession, independent of all right, is the foundation of property, which possession must indeed have originated in a particular way, in order to have such effect; but still it is a bare fact, without any other right than what such effect gives to it. Accordingly it is possession itself, distinct from every other legal relation, on which usucapion, and consequently the acquisition of ownership, depends.

"Possessorial interdicts are the second effect of possession, and their relation to possession is this: possession of itself being no legal relation, the disturbance of possession is no violation of a legal right, and it can only become so by the circumstance of its being at the same time a violation of a legal right. But if the disturbance of possession is effected by force, such force is a violation of right, since every forcible act is illegal, and such illegal act is the very thing which it is the object of an interdict to remedy. All possessorial interdicts then agree in this: they presuppose an act which in its form is illegal.[*]

"Now since possessorial interdicts are founded on such acts as in their form are illegal, it is clear why possession, independent of all regard to its own rightfulness, may be the foundation of rights. When the owner claims a thing as his property (vindicatio), it is a matter of perfect indifference in what way the other party has obtained possession of it, since the owner has the right to exclude every other person from the possession of it. The case is the same with respect to the interdict, by which the 'missio in possessionem' is protected: this interdict is not a possessorial interdict, for the 'missio' itself gives no possession, but it gives a right to detention, and this right is made effective in the same way as in the case of property. On the other hand, he who has the bare possession of a thing has not on that account any right to the detention, but he has a right to require from all the world that no force shall be used against him. If however force is used and directed against the possession, the possessor protects himself by means of the interdicts. Possession is the condition of these interdicts, and in this case, as in the case of usucapion, it is the condition of rights generally.

[*] Possessorial interdicts were not limited to cases of violence; they comprehended the three *vitia possessionis*. (Terence, 'Eunuch.,' ii. 3; v. 37.)

"Most writers take quite a different view of the matter, and consider every violation of possession as a violation of a legal right, and possession consequently as a right of itself, namely, presumptive ownership, and possessorial plaints as provisional vindications. This last, which is the practical part of this opinion, is completely confuted in a subsequent part of this treatise; but it is proper to show here how far such a view is true, as this may be a means of reconciling conflicting opinions. The formal act of illegality above mentioned is not to be so understood, as if possessorial interdicts were a necessary consequence of the independent juristical character of force, and obviously sprung out of it. This consequence of force, namely, that possession of the thing must be restored to the person who has been ejected, without regard to the question whether or not he has any right to the thing, is rather simply a positive rule of law. Now if we ask for the reason of this kind of protection being given against force, that is, why the ejected party should recover the possession to which he may possibly have no title, it may be replied, that the reason is the general presumption that the possessor may be the owner. So far then we may view possession as a shadow of ownership, as a presumed ownership; but this view of the matter only extends to the establishment of the rule of law in general, and not to the legal reason for any particular case of possession. This legal reason is founded rather in the protection against the formal injury, and accordingly possessorial interdicts have a completely obligatory character, and can never be viewed as provisional vindications."

The special object of Savigny's essay may be collected from these passages. The legal principles here developed are applicable to every system of jurisprudence. There must always be a distinction between the right to possess, which is a legal consequence of ownership, and the right of possession, which is independent of all ownership. The owner of a thing may not have the possession, but he has a right to the possession, which he must prosecute by legal means. The possessor of a thing, simply as such, has rights which are the consequences of his possession; that is, he is legally entitled to be protected against forcible ejection or fraudulent deprivation; his title to a continuance of his possession is good against all persons who cannot establish their right to the thing, and this continued possession may, according to the rules of positive law in each country, become the foundation of ownership. It may be that the acquisition of possession may also be the acquisition of ownership, or that the acquisition of possession may be essential to the acquisition of ownership. Thus, in the case of occupation, the taking possession of that which has no owner, or the acquisition of the possession, is the acquisition of the ownership. Also, when a thing is delivered by the owner to another, to have as his own, the acquisition of the possession is the acquisition of the ownership. In these examples, ownership and possession are acquired at the same time, and there is no right that belongs to the possessor as possessor: his rights are those of owner. But the form and mode of the acquisition of the possession, viewed by itself as distinct from the acquisition of the ownership, will also be applicable to the cases of possession when possession only is acquired. For possession of itself is a bare fact, though it has legal consequences; and being a bare fact, its existence is independent of all rules of the civil law or of the jus gentium, as to the acquisition and loss of rights. (Savigny, p. 25.)

Having shown that in the Roman law all juristical possession has reference to usucapion and interdicts, and that the foundation of both is a common notion of juristical possession, Savigny proceeds to determine the material conditions of this notion.

In order to lay the foundation of possession as such, there must be detention, and there must also be the intention to possess, or the "animus possidendi." Consequently the "animus possidendi" consists in the intention of exercising ownership. But this ownership may either be a person's own ownership or that of another: if the latter, there is no such "animus possidendi" as makes detention amount to possession. In the former case a man is a possessor, because he treats the thing as his own: it is not necessary that he should believe it to be his own.

Whether then we are considering possession as such, or that possession which is concurrently acquired with ownership, or which completes the acquisition of, or is the exercise of, ownership, the material facts of possession are the same. When ownership is transferred from one man to another, every system of law must require some evidence of it. But the evidence of the transfer of ownership may be entirely independent of the evidence of acquisition of possession; and also the evidence of the acquisition of possession may be inseparable from that of the acquisition of ownership. There must then generally be some act which shall be evidence of the acquisition of possession, whether possession as such is obtained without ownership, or possession accompanied by ownership, or possession as necessary to the complete acquisition of ownership, or possession as simply the exercise of ownership.

Bracton, the oldest law writer from whom we obtain any comprehensive notion of our whole system, has framed his notions of possession on and borrowed his definitions from the Roman law. Whether he has always rightly understood them is a matter that would require a very careful investigation.

Bracton (c. 17) uses possessio and seisina as synonymous. He observes that it is not sufficient for one man's right to be transferred to another, unless that other obtain "seisina;" and he adds, "possessio sive seisina multiplex est." He defines possessio to be "corporalis rei detentio i., corporis et animi cum juris adminiculo concurrente." He therefore limits it to corporeal things, for incorporeal things are incapable of tradition or delivery, but may be said "quasi possideri;" and he requires both the corporeal act and the animus together with right, in order to give possessio, which, thus understood, is complete ownership. Accordingly verus possessor is owner. (Fleta, iii., c. 3, s. 1.) He divides possessio into "civilis, quæ animo tantum tenetur," that is, in which there is an intention to hold; and "naturalis, quæ corpore;" and this latter may be just, that is, with good title; or unjust, that is, without good title. To acquire complete possession, it must be acquired "animo et corpore:" there must be both the mental affection *possidendi affectus* (as Bracton elsewhere calls it, fol. 40) and the corporeal act; possession can only be completely lost "animo et corpore," for it may be lost "corpore," and retained "animo." Among various kinds of possession he enumerates nuda, where a person has no right to the thing; and vestita, where he has "jus, titulus, tempus." As an instance of a case, where there is "nihil juris in re, sed aliquid possessionis," he mentions the case of a man being seised or possessed by intrusion. As another kind of possession, but which is manifestly distinguishable from the others, he mentions the possession of a custos creditor, or any person of the kind. These examples will be sufficient to show that the senses of possessio at that time were very various. The essential part of all of them is detentio.

In the transfers of freeholds, mentioned by Bracton, traditio or livery is defined to be "in possessionem inductio de re corporali;" as soon as this traditio is made by the owner, the person to whom it is made has "liberum tenementum," a freehold estate (Bracton, fol. 39), "propter conjunctionem juris et seisinae et mutuum utriusque partis consensum."

A person who held land for a term of years (firmarius) had no "liberum tenementum" (fol. 27), but he was certainly said "possidere," but there was not the "conjunctio juris et seisinae," that is, a possessio which made a liberum tenementum. Again (c. 15), when Bracton is treating of one cause or title of possession being turned into another, he says that he who has the usus fructus and the terminus, or term of years, may, during its continuance, and while he is thus in possession, acquire "liberum tenementum," if the proper formalities are observed, "so that there shall not be wanting proof of the new acquisition." It appears that the owner (dominus) was not said to possess during the continuance of the term; for it is said (fol. 32) "that the donor and true owner, with the consent of the tenant (tenens), might change one title of possession into another without any change of the possession; nor is it necessary to resume the thing that has been once given and possessed, in order that it may be possessed by a new title."

It remains to attempt to show some of the many senses in which possession has been or is still used in English law. There seems to have been always a fundamental distinction as to the use and meaning of this word, between land and moveable chattels, of which something more will presently be said. Some of our old writers make the following division of possession as applied to land: "Possession is actual and in law: *actual* possession is when a man actually enters lands and tenements to him descended; possession *in law* is when lands and tenements descend to a man, and he hath not yet actually entered into them." (Staundf., 'Pl. Cor.,' fol. 198; Cowel.) Now, this actual possession, that is, possessio according to Bracton's definition, is the only possession included in this definition, that is, properly so called. The possession in law is merely the owner's right to possess. This possession in law, that is, ownership and the right to possess is not full ownership, for if the right to possess is not exercised, that is, does not become an actual possession, it will be lost in course of time. (3 & 4 Wm. IV., c. 27.) It becomes an actual possession by entry, that is, by the owner entering on the land or exercising ownership over it. What shall be sufficient to constitute entry so as to give the owner all the advantages of actual possession, may sometimes be difficult to determine; but actual entry is not always necessary for that purpose. The receipt of the rent from a lessee for years, who has the actual possession of the land, gives to the owner all the legal advantages which are derived from his actual entry.

A lessee for years, who pays a rent, has the actual possession of the premises, and if the landlord enters the premises, except when rent is in arrear, or by virtue of the covenants in the lease, he is a trespasser. Still the owner who receives the rents is often said, in a sense, to be in possession, though he may never have had actual possession. This sense of possession is that which is expressed in the recent Statute of Limitations by the words "receipt of the profits." It might be called "legal possession," as it is for many purposes a possession which gives all the advantages of actual possession. But since "legal possession" has been used in a different sense, as will be shown hereafter, the expression cannot conveniently be applied in the case here considered. Nor can we use the phrase "possession in law;" for that, as above defined, is the owner's right to possess, that is, his present right to actual possession, which in the case here supposed, the owner has not. There appears then to be no one term, except possession simply, that can be used to express that kind of possession of land which a man has who has merely received rent from a lessee.

Possession, when coupled with the word estate, means a present right to possess. "An estate in possession gives a present right of present enjoyment;" "an estate in reversion gives a present right of future enjoyment." (Preston, 'Estates,' i. 89.) In this sense of possession, an estate in possession is opposed to an estate in remainder or reversion; but it does not imply actual possession. In the third section of the Act for the Limitations of Actions and Suits (3 & 4 Wm. IV., c. 27), an "estate or interest in possession" is opposed to an "estate or interest in reversion or remainder," and the actual possession of land is referred to in the same section by the terms "possession or receipt of the profits of the land." [STATUTE OF LIMITATIONS.]

A man is said to be *seised* of a freehold estate; but he is said to be *possessed* of a chattel real. The Statute of Uses does not apply to chattels real.

It remains to speak of a distinction in the word possession as applied to a real estate and a chattel personal. Both may be possessed, but the legal conclusion from the bare fact of possession is different in the case of a real estate and of a personal chattel. "There is a marked difference between a real estate and a personal chattel: the latter is held by possession; a real estate, by title. Possession of an estate is not even *primâ facie* title. It may be by lease only or from year to year." (Lord Eldon, Hiern *v.* Mill, 13 Ve., 114.) This seems to mean that, in the case of a chattel, possession is a presumption of ownership; but that possession of land is not; at least not a presumption of a freehold interest. Still it is so far a presumption of some interest, that if a man buys an estate from the owner, knowing that another man is in possession of it, he has notice of whatever interest the person in possession may have in the land; and therefore if the person in possession has a prior contract with the owner for purchasing the land, the second purchaser buys subject to the interest of the person in possession. (Daniels *v.* Davison, 16 Ve., 249; 17 Ve., 433.)

It has been already stated that *actual* possession of land, or what is legally considered actual possession, is necessary in order to give the owner all the advantages of ownership. In the case of chattels personal, ownership is frequently acquired without or rather before actual possession, and it may always be so acquired by contract when the thing agreed to be bought and sold is clearly determined. Sometimes the ownership can only be acquired together with the possession, because the thing only becomes determined by the act of delivery or taking possession. In all cases, however, when personal chattels are bought and sold, it is often a matter of great nicety to determine whether there has been possession by the purchaser, either as the condition or means of establishing his ownership, or for the purpose of ascertaining from what time a thing has ceased to be in one person's possession and come into the possession of another.

Questions as to this matter often arise in cases of loss, of insolvency of a vendee, &c., when the chattel is transferred from the vendor to the vendee by being *sent*, in which case it is of necessity during a certain time on its journey, or as our law expresses it, *in transitu*. The solution of questions of this kind, which often occur in a commercial country, is sometimes difficult, though many general principles are deducible from judicial decisions. The right of the vendor to stop the thing after it has commenced its journey, continues till the time at which the vendee is legally considered to have acquired possession. [STOPPAGE IN TRANSITU.]

It is remarked by Savigny ('Das Recht des Besitzes,' p. 185), "that in the whole theory of possession nothing seems easier to determine than the character of corporeal apprehension which is necessary to the acquisition of possession. By this fact all writers have understood an immediate touching of the corporeal thing, and have accordingly assumed that there are only two modes of apprehension: laying hold of a moveable thing with the hand; and entering with the foot on a piece of land. But as many cases occur in the Roman law in which possession is acquired by a corporeal act, without such immediate contact, these cases have been viewed as symbolical acts, which, through the medium of a juristical fiction, become the substitute for real apprehension." After showing that this is not the way in which the acquisition of possession is understood in the Roman law, and that there is no symbolical apprehension, but that the acquisition of possession may in all cases be referred to the same corporeal act, he determines what it is, in the following manner:

"A man who holds a piece of gold in his hand is doubtless the possessor of it; and from this and other similar cases has been abstracted the notion of a *corporeal contact generally* as the essential thing in all acquisition of possession. But in the case put, there is something else which is only accidentally united with this corporeal contact, namely, the physical possibility to operate immediately on the thing, and to exclude all others from doing so. That both these things concur in the case put, cannot be denied: that they are only accidentally connected with corporeal contact, follows from this, that the possibility can be imagined without the contact, and the contact without the possibility. As to the former case, he who can at any moment lay hold of a thing which lies before him, is doubtless as much uncontrolled master of it as if he actually had laid hold of it. As to the latter, he who is bound with cords has immediate contact with them, and yet one might rather affirm that he is possessed by than that he possesses them. This physical possibility then is that which as a fact must be contained in all acquisition of possession: corporeal contact is not contained in that notion, and there is no case in which a fictitious apprehension need be assumed."

This clear exposition of a principle of Roman law is applicable to all systems of jurisprudence which have received any careful elaboration, for the principle is in its nature general. It may be that the expounders of our law have not always clearly seen this principle, even when they have recognised it; and it may be that they have not always acted upon it. Still it appears from various cases that the physical possibility of operating on a thing is the essential character of the acquisition of possession in English law.

POSSIBLE and IMPOSSIBLE. The first of these words is of little interest, except as the contradictory of the second. The word *impossible* is used in common life to signify highly improbable, or utterly incredible. In this sense the impossible of yesterday is the possible of to-day. It is also used to signify that which would contradict the *laws of nature*, by which we always mean our view, knowledge, or experience of the laws of nature. In this sense also the impossible of yesterday is the possible of to-day. It was *impossible* that a missile should be thrown by the hand, and after traversing the air return to the hand again, until the boomerang of the savage found its way to the knowledge of the physical philosopher.

The true use of the word *impossible* is that which its etymology demands, that which *cannot be*. And how can we acquire the idea of that which *cannot be*, in the universe of an *omnipotent* Creator. On examination of the question, we arrive at no result but this, that all we can grasp of *impossibility* is *inconceivability*, and that every thing is conceivable which does not *contradict itself*, let it contradict what else it may. And thus (MATHEMATICS, col. 430) we arrive at the conclusion that nothing is impossible except that which contradicts the laws of thought, or the laws of the necessary matter of thought. Impossibility, then, is a word of logic and mathematics, and nothing else. It is impossible that "every X is Y" and "some Xs are not Ys," should both be true: it is impossible that two sides of a triangle should be less than the third.

But are we not, under this restriction, converting the *impossible* into the *possibly possible?* May there not be notions which though self-contradictory to *our* minds, are not so to minds of another stamp, or of a higher stamp. This question has been discussed before now: it has been asked *whether God could make two and two to be five*. In order to make this question intelligible, that is, to show that it is beyond intelligible answer, we must assert, without being able to go into full deduction, that every one of our impossibilities is resoluble into the idea of something which at once exists *and* does not exist. In the two and two which make five, there is an extra unit which *is* there and *is not*. When Euclid shows an impossibility he does it by showing that the notion requires a whole which is no greater than its part: so that the additional part which makes up the whole exists without existence. That is to say, in compassing an impossibility we start from this enunciation—

> To be *and* not to be—that is the question.

Now when we are seriously asked—Is it in the power of the Creator to make the same thing to exist and not to exist at the same moment—we answer that our minds are so constructed that it looks very much as if we were *intended* to believe that it is *not*. And there we leave it: we would rather employ ourselves on the old question of the schoolmen,—which God loves best, a *possible* angel, or an *existing* fly.

But there is another point of view, from which the question might have been asked, and which perhaps lurked in the minds of those who first asked it. Can the Creator make two *and* two to be five?

The simplest mode of relation, that which we signify by *and*, gives four. But it is not beyond conceivability that a mind might be so constructed that its simplest operation should be different from ours. It would not cost Mr. Babbage an hour's thought to alter the fundamental structure of his difference-engine in such a manner that, instead of adding the two numbers presented, the machine should, of necessity, throw in an extra unit. That which man can execute, he can conceive the Creator performing on a larger scale: accordingly, it is within possibility that a mind should exist in which the simplest junction, to that mind, of two and two gives five, but the mode of junction would not be what we call *addition*.

The main purpose of such an article as the present is to bring forward the true meaning, in our laws of thought, of the word *impossible;* and to help the reader, should he need such help, to avoid importing the true meaning of the word into the phrases, "morally impossible," and "physically impossible." The word here used should be *incredible*. A confusion of this sort very frequently exists. The mind allows experience to fashion a *law of nature*, and postulates that the future shall agree with the past, and obey that law. This postulate once assumed, disobedience is an impossibility, *also assumed:* for simultaneous obedience and disobedience would be simultaneous existence and non-existence. But the question whether the law of nature, or what is assumed to be the law of nature, shall continue without exception for ever, cannot be argued upon the assumption that the settlement shall be of one preconcerted kind.

An eminent experimenter has laid down the following as his mode of proceeding: and that he does not intend the words *possible* and *impossible* to be used in their vague and popular sense is evident from his repeating the dictum, without remark or explanation, after full warning of what he seemed to be doing. "Before we proceed to consider any question involving physical principles, we should set out with *clear ideas* of the naturally possible and impossible." No doubt if there be a naturally possible and impossible, which is more than our experimenter can know, and if he can get a clear idea of it, which is more than he can do, his plan is a very good one. In the meanwhile, situated as we are in this world, we believe that a remark [*] made by Arago, a year before the above method was propounded, is much more to the purpose. It is that he who pronounces the word *impossible*, except in pure mathematics [to which logic ought to be added], shows a lack of prudence.

POST-OBIT BOND (*Post Obitum*, Lat.), a bond given for the purpose of securing a sum of money, the condition of which is, that the money shall be paid on the death of some person.

POST-OFFICE.—*History*. Correspondence is the offspring of advanced civilisation. When the state of society in this country anterior to the seventeenth century is considered, there can be little surprise that we hear nothing of a post-office before that period. Few of the motives to written communication could be said to exist. Each district of the country supplied its own wants. The little foreign trade which flourished was conducted between the English buyer and the foreign seller in person, at the port where the import was made. Literature and science dwelt only in the convent or the cell. There was little absence from the domestic hearth, excepting that of the fighting man following the service of his lord; but few, either servants or masters, had the power, even if they had the will, to write letters. The king summoned his barons from all quarters of the kingdom by letters, or writs, and held frequent communication with his sheriffs, to collect his parliament together, to muster his forces, to preserve his peace, to fill his treasury. The expenses of the establishment of Nuncii, charged with the conveyance of letters, formed a large item in the charges of the royal household. As early as the reign of King John, the payments to Nuncii for the carriage of letters may be found enrolled on the Close and Misse-Rolls, and these payments may be traced in an almost unbroken series through the records of subsequent reigns. Nuncii also formed part of the establishment of the more powerful nobles. In a wardrobe account of the 27th year of Edward I., we find a specimen of the mode in which the payment is entered:—"x die Januarii nuncio Domini Regis de Hastang redeunti ad eundum dominum suum cum litteris Regis, pro expensis suis sic redeundo—xiii." As correspondence grew, it is easy to see that economical arrangements for its transmission would grow likewise. The Nuncius of the time of King John was probably obliged to provide his own horse throughout his journey; whilst in the reign of Edward II. he was able, and found it more suitable, to hire horses at fixed *posts* or stations. In 1481, Edward IV., during the Scottish war, is stated by Gale to have established at certain posts, twenty miles apart, a change of riders, who handed letters to one another, and by this means expedited them 200 miles in two days. It would seem that the posts, at which relays of riders and horses were kept, were wholly private enterprises; but that, when their importance became felt and appreciated, the state found it both politic and a source of profit to subject them to its surveillance. Before any substantive evidence appears of the superintendence of the posts by the government, the superscription often met with, of "haste poste haste," on letters written at the close of the fifteenth and beginning of the sixteenth centuries, is sufficient to show that the posts had become the customary channel for transmitting letters in the speediest way.

A statute in 1548 (2 and 3 Edw. VI., c. 3) fixed a penny a mile as the rate to be chargeable for the hire of post-horses. In 1581, one Thomas Randolph is mentioned by Camden as the chief postmaster of England; and there are reasons for concluding that his duties were to superintend the posts, and had no immediate connection with letters. The earliest recital of the duties and privileges of a postmaster seems to have been made by James I. The letters patent of Charles I., in 1632 ('Pat.,' 8 Car. I. p. i. m. 15 d; 'Fœdera,' vol. 19, p. 385) recite that James constituted an office called the office of postmaster of England for foreign parts being out of his dominions. This functionary was to have "the sole taking up, sending, and conveying of all packets and letters concerning his service, or business to be despatched into forraigne parts, with power to grant moderate salaries;" the office was "graunted to Mathewe le Quester, and Mathewe le Quester his son: all others were publiquely prohibited that they should not directly or indirectly exercise or intrude themselves: the said M. le Quester made and substituted William Frizell and Thomas Witherings his deputies, and his Majesty accepted the substitution." The king, "affecting the welfare of his people, and taking into his princely consideration how much it imports his state and this realm that the secrets thereof be not disclosed to forreigne nations, which cannot be prevented if a promiscuous use of transmitting or taking up of forreigne letters and packetts should be suffered," forbids all others from exercising that which to the office of such postmaster pertaineth, at their utmost perils.

In 1635, a proclamation was made "for settling of the letter-office of England and Scotland." It sets forth "that there hath been no certain or constant intercourse between the kingdoms of England and Scotland;" and commands "Thomas Witherings, Esq., his Majesty's postmaster of England for foreign parts, to settle a running post or two, to run night and day between Edinburgh and Scotland and the City of London, to go thither and come back in six days." Directions are given for the management of the correspondence between post-towns on the line of road, and other towns which are named, and likewise in Ireland. All postmasters are commanded "to have ready in their stables one or two horses:" 2½*d.* for a single horse, and 5*d.* for two horses per mile were the charges settled for this service. A monopoly was established, with the exceptions in favour of common known carriers and particular messengers sent on purpose, most of which have been preserved in all subsequent regulations of the Post-Office. In 1640, a proclamation was made concerning the sequestration of the office of postmaster for foreign parts, and also of the letter-office of England, into the hands of Philip Burlamachy, of London, merchant; but, in 1642, it was resolved by a committee of the House of Commons, that such sequestration was "a grievance and illegal, and ought to be taken off," and that Mr. Wytherings ought to be restored. As late as 1644, it appears that the postmaster's duties were not connected directly with letters. A parliamentary resolution entered on the Journals of the Commons states that, "the Lords and Commons, finding by experience that it is most necessary, for keeping of good intelligence between the parliament and their forces, that post stages should be erected in several parts of the kingdom, and the office of master of the posts and couriers being at present void, ordain that Edmund Prideaux, Esq., a member of the House of Commons, shall be, and is hereby constituted, master of the posts, messengers, and couriers." "He first established a weekly conveyance of letters into all parts of the nation, thereby saving to the public the charge of maintaining postmasters to the amount of 7,000*l.* per annum." (Blackstone.) An attempt of the Common Council of London to set up a separate Post-Office, in 1649, was checked by a resolution of the House of Commons, which declared "that the office of postmaster is, and ought to be, in the sole power and disposal of parliament."

But the most complete step in the establishment of a Post-Office was taken in 1656, when an act was passed "to settle the postage of England, Scotland, and Ireland." This having been the model of all subsequent measures, induces us to give something more than a passing notice of it. The preamble sets forth "that the erecting of one general Post-Office for the speedy conveying and recarrying of letters by post to and from all places within England, Scotland, and Ireland, and into several parts beyond the seas, hath been and is the best means not only to maintain a certain and constant intercourse of trade and commerce between all the said places, to the great benefit of the people of these nations, but also to convey the publique despatches, and to discover and prevent many dangerous and wicked designs which have been, and are, daily contrived against the peace and welfare of this commonwealth, the intelligence whereof cannot well be communicated but by letter of escript." It also enacted that, "there shall be one Generall Post-Office, and one officer stiled the postmaster-generall of England and comptroller of the Post-Office." This officer was to have the horsing of all "through" posts and persons "riding in post." Prices for letters, whether English, Scotch, Irish, or foreign, and for post-horses, were fixed. All other persons were forbidden to "set up or imploy any foot-posts, horse-posts, or pacquet-boats." These arrangements were confirmed in the first year of the Restoration, by an act which was repealed 9 Anne, c. 11. In 1683, a metropolitan penny-post was set up, the history of which is given at length in the 'Ninth Report of the Commissioners of Post-Office Inquiry.' From 1711 to 1838, upwards of 150 acts affecting the regulations of the Post-Office were passed. In the first year of her present Majesty, ninety-nine of these were repealed, either wholly or partially, and the following acts were passed, by which the whole department of the Post-Office was regulated:—

For the management of the Post-Office, c. 33.

The regulation of the duties of postage, c. 34.

For regulating the sending and receiving of letters and packets by the post, free from the duty of postage, c. 35.

For consolidating the laws relative to offences against the Post-Office, and explaining certain terms and expressions, c. 36.

A mere enumeration of the titles of all the acts affecting the Post-Office would occupy a considerable space. An account even of these four last-mentioned acts must be dispensed with, and the reader referred to the acts themselves. Their enactments have been abrogated, to a great extent, by the adoption of Mr. Rowland Hill's plan of uniform postage, which we shall notice hereafter. This measure was carried into effect by an act passed in 1839, 2 & 3 Vic. cap. 52, which conferred temporary powers on the Lords of the Treasury to do so, and was subsequently confirmed by an act 3 & 4 Vic., c. 96, passed 10th August, 1840.

Rates of Postage.—The first establishment of a rate of postage for carrying letters occurs in 1635, in the proclamation already described. The rates were fixed as follows :—

---

[*] Celui qui, en dehors des mathématiques pures, prononce le mot *impossible*, manque de prudence. ('Annuaire' for 1853, p. 445.)

Under 80 miles	2*d.* single letter.	
Between 80 miles and 140 miles . . .	4	"
Above 140 miles	6	"
On the borders and in Scotland . . .	8	"

"Two, three, four, or five letters in one packet, or more, to pay according to the bigness of the said packet."

The rates, both inland and foreign, fixed by the ordinance of the Commonwealth in 1656, are therein fully detailed. Letters above two sheets were charged by weight. In most cases, the rates vary but little from those fixed in the 12 Car. I., the principal of which were as follows :—

Letter not exceeding one sheet, to or from any place not exceeding 80 miles, 2*d.*; above 80 miles, 3*d.* From London to Berwick, 3*d.*; to Dublin, 6*d.* Letters of two sheets were charged double. By the 9 Anne, c. 11, a penny was added to several of the rates previously established; a letter from London to Edinburgh was charged 6*d.* Additions were subsequently made; but the principle of the rating was to charge according to the distance which the conveyance travelled, until the year 1839, when the direct distance only was charged. A single letter was interpreted to mean a single piece of paper, provided it did not exceed an ounce in weight. A second piece of paper, however small, or any inclosure, constituted a double letter. A single sheet above an ounce was charged with fourfold postage. After a fourfold charge, the additional charges advanced by weight.

In Scotland, letters, when conveyed by mail-coaches only, were subject to an additional halfpenny. Letters passing between Great Britain and Ireland were subject to the rates of postage charged in Great Britain, besides packet rates, and Menai, Conway Bridge, or Milford rates.

Between 1814 and 1839, the rates in Ireland were as follows :—

Distances in Irish Miles.	Rates for Single Letters.	Distances in Irish Miles.	Rates for Single Letters.
7	2*d.*	95	9*d.*
15	3	120	10
25	4	150	11
35	5	200	12
45	6	250	13
55	7	300	14
65	8		

The postmaster-general had authority to establish penny posts for letters not exceeding in weight four ounces, in, from, or to, any city, town, or place in the United Kingdom (other than London or Dublin), without any reference to the distance to which the letters are conveyed.

The principle which guided the department in establishing penny posts was, to select small towns and populous neighbourhoods, not situated in the direct lines of general-post conveyances, and desirous of obtaining that facility, wherever such penny post did not afford the means of evading the general post, and promised to yield a return that would pay for its maintenance. The rule was to consider whether the receipts on the first setting up of the post would pay about two-thirds of the charge. The Post-Office took its chance of the remainder being made good.

The London Twopenny Post extended to all letters transmitted by the said post in the limits of a circle of three miles' radius, the centre being the General Post-Office in St. Martin's-le-Grand, which limits the postmaster-general had authority to alter. The London Threepenny Post extended to all letters transmitted by the said post beyond the circle of three miles' radius, and within the limits of a circle of twelve miles' radius, the centre being the General Post-Office.

The select committee of the House of Commons, in 1838 and 1839, which investigated Mr. Rowland Hill's plan, reported the following to be the average rates of postage :—

AVERAGE RATES, MULTIPLE LETTERS BEING INCLUDED AND COUNTED AS SINGLE.

	d.	*d.*
Packet and ship letters	23·1562	= nearly 23¼
Ditto, and inland general-post letters . .	9·7065	= nearly 9¾
Ditto, ditto, and London 2*d.* and 3*d.* post letters	8·4006	= nearly 8½
Ditto, ditto, ditto, and country 1*d.* post letters	7·6074	= little more than 7½
Inland general-post letters only . . .	8·6502	= nearly 8¾
Ditto, and London 2*d.* and 3*d.* post letters . .	7·4688	= nearly 7½
Ditto, ditto, and country 1*d.* post letters .	6·7414	= nearly 6¾

AVERAGE RATES, MULTIPLE LETTERS BEING EXCLUDED.

Single inland general-post letters . . .	7·7445	= nearly 7¾
Ditto, and London 2*d.* and 3*d.* post letters .	6·8202	= little more than 6¾
Ditto, ditto, and country 1*d.* post letters . .	6·2166	= nearly 6¼

Franking.—As early as a post-office was established, certain exemptions from the rates of postage were made. Parliamentary franking existed in 1666. An entry is registered on the Journals of the House of Commons on 19th October 1666, "That Edward Roberts be sent for in custody of the serjeant-at-arms, or his deputy, to answer his abuse and breach of privilege in exacting money of the members of this House for post-letters." In the paper bill which granted the Post-office revenue to Charles II., a clause provided that all the members of the House of Commons should have their letters free, which clause was left out by the Lords, because no similar provision was made for the passing of their letters; but a compromise was made on the assurance that their letters should pass free.

In 1735 the House of Commons prosecuted some investigations into the subject, which appear on the Journals. Again, in 1764 (4 Geo. III.), a committee was appointed "to inquire into the several frauds and abuses in relation to the sending or receiving of letters and parcels free from the duty of postage." Among various abuses proved to exist, it is related that "one man had in the course of five months counterfeited 1200 dozen of franks of members of parliament, and that a regular trade of buying and selling franks had been actually established with several persons in the country." Resolutions restricting and regulating the privilege were passed. From time to time the privilege was extended, until it was finally abolished, with a very few exceptions, on 10th January, 1840.

Seven millions of franks, out of sixty-three millions of general-post letters, including franks, were estimated in 1838 to pass through the Post-Office annually. The relative quantities of these several documents are given in the 'Third Report of the Commons' Committee,' as follows :—

				Single Letters.
56,000,000	of general-post chargeable letters, equivalent at	1⅛	to	63,000,000
4,813,448	parliamentary franks . . .	2	to	9,626,896
2,109,010	official franks	8	to	16,872,080
77,542	copies of the statutes . . .	13	to	1,008,046
63,000,000				90,507,022

The privileged letters, therefore, reduced to the standard of single letters, amounted to above 30 per cent. of the whole number of letters transmitted by the general post.

The average weight of a single chargeable letter was about 3-10ths of an ounce; the average weight of a parliamentary frank about 48-100ths of an ounce; that of an official frank, 1·9376 oz., or nearly two ounces; and that of a copy of a public statute, 3·1129 oz. Had they been liable to the then existing rates, they would have contributed in the following proportions to the revenue :—

	Number.	Rate per Letter.	Revenue.
		d.	£
Parliamentary franks .	4,813,448	17·392	384,814
Official franks . . .	2,109,010	70·209	616,965
Statutes distributed .	77,542	112·795	36,443
Totals . . .	7,000,000	....	1,002,222

Newspapers, with a few exceptions, passed free of postage. All franking is now altogether abolished, except petitions forwarded to peers and members of parliament.

Revenue.—The statistics of the Post-Office revenue are far from complete. In the early period of the Post-Office establishment, and before 1716, only a few scattered accounts can be collected. In 1653 the annual revenue was farmed for 10,000*l.*, and in 1659 for 14,000*l.* (Journals of the Commons.) In 1663 it was farmed for 21,500*l.* annually, and the amount settled on the Duke of York. In 1674 the farming of the revenue yielded 43,000*l.* In 1685 it produced 65,000*l.* Parliament resumed the grant after 1688, though the king continued to receive the revenue. In 1711 the gross revenue was reckoned at 111,426*l.* From 1716 to 1733 the average yearly net revenue was 97,540*l.*, founded upon "a certain account, and not an estimate." (Commons Journals, April 16, 1735.) In the Postage Reports of 1838 (vol. ii., App., p. 176; vol. i., p. 511) are accounts showing the gross receipt, charge of management, net receipt, and rate per cent. of collection in Great Britain from 1758 to 1837, and in Scotland and Ireland from 1800 to 1837. The accounts for a few years will serve to show its progress :—

GREAT BRITAIN.

Years ended April 5.	Gross Receipts.	Charges of Management.	Net Receipt (returns deducted).	Rate per cent. of Collection.		
	£	£	£	£	*s.*	*d.*
1758	222,075	148,345	73,730	66	15	11
1769	305,058	140,298	164,760	45	19	9
1779	402,918	263,670	139,248	65	8	9
1786	506,500	220,525	285,975	43	10	9
1799	1,012,731	324,787	657,888	32	1	4
1816	2,193,741	594,045	1,526,527	27	1	6
1837	2,206,736	609,220	1,511,026	27	12	1

SCOTLAND.

Years.	Gross Receipts.			Charges of Collection.			Net Income.			Rate per cent. of Collection.		
	£	*s.*	*d.*	£	*s.*	*d.*	£	*s.*	*d.*	£	*s.*	*d.*
1800	100,651	14	4	16,896	8	0	83,755	6	4	16	15	0
1837	220,758	13	10	59,945	7	1	160,813	6	9	27	0	0

IRELAND.

Years.	Gross Receipts.	Charges of Collection.	Net Receipt (Returns deducted).	Rate per cent. of Collection.
	£	£	£	£ s. d.
1800	84,040	59,216	24,824	70 9 2
1837	255,070	95,548	134,809	37 9 2

The revenue for the United Kingdom for the years ended January 5, 1838 and 1839, was as follows :—

Years ended Jan 5.	Gross Receipts.	Charges of Collection.	Returns.	Net Receipts.	Rate per cent. of Collection.
	£	£	£	£	£ s. d.
1838	2,462,269	669,940	122,531	1,669,798	27 4 1
1839	2,467,216	669,756	120,938	1,676,522	27 2 11

The Select Committee on Postage, in 1838, instituted the following comparison between the Post-Office revenue of the six years ending 5th January, 1838, and that of six years ending 5th January, 1821 :—

	Gross Revenue, excluding Repayments.		Net Revenue, after deducting cost of Management.	
See Appendix to Report I., p. 509.	1815 to 1820 inclusive.	1832 to 1837 inclusive.	1815 to 1820 inclusive.	1832 to 1837 inclusive.
	£	£	£	£
	2,273,843	2,175,292	1,598,295	1,531,828
	2,323,835	2,190,181	1,619,196	1,553,425
	2,186,634	2,209,439	1,537,505	1,513,052
	2,099,225	2,243,294	1,433,871	1,564,458
	2,151,213	2,350,603	1,467,533	1,645,835
	2,108,833	2,339,738	1,522,640	1,658,479
Totals of the six years	13,143,583	13,508,547	9,179,040	9,467,077
Average of the six years	2,190,597	2,251,424	1,529,840	1,577,846
Increase at the end of seventeen years	60,827	..	48,006	..
Annual average increase	3,578	..	2,823	..

It thus appeared that on an average gross revenue of 2,190,597*l.* there had been in seventeen years a positive increase of 60,827*l.*, averaging only 3578*l.* yearly, or little more than 1½ per thousand, though the advance had been rapid in population, and still more so in wealth, industry, and trade.

Establishment, Cost of Management, &c.—The head of the Post-Office is styled the Postmaster-General, under whose authority are placed all the post-offices in the United Kingdom and the colonies. The office was formerly held by two persons. It is considered a political one, and the holder relinquishes it with a change of ministry. The Commissioners of Post-Office Inquiry (4th Report) recommended that the office should be exercised by three permanent commissioners; and a bill passed the Commons to give effect to the recommendation, but was thrown out by the Lords.

In 1831 and 1832 the chief offices of London, Dublin, and Edinburgh were remodelled by the Duke of Richmond, then postmaster-general. The separate office of postmaster-general for Ireland was abolished, and other changes were made, which were estimated to reduce the expenses above 4700*l.* per annum. In London the saving was estimated at 6448*l.* per annum: a secretary at Dublin and at Edinburgh is chief executive officer for the respective countries.

The metropolitan General Post-Office was removed in 1829 from Lombard Street to St. Martin's-le-Grand. It is the head-quarters of all post-office business. All accounts of the collection of the revenue and the expenditure are rendered there.

No accounts of the number of documents passing through the Post-Office were kept until shortly before the introduction of Sir Rowland Hill's system. Founded upon a very careful examination of the best data, the numbers, the result of very elaborate calculations, are appended to the 'Report of the Commons' Committee;' as here subjoined :—

Description of Letters.	Yearly Number of Letters.	Average rate per Letter.	Yearly Revenue.
		d.	£
Packet and ship letters . . .	3,523,572	23·1562	369,340
General-post inland letters above 4*d*.	46,378,800	9·2224	1,782,191
Ditto, not exceeding 4*d*. . . .	5,153,200	3·5	75,151
London local-post letters . .	11,837,852	2·3266	114,753
Country penny-post letters . .	8,030,412	1	33,483
Total	74,923,836	7·6074	2,374,923
Parliamentary franks . . .	4,813,448	..	..
Official franks, for public purposes .	2,109,010	..	..
Public statutes	77,542	..	..
Newspapers	44,500,000	..	..
Total of documents transmitted by post	126,423,836	..	2,374,923
Unappropriated			4,641
Total revenue from letters, 1837			2,379,564

See Notes to 'Postage Report,' pages 4 and 6.

The chargeable letters in the mails leaving London were found to weigh only 7 per cent. of the whole weight of those mails. The total weight of the chargeable letters and franks carried by the thirty-two mails leaving London was only 2912 lbs. Deducting one-half as the weight of the franks and franked documents, the weight of all the chargeable letters was only 1456 lbs., being 224 lbs. less than the weight which a single mail is able to carry.

The management of the conveyance of the mails by sea and land was subject, of course, to those constant changes which arise out of the improvements daily taking place in the various modes of transit. Certain packets were exclusively controlled by the Admiralty, to whose charge they were removed in 1837; others remained with the Post-Office; but the whole are now placed under the Post-Office management. The parliamentary returns and reports of various commissioners on the subject of the packet-service are numerous. The most important are—'The Twenty-second Report of the Commissioners of Revenue Inquiry,' part 5, printed 1830, and the 'Sixth Report of the Post-Office Commissioners on the Packet Establishments,' printed in 1836. Contracts for the conveyance of the mail-bags to the Continent are made between the Post-Office and the proprietors of certain steam-vessels. The Post-Office moreover has power of sending a bag of letters in any private ship.

The inland correspondence is carried by railroads, by four-horse and two-horse coaches; by cars in Ireland, by single-horse carts, on horse-back, and foot.

The number of miles travelled over in England and Scotland by the mail-coaches in the following years, was as follows :—

1834 . . .	5,911,006	1837 . . .	6,643,217
1835 . . .	5,931,218	1838 . . .	7,204,295
1836 . . .	6,233,478	1839 . . .	7,377,857

And a parliamentary return, printed 1836 (No. 364), presented the following account of the speed and cost of the mail-coaches :—

	England. Miles.	Ireland. Miles.	Scotland. Miles.
Greatest speed travelled per hour .	10⅝	9¼	10¼
Slowest	6	6⅛	7
Average speed	8⅞	8	8¾

The system of mail-coaches owes its origin to Mr. Palmer. In 1784, Mr. Palmer, who was manager of the Bath and Bristol theatres, laid a plan before Mr. Pitt, which was adopted by the government, after much opposition from the functionaries in the Post-Office. The greatest improvement in the transmission of the correspondence of the country was effected by this plan. Mr. Palmer found the post, instead of being the quickest, nearly the slowest conveyance in the country; very considerably slower than the common stage coaches. The average rate of speed did not exceed three miles and a half per hour. Whilst coaches left London in the afternoon and reached Bath on the following morning, the post did not arrive till the second afternoon. Slowness was not the only defect: it was also irregular, and very insecure. The robbery of the mail was very common. Mr. Palmer succeeded in perfecting the mail-coach system, and in greatly increasing the punctuality, the speed, and security of the post. At least 500 places obtained a daily delivery of letters, which before received them not oftener than three times in the week.

The net revenue before these changes had averaged for twenty years about 150,000*l.* a year. In ten years after Mr. Palmer's plan had been in work, the net revenue increased to 400,000*l.*; in twenty years it became 700,000*l.*; and in thirty years it had reached a million and a half, from which sum it can hardly be said to have advanced to the time of the adoption of Sir Rowland Hill's system. The reader will find both the history and progress of Mr. Palmer's plan, of the Post-Office opposition, and the subsequent proceedings arising out of his claims, fully related in parliamentary papers, printed by order of the House of Commons in 1807, 1808, and 1813.

In 1838 a plan calculated not only to increase the utility of the Post-Office in the promotion of all the objects of civilisation, but to change the whole management of the institution, was brought forward by Mr. (now Sir) Rowland Hill, a gentleman wholly unconnected with the department. It was at first privately submitted to the government, and subsequently published in a pamphlet under the title of 'Post-Office Reform—its Importance and Practicability.' In a short period three editions were issued. The main features of Mr. Hill's plan, which putting aside the merits of the suggestion of a uniform rate, is discussed with singular moderation, acuteness, caution, and sound reasoning, proposed to effect—1, a great diminution in the rates of postage; 2, increased speed in the delivery of letters; and, 3, more frequent opportunities for their despatch. He proposed that the rate of postage should be uniform, to be charged according to weight, and that the payment should be made in advance. The means of doing so by stamps were not suggested in the first edition of the pamphlet, and Mr. Hill states that this idea did not originate with him. A uniform rate of a penny was to be charged for every letter not exceeding half an ounce in weight, with an additional penny for each additional ounce. Mr. Hill discovered the justness and propriety of a uniform rate in the fact that the cost attendant on the transmission of letters was not measured by the distance they were carried. He showed on indisputable data that the actual cost of conveying letters from

London to Edinburgh, when divided among the letters actually carried, did not exceed one penny for thirty-six letters. Independently of its fairness, the obvious advantages of simplicity and economical management were strongly in favour of a uniform rate.

The publication of this plan immediately excited a strong public sympathy in its favour, and especially with the commercial classes of the city of London. Mr. Wallace moved for a select committee to inquire into its merits on the 9th May, 1837; but the motion fell to the ground. On the 30th May, 1837, Lord Ashburton, upon presenting a petition from some of the most eminent merchants, bankers, men of science, and others in the metropolis, to the House of Lords, spoke strongly in favour of the plan. In the December of the same year the government assented to the appointment of a select committee to inquire into and report upon the plan. A society of merchants was forthwith formed in the city of London to furnish evidence of the evils of the high rates of postage, and the insufficiency of the Post-Office management in answering the wants of the present times. The subject began to excite much interest throughout the country. In the session of 1837 five petitions were presented to the House of Commons in favour of the plan. In 1838 upwards of 320 were presented, of which number seventy-three emanated from town councils, and nineteen from chambers of commerce. After sitting upwards of sixty-three days, and examining Mr. Rowland Hill and eighty-three witnesses, besides the officers of the departments of the Post-Office and the Excise and Stamp offices, the committee presented a most elaborate report in favour of the whole plan, confirming by authentic and official data the conclusions which Mr. Hill had formed from very scanty and imperfect materials.

The appearance of the committee's report seemed to inspire the whole country with confidence in the plan. Petitions in its favour amounting to 2000 were presented to both houses of parliament in the session of 1839. The Duke of Richmond, then postmaster-general, advised the government to adopt it; and the chancellor of the exchequer brought forward a bill to enable the Treasury to carry the plan into effect, which was carried by a majority of one hundred in the House of Commons, and passed into law on the 17th August, 1839. In the following month an arrangement was made which secured Mr. Rowland Hill's superintendence of the working out his own measure. On the 5th December, 1839, as a preparatory measure, to accustom the department to the mode of charging by weight, the inland rates were reduced to an uniform charge of 4*d.* per half ounce. The scale of weight for letters advanced at a single rate for each half ounce up to sixteen ounces. Other reductions were made in the packet-rates; and the London district post was reduced from 2*d.* and 3*d.* to 1*d.* This measure continued in force until the 10th January, 1840, when a uniform inland rate of postage of 1*d.* per half ounce, payable in advance, or 2*d.* payable on delivery, came into operation. On this day parliamentary franking entirely ceased. On the 6th May stamps were introduced. The warrants of the lords of the Treasury which authorised these changes were published in the London Gazette of the 22nd November, 28th December, 1839; 25th April, 1840.

The first entire year of the penny postage was 1840, but then letters might be paid, or stamped, or were charged double. In that year 191,931,365 letters passed through the post-offices of the United Kingdom. The revenue derived from the Post-Office had been 1,649,088*l.* in 1839; in 1840 it only amounted to 495,514*l.* In 1845 the number of letters had reached 329,161,811, and the revenue 760,588*l.* The number of letters and the amount of net revenue continued to increase rapidly. In 1848 the additional advantage was given of a book-post, by which single books could be sent, open at the ends, at an uniform rate of 6*d.* per pound. This privilege was gradually extended to the British colonies. In 1855 the rate of postage for printed sheets was reduced to 1*d.* for a quarter of a pound, 2*d.* for half a pound, and 2*d.* extra for each fraction above half a pound; but if 4*d.* or upwards were paid, the packet might contain any number of sheets written or printed, except that the writing must not be of the nature of a letter. The last regulation issued in 1857 is that the packet may contain, in every case, any number of sheets, written or printed, but the written matter must not be of the nature of a letter, and may consist of bound books, or maps or prints on rollers, or whatever is necessary to the safe transmission of literary or artistic matter, such packets, however, not to exceed two feet in length, depth, or width, and all must be open at the ends or sides. Such packets may also be sent to all the British colonies at the rate of 3*d.* for 4 oz., 6*d.* for 8 oz., and then proceeding at the rate of 6*d.* for every 8 oz., or portion thereof, except to Ascension Island, the East Indies, Hong Kong, Australia, New Zealand, and the Gold Coast, to all of which the rates are one-third more, and the weight is restricted to three pounds. By various conventions the foreign postage of letters has been materially reduced, in some cases 50 per cent., and in others varying from 17 to 20 per cent. The rates to all the British colonies were in 1857 reduced to an uniform rate of 6*d.* per half-ounce, payable in advance.

The sixth annual return of the Post-Office for 1859 states that the total number of letters delivered in the year was 545,000,000, of which 446,000,000 were in England and Wales, 47,000,000 in Ireland, and 52,000,000 in Scotland. These numbers give an average, in England, of 22 letters for each person of the population (in London it amounts to 43 for each), in Ireland of 7 for each, and in Scotland of 16 for each person. The number of newspapers passing through the Post-Office was 70,500,000, more than half of which bore the newspaper stamp. The number of book-packets was about 11,000,000. There were 470,000 newspapers, and 1,900,000 letters that from various causes could not be delivered, chiefly from illegible or erroneous directions. The gross revenue (including the produce of the impressed stamps on newspapers, received by the Inland Revenue Office) was 3,448,074*l.*; the cost of management, 2,312,114*l.* (including 444,519*l.* for mail-packets, defrayed by the Admiralty, but fairly chargeable to the Post-Office), which, added to the net revenue, 1,135,960*l.*, equals the revenue derived from the Post-Office in 1838; while the number of letters delivered has increased by 460,000,000. The cost of management includes the following items:—Salaries, pensions, &c., 1,037,525*l.*; buildings, 32,081*l.*; conveyance of mails by railways, 446,000*l.*; by coaches, carts, &c., and wages of mail-guards, 168,507*l.*; by mail-packets (when paid for by the Post-Office) and private ships, 5454*l.*; for manufacture of postage-stamps, 25,940*l.*; miscellaneous, including conveyance of mails in the colonies, under the postal direction of the postmaster-general, the conveyance of the mails through Egypt, clothing for letter-carriers and guards, rents, taxes, law expenses, &c., 138,446*l.*

In November, 1840, a most important improvement was introduced by an increased facility in transmitting small sums of money. The Post-Office had been accustomed to give orders on local post-offices for sums under 5*l.* 5*s.*, for which they charged 5 per cent.; and as the order was on a separate sheet, it involved double postage. The order was next given on a sheet of letter-paper, which saved a postage; later, the charge was reduced to a fixed sum of 1*s.* 6*d.* for sums between 2*l.* and 5*l.*, and 6*d.* for sums less than 2*l.* These charges were reduced to 6*d.* and 3*d.* respectively: the effect was prodigious. In the three months ending Feb. 5, 1841, the amount paid on such orders was 59,432*l.*, against 8141*l.* in the corresponding months of 1840. For some time, however, the expenses of the Money-Order Office, for which a distinct staff had to be organised, exceeded the profits. But the increase of business has been continuous, and money-orders are now the source of a large revenue, except in Ireland. In 1859 the total number of money-orders issued in the United Kingdom was 6,969,108, to the amount of 13,250,930*l.*, an increase of 4¾ per cent. over 1858. Of the total number, 5,932,133 orders, to the amount of 11,358,057*l.*, were issued in England; 498,828, to the amount of 891,675*l.*, in Ireland; and 538,147, to the amount of 1,001,298*l.*, in Scotland. The commission gave a profit, after deducting expenses, in England, of 27,780*l.*, and in Scotland of 2019*l.*; in Ireland there was a loss of 684*l.* The number of orders gives an average of 1 for every 3 persons in England, for every 6 in Scotland, and for every 13 in Ireland. Money-order offices have also been established at Malta, Gibraltar, and in Canada.

In 1855 some important improvements in matters of detail were introduced with great success. Country letters to London, or passing through London, were either sorted at the provincial offices or during their transmission, and this expedited the morning delivery in London by nearly an hour. Pillar letter-boxes were also erected in London, Edinburgh, and Dublin; they have been since extended to most considerable places in the United Kingdom. In 1859 there were 825 head offices, 10,587 sub-offices, and 1958 road letter-boxes; a total of 13,370 public receptacles for letters, against 4518 before the establishment of the penny postage. London was also divided into 10 districts, each having a district head-office, by which letters posted in a district for a neighbouring place are spared the loss of time incurred by transmission to the chief office, and thus a more speedy delivery is attained; and this division also greatly facilitates the sorting of inland letters; but to effect this, the initial letters of East Central, West Central, North, East, South, West, North East, North West, South East, and South West, must be distinctly placed at the end of the direction after "London." A book, price one penny, has been published, distinguishing all the streets and places within the different districts.

Nearly every town of any size throughout the three kingdoms has at least two deliveries a day from and to its metropolis and the larger provincial towns. In 1859 there were 77 such towns added to the list. In the same year the mails within the United Kingdom were conveyed daily over 140,321 miles of way; of this, 35,604 miles are by railway, at an average rate of 9¼*d.* a mile; 32,936 by coaches, mail-carts, &c., at an average of 2¼*d.* a mile; 68,964 by carriers on foot, at an average rate of 1½*d.* a mile; and 2817 miles by packets and boats between different places in the United Kingdom, at rates varying from 5*s.* 6¼*d.* a mile to ¼*d.*

The total number of persons engaged in the service of the Post-Office for the United Kingdom was 24,802, on December 31, 1859, including 1 postmaster-general; 5 secretaries, assistant secretaries, and secretaries for Ireland and Scotland; 15 surveyors; 18 other superior officers, such as heads of departments, chief clerks in the metropolitan offices, &c.; 11,235 postmasters; 1682 clerks (exclusive of some employed temporarily); 197 guards; 11,076 letter-carriers, messengers, &c.; 7 marine officers; 125 postmasters, clerks, &c., in the colonies; and 61 agents in foreign countries. Of this number about 2000 are attached to the London staff, and (including this number) about 3300 are employed in the London district.

The third annual report of the postmaster-general for 1856, in an appendix, states that "in no part of the United Kingdom has more been done for the welfare of the people by the use of railways for carrying mails and by the penny postage system than in Ireland." In 1784 there were posts six days a week on only four lines of road; letters to all other places being conveyed only twice or thrice a week. Now there are daily posts to almost every village, and there is but one important town that has not two daily mails both with London and Dublin. In 1784 the whole expense of the office in Ireland was 15,000*l.*, including salaries of provincial postmasters and the conveyance of mails. Out of this sum, 5500*l.* only was allotted to the provinces; the sum allotted in 1856 for the like service was 134,000*l.*, divided thus: —conveyance of mails by railways, 65,505*l.*; by coaches and cars, 27,168*l.*; by foot-messengers, 10,334*l.*; and salaries and wages paid in provincial offices, 31,122*l.* In 1829 the cost of conveying the mail by mail-coaches was nearly four times the average rate of England; this excess has now disappeared, and in 1859 the average rate per mile was for England 2½*d.*, for Scotland 2¾*d.*, and for Ireland 2*d.*

The same paper pays a just tribute to the exertions of Mr. Bianconi for the improvement of intercommunication in Ireland, particularly in reference to the transmission of letters.

The amount of postage collected at different towns in the United Kingdom (including the postage-stamps sold by the Post-Office and by the Board of Inland Revenue) shows some curious results. London, of course, through which passes nearly one-half of the total correspondence of the kingdom, attains a great predominance, the amount in 1857 being 833,952*l.*; Liverpool, with 255,000 inhabitants, contributed 104,865*l.*; while Manchester, with 316,000 inhabitants, only contributed 89,765*l.*; and Birmingham, with 232,000 inhabitants, but 42,107*l.* Bristol, with about 100,000 inhabitants (including Bedminster), furnished 31,264*l.*; Leeds, with 172,000 inhabitants, only 23,844*l.*; and Sheffield, with 135,000 inhabitants, no more than 16,565*l.* In Ireland the contributions were more in accordance with the size of the towns: Dublin contributed 60,391*l.*; Belfast, 15,547*l.*; Cork, 11,915*l.*; and Limerick, 7115*l.* In Scotland:—Edinburgh, with 160,000 inhabitants, contributed 59,177*l.*; and Glasgow, with 358,000 inhabitants, only 68,377*l.* It must be recollected, however, that in many cases some towns are used as a sort of depôt, from whence postage-stamps are distributed over a wider district than others.

POSTING, from the French "poste," derived from the Low Latin word "posta" (Ducange, *in verbo*), is so called from horses being placed at certain stations or posts, where they may be hired by individuals at their pleasure. The application of the words "post" and "postmaster" as well to the transmission of letters and the persons to whom this business is entrusted, as to stations where post-horses are kept, and the persons who own or have the care of them, is the cause of much confusion: and it frequently cannot be understood in reference to which branch early writers intend these terms to be applied. The ambiguity is not confined to the English language. Post-horses were first established by the governments on the continent of Europe in the 13th and 14th centuries for the conveyance of despatches; they were occasionally employed for the conveyance of persons connected with such governments, and gradually by passengers in general. Posting continues in most countries to be carried on by the state, which retains the monopoly of supplying post-horses, and usually of forwarding mails and diligences. The prices are fixed by the governments, as well as the number of horses that must be employed, according to the weight or number of persons to be conveyed, or even by the state of the roads. In the United States and British North America there is at present (1859) no posting, at least in the sense in which the term is commonly used; that is to say, a person cannot have his carriage conveyed in such a direction as he may wish, and hire fresh horses at convenient stages. He must engage an "extra exclusive" in some principal town, and the same horses must convey him throughout his whole journey, unless another large town should lie on the road. This is the mode of travelling known on the Continent by the name of "vetturino," "voiturier," or "Lohnkutscher." The want of the power of posting is not so inconvenient as might be supposed, for the number of private carriages is not large, and in districts where there is much travelling, communication is usually facilitated by steam-boats, railways, and stage-coaches.

Posting is very generally established in England, but is now less used in consequence of the introduction of railways. In frequented and populous districts, change of horses may commonly be procured at intervals of from eight to twelve miles, and in the most remote and thinly inhabited at inns not more than from fifteen to twenty miles apart. The trade is wholly in the hands of private speculators. The rate of travelling with post-horses varies according to the weight of the carriage and the number of horses employed; from eight to nine miles an hour may be stated as the average rate of a pair of horses under ordinary circumstances. The number of horses hired depends solely on the will and discretion of the party hiring, which are controlled by no legal regulation whatsoever. The payment is estimated per mile for each pair of horses, without reference to the number of persons conveyed, and a second pair of horses is charged at the same rate as the first; the payment to the postmaster does not include the driver, who expects a gratuity of about three-pence a mile. Four horses is the greatest number ever required for one carriage. Sixteen or eighteen pence per mile is the usual price for each pair of horses, and when the payment of postboys and turnpikes is added, a journey will be found to cost about twenty-two pence a mile. If a post-chaise or fly be required as well as post-horses, no additional charge is made on account of the carriage. Post-chaises are now almost things of the past; but flys with a single horse are to be had at most towns, and all large inns, at about 1*s.* a mile. The price of posting is nearly uniform throughout England, but there is considerable variation in the degree of goodness of the horses and chaises provided. On much-frequented roads, where there is generally competition in the posting trade, the accommodation is very superior to what is found at little-frequented inns, where an inferior description of post-horse is kept, which is often insufficiently fed because it is not frequently employed. A postmaster pays yearly for one horse and carriage, 7*l.* 10*s.*; for two, 12*l.* 10*s.*; increasing with the number, for a licence to let post-horses.

POSTULATE (*postulatum*, *αἴτημα*), a thing required to be granted, or the use of which in reasoning is *demanded*.

The distinction between a postulate and an axiom lies in this—that the latter is admitted to be self-evident; while the former may be agreed upon between two reasoners and admitted by both, but not as a proposition which it would be impossible to deny. The distinction above made is really necessary; for example, writers on the evidences of Christianity assume the existence and attributes of the Creator as postulates: they take them for granted. A person who is in the habit of not distinguishing the senses to which the words postulate and axiom have been affixed above, might say they assume the existence and attributes above mentioned as axioms, by which another person might understand things necessarily indisputable; while the writers themselves only mean by the assumption, that what they take for granted has been previously proved by writers on natural theology; or, at any rate, that until they are admitted, the question of the evidences cannot be entered upon. The confusion which prevails as to the use of the word axiom would be lessened by the introduction and proper use of the word postulate, which is our reason for adding these few words to what has been said under AXIOM.

POTASH. [POTASSIUM.]

POTASH ALUM. [ALUM.]

POTASSA. [POTASSIUM.]

POTASSIUM (K). This metal was discovered in 1807 by Sir Humphry Davy. Most of its compounds had been known for years prior to that date, and that the basis of them was a metal, that they were in fact compounds of a metallic oxide, had long been suspected. In that year, however, Davy succeeded in isolating the metal by submitting fused hydrate of potash to the action of a powerful voltaic battery. Potassium has since been obtained by more facile methods, and the following is the one now generally adopted.

Crude bitartrate of potash (argol) is heated in a covered iron pot till gases cease to be evolved. The product—a mixture of carbonate of potash and finely divided carbon—is triturated in a mortar, while still hot, with some coarsely powdered charcoal, and the porous mass promptly transferred to an iron mercury bottle, or other wrought-iron retort. A neck is formed to the bottle or retort by simply screwing into the mouth a piece of iron tube about six inches long, and the whole is then so imbedded in a furnace as that the open end shall project about a quarter of an inch through an opening in that side of the furnace that is purposely formed of plate iron. The fire is now lighted and fed with a mixture of coke and charcoal; an intense white heat is thus produced, and vapours of potassium soon appear at the mouth of the apparatus, and burn with a brilliant purple flame. A receiver is now fitted on, the construction of which needs some care; it may be so formed that the potassium shall drop into naphtha the moment it solidifies; or it may merely be an iron box five inches wide, twelve long, and a quarter of an inch deep, formed by clamping together two very shallow wrought-iron dishes made of plate-iron one-sixth of an inch in thickness. In either case an opening must be made exactly opposite the neck of the bottle, in order to allow of the latter being cleared by a stout steel wire in the event of its becoming stopped up by condensed potassium, &c.; such an opening also allows of the escape of the carbonic oxide gas that is abundantly evolved during the process. The receiver must be kept cool by ice, or other convenient means, and, in the case of the flat box, must, at the close of the operation, be plunged under the surface of rectified Persian naphtha, as otherwise the potassium would quickly become oxidised. The metal thus obtained is not pure, and must be redistilled in a similarly arranged apparatus.

The manufacture of potassium is a somewhat dangerous operation, owing to the frequent formation of explosive compounds. The apparatus in which it has been performed should be immersed in water as soon as cold, for a black detonating compound soon forms by exposure of the residual potassium to the air, and explodes by the slightest friction.

The decomposition that takes place during the manufacture of potassium is primarily a simple case of deoxidation, as expressed in the following equation:—

$$\underbrace{\mathrm{KO, CO_2}}_{\substack{\text{Carbonate of}\\ \text{potash.}}} \quad + \quad \underbrace{\mathrm{C_2}}_{\text{Carbon.}} \quad = \quad \underbrace{\mathrm{3CO}}_{\substack{\text{Carbonic}\\ \text{acid.}}} \quad + \quad \underbrace{\mathrm{K}}_{\text{Potassium.}}$$

Unfortunately, however, the liberated potassium has a great tendency to unite with carbonic oxide, and form a very explosive compound of a grayish colour; it is termed *croconaceous* matter, and when dissolved in water yields croconate and *rhodizonate* of potash.

Potassium has so intense an affinity for other elements that it does not occur in nature in the free state. In combination, however, it is frequently met with. Nearly all land plants contain it, derived mainly from disintegration of feldspar—their ashes consequently yield much carbonate of potash; sea-water also contains a small quantity of potash salts, and nitrate of potash occurs native in large quantities as an efflorescence from the soil in warm climates. [POTASSIUM, in NAT. HIST. DIV.]

Potassium is a bluish-white metal of sp. g. 0·865. At 32° Fahr. it is brittle, and has a crystalline fracture; at ordinary temperatures it is quite soft, and at 130° Fahr. it is liquid. A freshly cut surface possesses high metallic lustre, but it almost instantly becomes covered with a coating of white rust. It may be preserved in the bright state by melting it in one end of a glass tube, from which the air has been expelled by a current of hydrogen, or coal gas, and then allowing it to flow down to the other end of the tube, passing in its course through a small piece of wire gauze; the dross is thus filtered away and the metal obtained in a brilliant lustrous condition. On fusing off, by the aid of a blow-pipe, that part of the tube containing the gauze, &c., then melting the potassium and allowing it to cool very slowly, and when partly solidified rapidly pouring off the liquid portion, the solid potassium is obtained crystallised in quadratic octohedra.

Potassium has a great affinity for oxygen. It will take that element out of almost any combination. Thrown on to the surface of water it rapidly becomes converted into oxide of potassium, and generates sufficient heat to ignite the hydrogen that is set free, the latter carrying off a little vapour of potassium and burning with a beautiful violet flame. At an elevated temperature potassium decomposes carbonic oxide, carbonic acid, or any gas that contains oxygen. In chemical research potassium is frequently used for removing the last traces of oxygen from a hydrocarbon liquid, by rectifying the latter over a small quantity of the metal. From what has been said it is evident that potassium must always be kept in purified rock oil, or naphtha, or some liquid that contains no oxygen.

The equivalent of potassium is 38·96.

Potassium and *oxygen* form three compounds :—

1. Suboxide of potassium	K_2O ?
2. Protoxide of potassium	KO
3. Teroxide of potassium	KO_3

1. *Suboxide of potassium.*—This is formed when potassium is exposed in a close vessel to a very small quantity of air. It is very unstable, and is probably only a mixture of metal and protoxide.

2. *Protoxide of potassium* (KO). *Potash; potassa.*—This *anhydrous* oxide is formed when the metal is exposed to perfectly dry air; or when equivalent weights of water and potassium are brought together in a vessel from which air is excluded. It is very deliquescent, and when moistened with water becomes incandescent.

Hydrated oxide of potassium (KO,HO). *Potash; caustic potash.*—This is best prepared by dissolving carbonate of potash in ten times its weight of water and then gradually adding half its weight of quick-lime, previously slaked and made into a cream with water; carbonate of lime deposits, and caustic potash remains in solution. The resulting liquid frequently contains alumina. Solid hydrate of potash is obtained on evaporating the liquor, just mentioned, until the residue remains in a state of tranquil fusion; it was formerly called *lapis infernalis*. It crystallises in acute rhombohedra. The following is Dalton's table of the strength and boiling point of caustic potash solutions of different specific gravities :—

	Anhydrous Potash (KO).	
Specific gravity.	Per cent.	Boiling Point.
1·68	51·2	329° Fahr.
1·60	46·7	290° „
1·52	42·9	276° „
1·47	39·6	265° „
1·44	36·8	255° „
1·42	34·4	246° „
1·39	32·4	240° „
1·36	29·4	234° „
1·33	26·3	229° „
1·28	23·4	224° „
1·23	19·5	220° „
1·19	16·2	218° „
1·15	13·0	215° „
1·11	9·5	214° „
1·06	4·7	213° „

The *liquor potassæ* of the London Pharmacopœia has a density of 1·063.

3. *Teroxide of potassium* (KO_3) is formed when the metal is burned in excess of oxygen gas, or when caustic potash is fused in contact with air. It is a yellowish brown substance, having a crystalline texture, and readily parts with its oxygen to combustibles, and even on dissolving in water.

Potassium and *phosphorus* may be fused together under rock oil, with production of a chocolate-brown phosphide of potassium. Water decomposes it into hypophosphite of potash and into gaseous and solid phosphuretted hydrogen.

Potassium and *sulphur* form five different compounds, namely :—

1. Protosulphide of potassium	KS
2. Bisulphide of potassium	KS_2
3. Tersulphide of potassium	KS_3
4. Tetrasulphide of potassium	KS_4
5. Pentasulphide of potassium	KS_5

1. The first is formed on heating sulphate of potash in a current of hydrogen. Its colour is yellowish-brown, it is very deliquescent, and cauterises the skin. 2. The second is formed on passing excess of sulphuretted hydrogen through an alcoholic solution of potash, evaporating in the air till it becomes turbid, and then exposing it in vacuo. It is fusible, and of an orange colour. 3. Tersulphide of potassium is obtained on passing bisulphide of carbon vapour over ignited carbonate of potash. 4. The tetrasulphide results when bisulphide of carbon vapour is passed over ignited sulphate of potash. 5. Pentasulphide of potassium is formed when a solution of any of the preceding sulphides is boiled with excess of sulphur; or, mixed with other potash salts, when caustic potash is boiled with excess of sulphur; or when carbonate of potash is fused with excess of sulphur. *Liver of sulphur* is an old preparation, made by fusing together 69 parts of carbonate of potash with 40 of sulphur: it is mainly a mixture of sulphate of potash and tersulphide of potassium. With the exception of the first, all the above sulphides of potassium yield sulphuretted hydrogen and free sulphur on being decomposed by a dilute acid, thus:—

$$KS_n + HCl = KCl + HS + S_{n-1}.$$

Potassium and *selenium* form compounds apparently resembling the sulphides.

Potassium and *iodine* form only one compound, namely,—

Iodide of potassium (KI). *Hydriodate of potash.* This salt is much used in medicine. It may be made by dissolving iodine in caustic potash, evaporating to dryness, and gently igniting the residue to drive off the oxygen from the iodate of potash that is produced at the same time :—

$$\underbrace{6KO}_{\text{Potash.}} + \underbrace{I_6}_{\text{Iodine.}} = \underbrace{5KI}_{\substack{\text{Iodide of}\\\text{potassium.}}} + \underbrace{KO, IO_5}_{\substack{\text{Iodate of}\\\text{potash.}}}$$

Or it may be formed by fusing iodine with excess of iron, decomposing the iodide of iron solution by carbonate of potash, filtering, and evaporating to the crystallising point.

$$\underbrace{FeI}_{\substack{\text{Iodide of}\\\text{iron.}}} + \underbrace{KO, CO_2}_{\substack{\text{Carbonate of}\\\text{potash.}}} = \underbrace{FeO, CO_2}_{\substack{\text{Carbonate of}\\\text{iron.}}} + \underbrace{KI}_{\substack{\text{Iodide of}\\\text{potassium.}}}$$

Iodide of potassium crystallises in white cubes, having a cooling somewhat bitter taste. It is very soluble in water, and, if pure, completely dissolves in six times its weight of alcohol. It readily dissolves iodine, forming a deep brown solution.

Potassium and *bromine* form *bromide of potassium* (KBr). It may be prepared by the same methods as the iodide, substituting bromine for iodine. Its appearance is also similar.

Potassium and *chlorine* form—

Chloride of potassium (KCl). Potassium burns in chlorine with even greater brilliancy than in oxygen; the product is chloride of potassium. This salt may also be formed by dissolving carbonate of potash in hydrochloric acid, and evaporating to the crystallising point. Chloride of potassium is a bye-product in many pharmaceutical and chemical operations, and, from the facility with which it may be decomposed, is useful as a source of other potash salts.

Potassium decomposes *hydrofluoric acid*, and forms *fluoride of potassium* (KF). It crystallises in cubes.

Silico-fluoride of potassium (KF, SiF_2) falls as a transparent gelatinous precipitate on adding hydrofluosilicic acid to a salt of potash. Its formation is sometimes used as a test for potash.

Carbonate of potash (KO, CO_2). This salt is imported in large quantities from Russia and America. It is procured from plants, which for this purpose are burned in dry pits three or four feet deep, the ashes dissolved in water, evaporated until the phosphates, sulphates, chlorides, &c., crystallise out, and the mother liquor then boiled to dryness. Such is the *crude potash* or *pearlash* of commerce; it varies very much in quality, but its value is always determined by the process of ALKALIMETRY. After recrystallisation till pure, it is sent into the market as *salts of tartar*, or *purified pearlashes*.

Chemically pure carbonate of potash may be obtained by heating the bicarbonate to a little below redness, or by deflagrating a mixture of equal parts of nitrate and bitartrate of potash: either product is digested in water, filtered, and evaporated to the crystallising point.

Carbonate of potash crystallises in deliquescent, oblique, rhombic octohedra, containing two equivalents of water of crystallisation (KO

$CO_2+2Aq.$). It has an acrid, soapy taste, is strongly alkaline to test-paper, is soluble in rather more than its own weight of cold water, and in rather less than half its weight of hot water. The strength of its solution may be ascertained by its specific gravity according to Tunnerman's table :—

Specific gravity.	Per cent.	Specific gravity.	Per cent.
1·4812	40·504	1·2282	19·580
1·4750	40·139	1·2150	18·601
1·4626	39·160	1·2020	17·622
1·4504	38·181	1·1892	16·643
1·4384	37·202	1·1766	15·664
1·4265	36·223	1·1642	14·685
1·4147	35·244	1·1520	13·706
1·4030	34·265	1·1400	12·727
1·3915	33·286	1·1282	11·748
1·3803	32·307	1·1166	10·769
1·3692	31·328	1·1052	9·790
1·3585	30·349	1·0940	8·811
1·3480	29·360	1·0829	7·832
1·3378	28·391	1·0719	6·853
1·3277	27·412	1·0611	5·874
1·3177	26·432	1·0505	4·895
1·3078	25·454	1·0401	3·916
1·2980	24·475	1·0299	2·934
1·2886	23·496	1·0198	1·958
1·2694	22·517	1·0098	0·979
1·2554	21·538	1·0048	0·489
1·2417	20·539		

Carbonate of potash is insoluble in alcohol. It fuses at a red heat, and slowly volatilises at a still higher temperature.

Carbonate of potash is largely used in the manufacture of soap and of glass, and is a convenient salt for the preparation of other potash compounds.

Bicarbonate of potash ($KO, HO, 2CO_2$) is formed when moist carbonate of potash is exposed to the influence of a current of carbonic acid. It forms permanent right-rhombic prisms. Its solution is neutral to test-paper, and by long exposure to air or a boiling temperature is gradually reduced to the state of solution of *sesquicarbonate*.

Borates of potash. There are several of these. The biborate crystallises in six-sided prisms, and resembles borax. [BORACIC ACID.]

Phosphates of potash. The different varieties of phosphoric acid [PHOSPHORUS] form salts with potash, but the resulting compounds have no particular interest.

Sulphite of potash (KO, SO_2) and *bisulphite of potash* ($KO, HO, 2SO_2$) may readily be obtained, but the corresponding soda-salts [SODIUM] are nearly always used in their place.

Sulphate of potash (KO, SO_3). *Sal polychrest*. Bisulphate of potash is neutralised with carbonate, and evaporated; the resulting sulphate of potash much resembles quartz in appearance. It requires 16 parts of cold water for solution, but is much more soluble in hot water. It is very hard, and forms double salts with many other protosulphates, and with those sesquisulphates that are isomorphous with sesquisulphate of alumina. [ALUMS.]

Bisulphate of potash ($KO, HO, 2SO_3$). *Sal enixum*. A bye-product in the distillation of hydrochloric or nitric acids. It is much more soluble in water than the neutral sulphate, and crystallises in prisms or plates.

A *sesquisulphate of potash* ($2(KO, SO_3)+HO, SO_3$) also exists.

Hypochlorite of potash, chloride of potash, or *chlorinated solution of potash* ($KO, ClO + K, Cl$ for $2(KO, Cl) = KCl + KO, ClO$). Obtained on passing chlorine into solution of potash. It is a disinfectant; but the corresponding soda-salt is more generally used.

Chlorate of potash (KO, ClO_5), *oxymuriate of potash*, is formed on passing chlorine gas into a mixture of 69 parts of carbonate of potash with the slaked lime that is obtained from 168 parts of quick lime. The resulting mass is lixiviated with water, and evaporated till the chlorate crystallises out. The decomposition is thus expressed :—

$$\underbrace{KO, CO_2}_{\text{Carbonate of potash.}} + \underbrace{5(CaO, HO)}_{\text{Hydrate of lime.}} + \underbrace{Cl_6}_{\text{Chlorine.}} = \underbrace{KO, ClO_5}_{\text{Chlorate of potash.}} + \underbrace{5CaCl}_{\text{Chloride of calcium.}} + \underbrace{5HO}_{\text{Water.}} + \underbrace{CO_2}_{\text{Carbonic acid.}}$$

Chlorate of potash is soluble in 16 parts of cold water, but in less than twice its weight of boiling water. It has a cooling saline taste. When heated, it parts with the whole of its oxygen. [OXYGEN.] It is a powerful oxidising agent, and is used in certain operations connected with calico-printing and in the manufacture of lucifer matches.

Perchlorate of potash (KO, ClO_7) is obtained, as already described [CHLORINE, *Perchloric Acid*], in small crystals derived from the octohedron.

Nitrite of potash (KO, NO_3). [NITROGEN.]

Nitrate of potash (KO, NO_5). *Nitre. Saltpetre.* This important salt occurs native, as already described. Nearly all the nitre used in this country comes from the East Indies. The soil in the neighbourhood of Tirhût, one of the most productive districts, contains on the average about 7 parts of nitrate of potash and rather more nitrate of lime in 1000 parts. The solution of these salts, brought to the surface of the ground by capillary action, is rapidly dried by the wind and sun, and the salts remain behind as a frost-like efflorescence. The natives scrape up the deposit from time to time, mix it with carbonate of potash in the shape of solution of wood-ashes, and evaporate the solution to dryness. The use of the carbonate of potash is to decompose the nitrate of lime, carbonate of lime being precipitated and nitrate of potash remaining in solution along with that originally present. After a second solution and crystallisation, it is sent into commerce, though still impure.

The analysis of crude nitrate of potash, or the estimation of the amount of real salt contained in it, is technically termed the *refraction of nitre*. Many processes have been devised for the accomplishment of this object, but each requires modification according to the variety and apparent amount of the impurities. They are all more or less based upon the ordinary method adopted in general chemical analysis. Frequently, the only required information is the amount of nitric acid contained in a sample. To this end, about 10 grains are weighed into a porcelain crucible, then fused to drive off water, cooled, a weighed quantity of sulphate of lead added, the whole re-ignited till no more fumes are evolved, and again weighed. The loss sustained during the second heating is due to nitric acid; for nitrate of potash—and indeed other nitrates—are decomposed when heated with sulphate of lead, sulphate of potash and oxide of lead remaining, while the whole of the nitric acid is given off as peroxide of nitrogen and oxygen.

In many parts of the continent of Europe, the nitrogen in every description of refuse animal and vegetable matter is converted into the form of nitric acid, and thence into nitrate of potash, by exposing heaps of offal, mixed with old mortar, slaked lime, chalk, and earth, to the free action of the air, but protected from the rain; the whole being occasionally watered with stale urine, stable runnings, &c. Great care and skill is often bestowed upon these *saltpetre beds* or *nitre plantations*, as they are called, and after two or three years' exposure, the end first formed is lixiviated with water and treated as before described for obtaining nitrate of potash. In the above putrefactive process of *nitrification*, the nitrogen, as usual, first takes the form of ammonia, and this in the presence of the lime is gradually oxidised by the air to nitric acid: a temperature below 60° Fahr. prevents this action.

The chief use of nitre is in the manufacture of GUNPOWDER. It is to some extent employed in medicine, and when fused and cast into cakes or bullets is frequently called *Sal Prunella*.

Chromates of potash. The *neutral* salt (KO, CrO_3) is formed on neutralising the bichromate with carbonate of potash. By evaporating the solution it may be obtained in transparent yellow prisms. The *bichromate* ($KO, 2CrO_3$) is obtained directly from ground chrome iron ore, by fusion with carbonate of potash and nitre. The resulting mass is digested in water, the liquid saturated with nitric acid and evaporated to the crystallising point. Bichromate of potash crystallises in large ruby red four-sided tables. Its chief value depends upon the chromic acid it contains. See CHROMIUM, and LEAD, *Chromates of*. A *terchromate of potash* ($KO, 3CrO_3$) also exists.

Acetates of potash. [ACETATE.]

Tartrates of potash. [TARTARIC ACID.]

Oxalates of potash. [OXALIC ACID.]

Cyanide of potassium (KCy). Formed by fusing together eight parts of anhydrous ferrocyanide of potassium, three of dried carbonate of potash, and one and a half of charcoal. The resulting mass is digested in water, filtered or decanted, and evaporated to dryness. From solution in alcohol it crystallises in colourless cubes. It is used for forming and dissolving the cyanides of gold and silver in electro-gilding and plating, and in photography. It is a powerful reducing agent, and is exceedingly poisonous. It forms double salts with other cyanides. [CYANOGEN.]

Ferrocyanide of potassium ($K_2Fcy+2Aq.$) *Yellow prussiate of potash*. This salt is prepared by heating together, in a covered iron pot, a mixture of about five parts of horn parings, hide clippings, horse's hoofs or other similar refuse animal matter, with about two parts of pearlash, and a quantity of scrap iron. At the high temperature employed the nitrogen and carbon combine to form cyanogen, and this, with the iron and potassium of the pearlash, forms ferrocyanide of potassium. On digesting the cooled mass in water and evaporating the solution, the salt crystallises out in large yellow crystals derived from the octohedron.

Ferridcyanide of potassium (K_3Fdcy). *Red prussiate of potash*. This salt is formed on passing chlorine through a dilute solution of the ferrocyanide, till the latter ceases to give a blue precipitate with a persalt of iron. On evaporation and recrystallisation magnificent ruby red prisms are obtained. For the relative composition, probable constitution, and uses of ferrocyanide and ferridcyanide of potassium see CYANOGEN; FERRIDCYANIC ACID; FERROCYANIC ACID; METALS, *Iron, ferrocyanogen* and *ferridcyanogen*; BLUE, *prussian blue*.

Sulphocyanide of potassium. See CYANOGEN.

Potassium-amide $\left(\left.\begin{matrix}K\\H\\H\end{matrix}\right\}N\right)$ is a primary inorganic monamide, formed on gently heating potassium in a current of dry ammoniacal gas; hydrogen is at the same time evolved. It is a fusible, semi-crystalline olive-green compound. Heated to redness it is decomposed, a greenish-black infusible body remaining, which is the corresponding tertiary monamide, or *nitride of potassium* $\left(\left.\begin{matrix}K\\K\\K\end{matrix}\right\}N\right)$.

Detection of potassium. The salts of potassium are characterised, first, by communicating a purple colour to the blowpipe flame; second, by affording a crystalline precipitate on being mixed with excess of a saturated solution of bitartrate of soda—this test may not succeed if the potassium be present only in small quantity; third, by giving a yellow granular precipitate on the addition of bichloride of platinum.

Estimation of potassium. This is usually effected in the state of the double chloride of potassium and platinum just mentioned ($KCl, PtCl_2$). The substance—from which all other metals have been separated by the ordinary system of analysis—is acidulated with hydrochloric acid, the bichloride of platinum added, and the whole evaporated to dryness. The residue is then washed with a mixture of alcohol and ether, and weighed on a tared filter; 100 parts are equivalent to 15·98 of potassium, or 19·26 of potash (KO).

POTASSIUM, OXIDE OF, POTASSA or POTASH, *Medical Properties of.* The preparations of potash which are used in medicine are very numerous; but they may be reduced and spoken of under a very few heads:—First, those which are employed from their causticity to produce counter-irritation, or to open abscesses: these are hydrate of potash (potassa fusa) and potash with lime (potassa cum calce), which have been already treated of. [ESCHAROTICS.] Second, those which are employed to counteract acidity, namely, liquor potassæ, carbonate and bicarbonate of potash, the alkalinity of which last two is diminished in proportion to the increase of the carbonic acid combined with the alkali. Thirdly, those which possess a purgative property, such as the sulphate and bisulphate of potash, the tartrate and bitartrate. Fourthly, those possessed of a diuretic property, such as the acetate, and, when in small doses, the tartrate, bitartrate, the nitrate and chlorate of potash. Besides these, there are the sulphide of potassium, the bromide of potassium, and iodide of potassium, which possess special and characteristic qualities, which prevent their being classed with any of the preceding. Chlorate of potash is of great utility in the treatment of diphtheria.

The various uses of which these numerous preparations are susceptible can only be explained in medical treatises: all that is proper here is to caution individuals against the employment of those which counteract acidity. These are extensively had recourse to, either in a simple state or as ingredients in effervescing mixtures, for the cooling effect they produce, or designedly to remove superfluous acid in the stomach. Where much debility exists, and more particularly if the phosphatic diathesis, or disposition to the deposit of the phosphates from the urine, be present, a single dose of such articles may do much injury, and their frequent or prolonged use creates a worse condition than that which they were intended to remedy. But this does not preclude the employment of a solution of carbonate of potash to induce a coating of phosphates over the sharp angles of the mulberry or oxalate of lime calculus. [OXALIC ACID.] An intelligent medical attendant can alone decide on their propriety. "If I were required," says Dr. Prout, "to name the medicine calculated to do the most mischief, I should name the common saline draught formed of potash or soda and some vegetable acid." ('Treatise on Diseases of the Urinary Organs,' 2nd edition, p. 145.) [CARBONIC ACID.] This remark equally applies to many of the popular summer beverages, such as imperial; and many effervescing drinks prepared with lemon and kali.

The property assigned to bromide of potassium, of removing enlargements of the spleen, is by no means clearly proved. The powers of iodide of potassium have been noticed under IODINE, and those of the sulphide of potassium are treated of under SULPHUR. In case of poisoning by liquor potassæ or the carbonates, vegetable acids or oils should be instantly administered.

POTASSIUMAMIDE. [POTASSIUM.]

POTASSIUMETHYL. [ORGANO-METALLIC BODIES.]

POTATO (*Solanum tuberosum*, Lin.). The circumstances which led to the introduction of this valuable vegetable into the system of British husbandry may be thus succinctly stated:—

Queen Elizabeth, in 1584, granted a patent "for discovering and planting new countries not possessed by Christians;" and under this sanction some ships, principally equipped by Sir Walter Raleigh, sailed with him to America. Thomas Harriott (afterwards known as a mathematician), who accompanied the adventurous squadron, transmitted to England the description of a plant called *Openauk* by the natives of that part of North America which the courtier-like gallantry of Raleigh had named Virginia.

Harriott described the *Openauk* as having the roots round, and "hanging together as if fixed on ropes, and good for food, either boiled or roasted." Gerarde, in his 'Herbal,' a few years subsequently, distinguished the plant by a plate; and not only confirmed the assertion that it was an indigenous production of Virginia, whence he himself had obtained it, but supplied some curious details of its qualities, and of the various modes in which it may be dressed for the table. He especially recommended it as the basis of "delicate conserves and restorative sweetmeats," with the assurance that its flatulent effects may be infallibly corrected by having the roots "eaten sopped in wine;" adding, "to give them the greater grace in eating, they should be boiled with prunes."

The honour of first cultivating the potato in Ireland, where it has so long constituted the principal food of the peasantry, has been attributed to the grandfather of Sir Robert Southwell, president of the Royal Society of London, towards the close of the 17th century. Sir Robert's statement was to the effect that his ancestor had obtained some roots from Sir Walter Raleigh.

But the potato had been known in Spain and Portugal at an earlier period, and it is from the latter country that we most directly derive the name by which we know it: this is easily shown. Although the natives of North America called our plant openawk, those of the south, more particularly the inhabitants of the mountains of Quito, called it papas, which the Spaniards corrupted into battata: this again their neighbours in Portugal softened into ba-ta-ta (da terra), to which po-ta-to is a very close approximation.

The potato was cultivated in Ireland long before its introduction into Lancashire, which was owing to a shipwreck, it is said, at North Meols, at the mouth of the Ribble, where the mode of propagation still maintains pre-eminence, and whence the culture of this important plant has gradually spread through every portion of Great Britain.

It was not, however, until after a considerable time that it became palatable, productive, and farinaceous, or admitted into the course of field husbandry. It was limited to the garden for at least a century and a half after it was first planted at Youghal, and it was not until 1732 cultivated as a field crop in Scotland. It appears (from the 'General Report of Scotland') that in the year 1725-6 the few potato plants then existing in gardens about Edinburgh were left in the same spot of ground from year to year, as recommended by Evelyn: a few tubers were perhaps removed for use in the autumn, and the parent plants were well covered with litter, to save them from the winter's frost.

Though the plant may be propagated both by its seed and tubers, practical management has confined the cultivation to the latter mode, except for the purpose of raising new varieties or renewing old ones. Those who are curious about varieties (which are now innumerable), can almost indefinitely pursue their object; for the seed of a species, the red apple for example, will sport, and this too without hybridising (that is, without the admixture of its seed with that of any other species, the produce of which would be hybrids), into numberless varieties of form and colour—round, flat, oblong, red, pink, black, white, mixed, and purple, of every shade and colour. These, whether hybrids or not, are reproduced through successive seasons by the tubers alone, if they possess those qualities which render them desirable for continued cultivation, on account of peculiar adaptation to early or late seasons, size, predominance of farina, &c.[*]

This mode of propagation by tubers either improves those qualities, or gradually developes objectionable properties. Some varieties are therefore permanently established, while the culture of others is either abandoned, or, if continued, it is known that those varieties revert in the course of a few generations to the nature of their parent kind, and therefore cease to constitute a variety.

In the vegetable kingdom, hybrid plants have not the power of propagation by seed; but they can be rendered reproductive by budding and grafting, or by means of cuttings, slips, and tubers, and an original stock comparatively worthless may be highly improved by such modes of multiplication. But when a farmer possesses two or three kinds of decided excellence, he will act wisely by not encumbering his stores with too many varieties, which always occasion trouble and confusion in the field management.

In order to obtain seed, properly so called, the potato-apple, when perfectly ripe, should be dried, and then disengaged from its seed by rubbing with the hand. The seed should be preserved in a dry place, in paper or cloth bags, until the beginning of March or middle of April, when it may be sown in wooden boxes or earthen pans, with a covering of less than half an inch of well pulverised earth. The vessels ought then to be placed in hotbeds of mild heat, such as is suited to the raising of half hardy annuals. The plants, when an inch high, should be pricked out into other vessels, and placed in a temperature somewhat lower than before, to inure them to the external air, to which they should be exposed after frosts have ceased. These plants should be put out in drills sixteen inches apart, and with the interval of six inches between the plants in the rows. They will produce tubers in the first year, and these may be planted in the following season in the ordinary way.

For very early crops, such as those which the ash-leaved and walnut-leaved kinds in particular yield, the most successful treatment was that practised by the late Mr. Knight, president of the London Horticultural Society, from the course of whose practice we give the following details of instruction:—Drills may be formed in a warm and sheltered situation (and in the direction of north and south) during any of the winter months, two feet apart, and seven or eight inches deep. Stable dung, half decomposed, should be laid in the drills and combined with the earth four inches downwards, and covered with some of the mould, which had been thrown out in forming the drills, by the rake, to within four inches of the surface. The sets uncut are then to be placed, with the crown eye uppermost, in the centre of the furrow, four inches from each other, and to be covered with only an inch of mould at first, and afterwards with an occasional quantity of sifted ashes, until the plants are so vigorous and advanced as to require the usual earthing, of which, however, very little is necessary. Mr. Knight used leaves as a lining at the sides of the drills in the early periods, to preserve as much warmth as possible, and better to guard against the effects of frost.

---

[*] M. Sargeret, a distinguished and accurate French experimentalist, referred to in the 'Dictionnaire d'Agriculture,' found that out of 800 varieties he had only one exactly like the original from which they were raised; and out of this great number he only found three worth perpetuating.

This management alone will be found successful, except perhaps in very tenacious clay soil, in which the rains of winter may lodge so near the fibres of the plants as to destroy them altogether; but destruction from this cause may easily be avoided by increasing the original depth of the furrows and loosening the bed of clay below with the spade to such a depth as will allow the water to descend from the surface, with a drain to carry it off altogether; or by laying below some absorbent matter, such as ashes, chalk, or calcareous gravel.

The germination of the sets may be accelerated by a little management previously to their being planted, by laying them on a floor, sprinkling them with water until they bud, and then covering them with finely-sifted mould. If this be done in December or early in January, the sets, with strong shoots, may be taken up in February (with as much earth as possible adhering to them), and carefully placed in the drills prepared as directed, and covered with well-rotted leaves or earth in the same way.

To market-gardeners it is a great object to raise the earliest potatoes, considering the high price which they obtain for them, though in their waxy state they are neither wholesome nor palatable. Next in early maturity to the ash-leaved and walnut-leaved are the early Manly and early Champion and Fox's seedling.

The best soil for potatoes generally is that which is altogether fresh from the state of lea, or which has not long been broken up: land which has been in grass for only two or three years is easily prepared for the principal crop. It should be as deeply ploughed as possible before winter, and early in March harrowed, and thoroughly cross-ploughed. After lying in this state for two or three weeks, it should again be well harrowed and very deeply ploughed twice, without bringing up any bad substratum, and it will then be fit for the reception of the crop.

The most approved modes of setting are as follows:—Drills should be formed in the well-pulverised field with double boutings of the plough, in order to have the shoulders uniform, which is essential to the correctness of succeeding operations. The dung is then to be carted out, and divided by the carter with a drag-fork as his horse and cart move forwards (the horse walking in the centre of three drills while the wheels move in the other two), in such quantities as can be most conveniently shaken out into the drills by the labourers employed to spread it. In dry weather the carting does no injury, and this method is universal in Scotland. The other principal mode, more generally pursued in Ireland by some of the best cultivators of the potato, is to cart out the manure before the drills are formed, in rows seven or eight yards apart, and to supply the drills from the heaps as the plough advances in its work, reserving just as much as is supposed sufficient for the concluding drills, which are to be made in the sections of the field previously occupied by the rows of manure. By the latter treatment the manure may be laid over the sets—which cannot be done in the former case—and this will preserve them from being displaced or crushed by the feet of the horses during the process of covering the seed. But against this advantage—which is not inconsiderable—there is the inconvenience of calculating with precision and laying aside as the plough advances to draw the last drills—where the rows had stood—the precise complement of manure, and the difficulty to the ploughman of preserving the exact breadth in those drills.

Some avoid any perplexities in those respects by ploughing in the manure thoroughly before drilling, and either dropping the set in every third furrow, or rolling the whole manured and ploughed surface, and then making drills. Our own experience is greatly in favour of this latter mode, when the fertilising matter is abundant and of the short description which freely combines with the soil, and does not obstruct the plough in the subsequent drilling. The lazy-bed method is so generally condemned, that any explanation of it here would be superfluous, yet in undrained bog-land, or under any circumstances in which a redundancy of wetness is probable in the autumn, as on low marshy lands, or stiff clay soils which have no sufficient inclination to carry off the water, and are likely to be saturated with moisture in winter from want of drainage, the lazy-bed system is by far the safest. The deep wide furrows at each side carry off the water, or at least remove it from the potato. Thousands of tons of potatoes in the year 1839 were utterly lost in Ireland, being drilled in flat and tenacious lands, which would have escaped destruction from the continued rains of that season if drained by the furrow of the lazy-bed. Besides, where circumstances preclude the practicability of deep ploughing, the lazy-bed practice repeated for three years will completely spade-trench the entire land, and thus effect an important benefit not otherwise attainable by the humble tiller of the soil who has no teams for ploughing it effectually. Thus local or national modes, though apparently defective to the superficial observer, are sometimes founded upon sound principles, and though we feel disposed to exclude the minute details of what is only defensible under peculiar circumstances from an essay on potato culture under our modern system, we protest against the unqualified condemnation of a method which is still pursued throughout a great part of Ireland.

The sets (uncut, for reasons to be yet assigned) are next to be laid down, either under or over the manure, at the average distance of sixteen inches, by the setters, who move in a retrograde direction, and are provided with aprons to contain the sets. A sufficient number of men are in attendance to divide the manure evenly in the drills; the plough also is in the field in order that there may be the least possible exposure of the manure and sets to the sun or to parching wind, but the plough should cover the sets rather lightly in clay soil.

The roller is next used to lay an even surface to the brairding* plants, and to facilitate the subsequent progress of the paring plough, which is to be set to work when the stems are six or seven inches high, and should move as close to the plants as is practicable without injuring their tender fibres. The weeders should then hoe the plants carefully, and immediately afterwards (for the influence of wind or hot air on the roots is pernicious) the scuffler or drill-harrow is to follow, in order to clean and level the intervals, before the earthing plough, with either double or single mould-board, is introduced to apply fresh earth to the stems.

Such is the method of earthing universally pursued by the farmer in Ireland and Scotland, but in England the hand-hoe is principally used for destroying weeds, loosening the earth, and moulding the plants; for the two first of these operations the bean-hoe (which cuts about six inches deep) is used, and the turnip-hoe for drawing the earth to the stems. One man will hoe out the weeds and loosen the soil of half an acre per day, and the subsequent earthing of the same quantity is also executed by one man. This is far cheaper than horse-work, and it does no injury to any of the stems, and makes no waste land at the headriggs; and where the earth has been perfectly well prepared at the commencement, this manual husbandry is the best.

As to the distance between the drills, due regard must be had to the natural quality of the soil and the quantity and description of manure available, or in other words, to the probable luxuriance of foliage. Mr. Knight, aware of the necessity of allowing room in proportion to the vigour and height of the plants, has laid down an exact rule thus:—"The height of the stems being three feet, the rows ought to be four feet apart:" but for a general average, thirty inches is the best distance. As to excess of foliage, we are certain that it is not desirable, for the produce of tubers is not always in proportion to the degree of foliage; under high and rank stems there is often a very scanty crop, and Mr. Knight is justified by experience in his observation that "the largest produce will be obtained from varieties of rather early habits and rather low stature, there being in very tall plants much time lost in conveying the nutriment from the soil to the leaves," and consequently strong and upright stems, which do not fall down and shade the others, are those which are desirable.

Two more earthings are usually given, but it is questionable whether even one be necessary in soil of average depth, unless there be a very wide interval between the drills, and it is certain that much earthing in dry and shallow soil is injurious; for by withdrawing the earth from contiguity to the fibres which ramify and penetrate far in loose soil, and laying it on the head of the drill, and in the high ridgelet form, it is applied where it is useless for the nourishment of the tubers, and in a position that favours the rapid escape of moisture, which in such soil it ought to be an object to retain. In deep land, more particularly if it be of tenacious quality, the furrows at each side of the drill will be in general seasons most serviceable as drains, as well as for furnishing earth to support the stems, while the moisture will be sufficiently retained for the roots.

Experiments† have led to the inference that in soil of a loose porous quality there is probably a greater produce by not affording any (or a very slight) moulding, but by digging instead between the rows; for deep and perfect pulverisation, next to an adequate allowance of rich manure, is the main cause of a large produce. In proportion to the deficiency of manure will be the necessity for opening the soil beneath, to allow the fibres, which may be distinctly traced to a depth incredible to those who have not followed their ramifications, to extract all the nourishment which the subsoil may afford. If there be an abundance of nutriment above, neither the necessity nor perhaps the inclination for penetrating deeply can exist, and in such cases the operation of earthing by the plough, as long as it can be introduced without injury to the stems, may be useful in many ways, but unquestionably by guarding them from the effects of storm in exposed, and from excessive wetness in low situations. Besides, in regulating this point, regard should always be had to the quality of the potato, for the tubers of some varieties have a tendency to push to the surface, while others tend into the earth, and therefore require a different treatment.

But in all cases the earth should be rendered as loose and friable as possible, by spade, hoe,‡ or plough; and where labour is easily commanded, the spade will be found to be the more efficacious implement in the first course of treatment after the plants are well up.

---

* A Scotch term signifying "shooting out."

† See Martin Doyle's 'Cyclopædia of Practical Husbandry,' p. 372.

‡ That kind called the bean-hoe, shaped like an adze.

Some plant one or two sets in the centre of every square yard, but in such cases great and continued earthing, until each square presents the form of a pyramid, is contemplated; and, if our preceding remarks be correct, this treatment is only applicable to deep and retentive soils. Great returns have no doubt been thus obtained, but by this mode there is the least possible incorporation of the manure with the soil.

In minute husbandry, such as that exemplified in labourers' allotments, which excludes the plough altogether, the ordinary and best practice is to lay the sets in rows, after a very deep winter digging, marked with a garden-line. The workman digs precisely as in a garden-plot for cabbages: he clears a little drill, lays the sets straight, puts a sufficiency of manure over them, and then covers from the next spit, which he digs with a spade or a three-pronged fork flattened at the ends, levelling and pulverising as he advances to the distance at which he again puts down his line and forms a new drill. Thus the entire piece is thoroughly loosened, the manure perfectly covered, and every facility given for the hand-hoeing in due course.

The next stage of the potato is that in which it blossoms. It has been recommended to pluck off the flowers. Excessive blossoming is no doubt injurious, but experience has generally proved that the extra cost is hardly defrayed by the additional produce obtained. If the flowers are plucked off, they should be nipped in the early bud.

When the crop is fully ripe, which is indicated by the withering of the stalks, and when the land is free from stones, labourers, in the proportion of about twenty to one plough (half of these being usually men, and the remainder women or young persons), should be set to pull up the stalks, and carefully collect the tubers which may be attached to them, before the plough proceeds in its operation. When it is prepared for work, the men, with prongs flattened at the extremity, are placed at such distances from each other as will give them proper time to fork out the potatoes cleanly for the pickers, who are also stationed at exact distances with a basket between every pair, into which they gather the potatoes.

The common swing-plough may be employed in three ways:—First, in taking off a slice from each side of every drill, and leaving it to the workmen to open out the centre with their prongs; or in its third movement it may turn up this centre, under which the main body of the tubers lie, which is more expeditiously and easily done if the earth be in fit condition. Second, a double mould-board plough with a long sack, and divested of its coulter, may be drawn by two strong horses through the centre of the drills, and completely under the level of the tubers, so as to avoid injuring them, by which means the work-people will be kept exceedingly busy; and if the land be in good friable order, this is the most expeditious mode, and, providing there is a perfect harrowing afterwards, the crop will be taken out with sufficient cleanliness. Third, the crop may be taken up by prongs or long narrow spades without the plough. In wet weather this more tedious but far safer method is frequently adopted, and if the drills be short and the headriggs under crop also, it is the most desirable, effectual, and economical mode. In removing the produce in this manner, it is obvious that the number of gatherers should be much less in proportion to the men than under the other circumstances. The headriggs should evidently be the first parts of the field cleared, to make a free space for the ploughs in the boutings, and for the carts.

One horse will answer for three carts if the distance of draught to the pits be short, by changing him alternately from an empty to a full one; but this only applies to the Scotch and Irish system of draught by single carts and horses. The general mode of securing the crops in pits in the field is the safest. In making the pits—improperly so termed, for the base is only sunk a few inches, and the potatoes are raised considerably in the heaps—the only caution to be observed is that furrows should be cut on all sides to prevent water from lodging or penetrating inwards, and that the earth thrown up and over them, to the depth of four or five inches, should be well beaten with spade or shovel to exclude moisture and frost. The potato-stalks, however apparently dry, should never be laid between the potatoes and the earth in these accumulations, for they soon ferment and rot, and injure all the potatoes in contact with them. Straw is at least useless. The length of the pit depends on circumstances, but the breadth should not exceed four feet, as large accumulations are most liable to fermentations.

Of late years the potato has been extremely subject to disease, which first became apparent generally in 1845-6, when the whole crop in Ireland, the mainstay of the people's food, was lost, and a famine ensued. Since that, the same disease has annually reappeared, blackening the leaves before they become naturally ripe, and rotting the tubers either in the ground or in the heap: so that one-tenth to one-half the crop is lost. The only apparent means of remedying this attack, or diminishing its virulence, is by early planting early sorts in early places, so as to obtain a ripe crop before the time (July and August) when the disease generally shows itself. It is also said to be a palliative of this disease, if not a remedy for it, when, by earthing up the nearly ripened crop, the tubers are covered with at least three inches deep of earth, before the period of attack. Besides this disease, there is "the curl," which is an imperfect formation, and was first generally observed in 1764, when it gave rise to various conjectures and unprofitable discussions: the cause is yet unknown. One thing however is clear, that from a crop of which any part is intended for seed, all the plants affected with curl should be carefully separated before the general removal commences. The dry rot, or decay of the set, which during recent years so fearfully prevailed in many parts of the United Kingdom, is also still unexplained as to its real cause, though the press has teemed with essays and very plausible theories respecting it. The set, though apparently sound when planted, has either failed to germinate at all and rotted away, or has feebly and partially thrown out its sickly shoots. The most contradictory causes have been assigned: over-ripening in the preceding year; under-ripening: fermentation in the pits; fermentation of the set in the ground when placed in contact with hot dung (which is utterly absurd, for when in the ground no injurious fermentation can arise); very hot weather, great drought, hot sun, cold parching wind, dry and heating manure, sea-ware, which is always damp; exhaustion of the kind from a long course of culture, contradicted by many instances in which it appears that the produce of the same variety—for instance the apple—has been successfully cultivated during sixty-five years without any failure; or the loss of vitality from prematurely shooting.

If potatoes have fermented in their accumulated state, they would bear obvious evidence of it, and therefore be rejected. Fermentation cannot be the true cause in every or even the majority of cases, nor does the failure probably proceed from insects in the eyes, as has been suggested, for if so, it is difficult to account for the fact that sets from the same heap planted at one part of the day have totally failed, while others put into the ground at another have pushed forth healthy shoots. As to decay in the land from the contiguity of fermenting manure, "How is it to be proved that the gases evolved by fermenting manure can injure the sets? Fermenting manures would rather stimulate by their warmth, and excite their growth by the aliment which their essential qualities, carbon and ammonia, supply to plants. Why do not the gaseous exhalations from rank and fermenting hot-beds destroy the tender plants which are raised in them?" (Doyle's 'Cyclopædia of Practical Husbandry.')

A partial remedy for dry rot is to be found in the planting of entire tubers. When the cut sets have failed, the entire tubers have resisted premature decay; whether it arises from atmospheric influence, or debility of constitution, or from any of the conjectured causes, the entire tubers resist these noxious influences, and germinate healthily and freely. All reports agree on this point: there is no risk in this case, if the tubers be sound when planted; and it may be added, that in all stages of their growth, the uncut tubers maintain a decided superiority, and yield a corresponding produce.

The farina of the potato, properly granulated and dried, is sold in our shops as arrowroot, or mixed with gum as tapioca, to which it bears the closest resemblance, both in appearance and essential properties. For confectionary the flour is so delicately white, and it is so digestible and nutritious, that it ought to be in more general use, among the children of the poor especially, in the winter season, when they so rarely enjoy the luxury of milk; and the cost is not more than a sixth or seventh of the price of tapioca or arrowroot, if it be made at home. Few housewives are ignorant of the method of obtaining it by the use of a common hand-grater and sieve; but for yielding larger supplies some machinery is necessary.

POTIN, a name given by numismatists to an alloy of brass and other metals, from a French word signifying pot-metal. The term is generally applied to a base metal substituted in the ancient currency for silver, consisting of brass, lead, and tin, with an admixture of a fifth part of silver; the presence of tin constitutes potin, as without this metal the alloy is called *billon*. The coins of the Roman emperors minted in Egypt, some of the early coins of Gaul and Britain, and of the later days of the Roman Empire, are in this metal. [NUMISMATICS.]

POTTERY. The word pottery, derived from the French *poterie*, the Latin *poterium*, and the Greek *potérion*, or drinking-vessel, has been applied to all descriptions of dried or baked clay. The worker or manufacturer is styled potter, and the place or establishment where made, pottery; besides which, the term ceramic, from the Greek word signifying earthenware, and fictile from the Latin, has been applied to objects produced in baked or dried clay. The art of working in clay is of such high antiquity that it appears long prior to the historic period of the human race, and was attributed by all nations to gods or mythical personages. In Egypt, the cradle of the earliest arts and sciences, this art is attributed to god Chnum, and its early invention is proved by the bricks of sun-dried clay, of which some of the oldest pyramids were built [PYRAMID]; the vases of red earthenware found in contemporary sepulchres of the 4th or 5th dynasty, and the representation of potters engaged at their occupation on the wall paintings of tombs of the 4th and 12th dynasties. The brick, the oldest of all pottery, called by the Egyptians *teb*, or "box," and at the earliest period made of sun-dried clay mixed with straw, fragments of red pottery, and other materials, was of the shape of those at present, but of larger proportions, about 5 inches thick, 8 inches wide, and 18 inches long, stamped out of a mould, and impressed, from the commencement of the 18th dynasty, with the names of monarchs, constructions, and other inscriptions, made by a wooden block on its upper surface. Such bricks were extensively used for pyramids, walls, tombs, and other constructions. The early invention of the wheel, and the manufacture of vases, bricks, and other objects of red earthenware in Egypt, are proved by the remains and wall paintings. The wheel was a small circular table placed horizontally, which the potter turned with his hands, not feet, at the earlier period, and produced vases of dark-red earthenware, either polished or dull, of various and simple shapes, and sometimes of large dimensions, applicable for all purposes, and often gaily painted all over with a coating of clay or lime to imitate valuable stones, or ornamented with zones or wreaths and other plain ornaments, or inscribed with names and other inscriptions. Besides this process the Egyptians moulded vases of red ware in the shape of men and animals, and modelled coffins and other large objects. Under the Roman empire figures of gods and lamps were moulded in Egypt, and fragments of pottery were used for receipts and inscriptions till the 6th or 7th century, A.D. But the most remarkable Egyptian pottery was the *porcelain*, or rather fayence, the body composed of a white or gray sand, and the surface covered with a siliceous glaze, often $\frac{1}{12}$th of an inch thick, coloured with the oxides of copper, manganese, silver, and tin. The objects of this material were of small size and generally moulded, and consisted of small tiles, and portions used for inlaying vases, beads, bugles, little figures of deities, and sepulchral figures [Mummy], principally in a blue of different shades, but of remarkable beauty. Under the 19th and subsequent dynasties, the blue gave place to a green porcelain of inferior quality. At the earlier period the art of glazing steatite with this glaze was introduced. The Egyptians appear to have invented this porcelain and retained the secret, small objects in these materials having been found in Greece, the Isles of the Archipelago, and Italy, apparently exported from the ports of Egypt. The manufacture was continued under the Greeks and Romans, but gradually disappeared at the beginning of the Empire, a few vases and lamps of it having been found in Italy of Greek form, and with Greek subjects in relief, probably made at Alexandria; it seems to have been superseded by metallic and glass work.

The Assyrians like the Egyptians made extensive use of sun and kiln-dried bricks, especially for the substructure of their edifices, walls, houses, and tombs; their bricks were of another size, about 14 inches square by 4 inches thick. Like the Egyptian their upper surface is often stamped with the names and titles of their king in Assyrian cuneiform. The Assyrian potter was also extensively engaged in producing in clay histories, title-deeds, religious dedications and other documents on hexagonal prisms, cylindrical rolls, and small square slabs convex on both sides. On these the inscribed letters were impressed from a small punch. Many of these were impressed with seals, and even seals of baked clay added to deeds. About 10,000 fragments of an ancient terra cotta library were found in the archive room of the palace at Kouÿunjik, and the preservation of the history of Sennacherib and his campaign against Judæa, as recorded in the Assyrian annals, is owing to this indestructible method of preserving public records. Like the Egyptians the Assyrians, in the 8th or 9th century, B.C., were acquainted with the art of making a fayence or enamelled ware with metallic oxides and tin and lead fluxes; and the story of Semiramis and her constructions with glazed bricks, representing subjects, is by no means fabulous. The vases and other objects of this material differ considerably in their body, which is of a yellow paste, from the Egyptian, and the ware is inferior to it in colour and elegance. The potter's art seems to have been in full activity till the fall of Nineveh, and to have been kept up till a late period in the plains of Assyria.

The arts of the Babylonians, who were contemporary with or succeeded the Assyrians, are so like that the difference is hardly perceptible. Sun-dried bricks of nearly the same dimensions as the Assyrian, found in all the ruins of the plains of Shinar, were prepared by the same process, and generally had straw. The kiln-dried bricks, mentioned in Genesis as in use after the Flood, have also straw for the sake of heating them more thoroughly, and vary in quality and colour. They are also stamped with the names of Babylonian monarchs. Some buildings, as the Birs Nimrud, now known to be a temple dedicated by Nebuchadnezzar to the seven planets, were made of stages of differently coloured bricks, each the appropriate colour of the planet. Mortar of lime and bitumen for the foundations, as mentioned in the description of the Tower of Babel, is found to have been used for cementing the brick-work together. Small cones were also used for making an ornamental brick-work. The public and private records were preserved in baked clay like the Assyrian, and bas-reliefs and small votive figures of baked and sun dried clay, made by a mould, were used for religious purposes, and portions of the colossal statues of the gods appear to have been made of clay, plated externally with brass, or clay formed part of the figure with other metals. The glazed ware of the Babylonians was of the same character as the Assyrian. The potteries of Assyria and Mesopotamia appear to have continued in activity under the foreign rulers of that country, and the remains show local wares manufactured under Greek and Roman influence, while the use of the fayence under the Sassanian monarchs took an extraordinary development, an immense number of glazed coffins of that period having been found at Warka and Mugeyer, with other fictile remains of a late epoch. The Persians, who succeeded to the empire of the Assyrians, are only known to have used pottery, and the art of pottery must be considered at this period to have been chiefly exercised by the Phœnicians and Greeks. The first of these people, the great traders of antiquity seem to have made plain unglazed terra cotta and glazed ware like the Egyptians, and to have traded in them with the Greek islanders and the Etruscans at about the 7th century, B.C. The Hebrews do not appear to have exercised the art till after the Exodus, and probably brought it with them from Egypt, having before that period used other substances for drinking purposes, or acquired them from other people; and the very few Jewish vases as yet found do not seem older than the Maccabees, although the art of glazing by litharge was known in the days of Solomon. At the time of the Captivity the prophets often used metaphors derived from the potter's art, and some bowls supposed to have been used by the captive Jews of Assyria are evidently of a comparatively recent epoch. Fragments found in Moab have revealed a ware like the earlier glazed Greek; but the greatest advance in the fictile art was made by the Greeks.

Prometheus, according to their legends, had modelled Pandora out of Sinopic clay, and bricks, statues, and other objects of sun-dried clay were made by some of the earliest potters. Kilns were, however, in use at the earliest age, and the palaces of Crœsus, Mausolus, and Attalus show their extensive use in Asia Minor, while constructions of brick have been found at Athens and in Sicily. They were made as the Egyptian by wooden moulds, *plaisia*, and named after the dimensions: *didora* 1 foot long and 2 palms or half a foot broad; *tetradora*, 4 palms square, chiefly in use for private buildings; and *pentadora*, or 5 palms square, used in public edifices; and *Lydia*, or 1 foot 6 inches long 1 foot broad, probably those of the palace of Crœsus. Besides which a very light kind was made at Pitane in Mysia. Bricks of dimensions not described by ancient authors have been also found, and all are distinguished by their greater thinness than the Egyptian or Assyrian ,resembling tiles, and made of a fine red or yellow clay. Till about B.C. 580 the temples of Greece were roofed with terra cotta tiles *keramoi*, which were said to have been invented in Cyprus, and are flanged at both sides like the Roman, the joint being covered with a semicircular tile, and the lower semicircle of the series having an upright semi-oval part called the antefix, on which ornaments were impressed in a bas-relief, the front of the antefix being faced with a finer clay for the impression; all these tiles have occasionally stamped upon them, in relief, the name of the city, the potter, and year of the magistrate in which they were made. The cornices of tombs and *naoi* or shrines of the Doric order were ornamented with gargoile heads of lions, and the invention of antefixes was attributed to the Corinthian potter Dibutades, who flourished at a mythic period. Friezes and other architectural members, and cylindrical pipes of terra cotta for draining or conveying water were also used by the Greeks. One large branch of the manufacture consisted in small figures called *pelina* clays, or *agalmata ostrakina* earthenware, used for penates or votive offerings; they were made in a mould of two pieces of a harder and more compact terra cotta, into which a crust of clay about 1-8th inch thick was pressed so as to leave the centre and base of the little figure hollow, the heads and arms were solid, and sometimes produced from separate moulds and attached.while the clay was moist. At the back there is usually a large hole to allow the clay to expand or to attach the figure to a wall. After coming from the furnace these figures were covered with a coating of whitewash *leukoma*, and then painted and sometimes partially gilded. Some of these figurines are as old as the Dædalids, and they continue till the close of the Roman Empire. Larger figures of deities are of rarer occurrence, and existed in Greece in the days of Pausanias, and others, are mentioned as extant in Constantinople. This art was first applied to producing casts of statues in other materials by Lysistratus, the brother of Lysippus, and by other artists, such as the celebrated Zeuxis, who flourished B.C. 400, to model the subject of his pictures, and Pasiteles, a Greek artist, living at Rome, in the 1st century, B.C., modelled his statues first in terra cotta. Terra cotta was also used for portions of statues in toreutic work and for the moulds of objects in bronze. Reliefs or friezes of different sizes, *emblemata* for applying to other works of art, were also made from moulds and painted in the same way: cones used for the loom, or as weights for nets or drapery, dolls called *koræ*, *nymphæ*, or *neurospasta*, but with moveable hands and arms, and lamps, *lychni*, were made of terra cotta, with reliefs on the upper surface, and the maker's name on the base below.

The invention of the potter's wheel at the earliest period of Greek history described in Homer, claimed by Athens for Corœbus, by Corinth for Hyberbius, and for Dædalus or Talus by the Cretans, probably came from the East. The wheel was a low horizontal table turning on a pivot on a central foot; it was made to revolve by a boy or assistant, and extensively used in the production of vases of various shapes and all dimensions, such as saucers, *phialæ*; plates, *pinakes*; jugs, *œnochoæ*; pots, *chytræ*; boxes, *pyxides*; and even jars, *amphoræ*, in great numbers; and all vases except huge casks, *pithoi*, which were moulded on a frame. The feet and handles of vases were stamped or moulded, and fixed while wet to the body of the vase. The amphoræ of several states, about the 2nd to 1st century B.C., are stamped with the name and emblem of the magistrates on the handle to indicate the state from which they came, and the date when they were made, but they are otherwise not ornamented. [Vases.] Some of the sepulchral vases were covered with a *leukoma*, painted in colours and gilded, but these belong generally to the class of glazed vases. These vases were made of a finely levigated clay, such as has recently been found at Mon

Reale in Sicily, in the vicinity of Naples, and elsewhere; and the most celebrated clays were those of Mount Colias near Athens, Corinth, Cnidus, Samos, and Coptos. The vases were made by the same process as those of terra cotta, but are of a redder or paler clay. After they had been sufficiently dried in the sun they were painted, and the upper surface, to about ⅓rd the thickness of the vase, was faced with a finer clay to receive the colour. The figures intended to be painted were first traced on the wet clay with a tool in a slight outline, or in a dotted line, and the colours laid on with a reed formed like a brush. Some of the colours were glazed and others flat. The principal colours were fawn, maroon colour, and black, which varies from a deep jet to a deep green or leaden hue. This was made of manganese, oxide of iron, or carbonaceous substances. The other colours used, flat and not glazed, were white made of a fine pipe-clay or alumina, crimson produced by an oxide of iron, yellow ochre, blue and green oxides of copper, a light brown ochre, light red made of ground terra cotta, and a bright scarlet produced from an iron oxide. Gilding was occasionally employed, especially on the later vases. The glazed colours were mixed or covered with a siliceous or thin alkaline glaze, and the vases were sent to the furnace and baked at a low temperature, apparently without saggers. Glazed vases of this kind were manufactured in Greece, from the 8th or 9th century till the 1st century B.C., but very different in paste, style, shape, and colouring. The earliest vases contemporaneous with the heroic age of Greece, and found at the oldest sites, are of a pale clay, clumsy shape, generally of large size, and painted in light red, brown, or dark coloured ornaments of large proportions. With these are occasionally very small figures of animals, which by degrees are drawn of larger size, but still of the same thin proportions. These vases, which have no inscription, and were succeeded by others of Corinthian fabric with a pale clay, the body covered with a siliceous coating of a cream or lemon colour, the figures and ornaments painted in a dark brown, maroon, or black colour, the subjects of which were at first friezes of animals, *zoidia* of larger size and fuller proportions, with backgrounds strown with flowers. After they returned from the kiln, the potter cut with a sharp tool incised lines in the dark figures and ornaments to mark out the details and relieve the monotony of the figures, and touched up parts with a flat crimson colour. The later vases of this style have human figures introduced with animals, and *Doric* inscriptions as old as the 6th century B.C., and subjects derived from Asiatic sources, or the oldest legends: some of these vases are supposed to be late imitations, and great difference is observable in the local fabrics of Corinth, the Isles, and Italy. By degrees the potter changed the tone of the clay, introducing a pale salmon-coloured earth, and ceased to use animal friezes except in a subordinate manner; the art also improved, although resembling the Æginæan and Selinuntine remains. By degrees this style attained its full development by the employment of a rich orange red clay, and of a dark black for figures and backgrounds, a freer use of white and red flat colours, a more finished style of art, with figures of better proportions, and the abundant use of inscriptions, giving the names of the figures represented, of the artists, potters, the celebrated beauties of the day, speeches, and exclamations. The attitudes are still, rigid, the eyes seen in profile, the forms full and muscular; the accessories, parts of the form, and of the draperies, are coloured in crimson, and the flesh of females white. There are clearly traces of two or three fabrics in these vases—of earlier ones, the most remarkable is that at Florence, the work of the potter Hergotimos and the artist Glaucythes, representing in several friezes the arguments of an epic poem, reciting the adventures of Achilles. Several artists of this style, such as Amasis, Execias, and Hieron painted with great vigour; the principal shapes are *Hydriæ*, or water vases with three handles, amphoræ with two; *œnochoæ*, or wine jugs; and *cylices*, or cups; other shapes called *cyathi* and *mastoi* are of rarer occurrence. The subjects are chiefly taken from the adventures of Bacchus, the exploits of Hercules, and the war of Troy, the contest of the gods and giants, and of the Greeks and Amazons. These vases seem to have continued until the 5th century, B.C., when a new class of painted vases were invented; the figures were traced out as in the old style, but the back ground was filled in with black colour, and the figures left the rich warm red colour of the clay; the inner details of the form were traced with fine black lines of the same glaze, to which finer lines in a brown glaze indicating those portions less distinctly seen were added; the accessories are at first coloured in crimson, but white was subsequently introduced. The art at first resembles that of the black figures, and some painters used both styles on the same vases; but by degrees, especially after the age of Phidias, B.C. 460, the art rapidly improved; the eyes are no longer oblique but represented as in modern drawing, and lashes are introduced; full faces appear, the drapery of the figures alter, the flesh of the female figures is the same colour as the male. Inscriptions are rare, but the letters of the later and completed alphabet are found. The principal shapes are *amphoræ*, *krateres*, *œnochoæ*, and *cylices*, and some varieties of cups; the *hydriæ* disappear for the smaller *kalpides*, and the amphoræ are of smaller proportions. These vases appear to have been made from 480 to about 360 B.C. Their subjects are taken from the same sources, with the addition of others from the *Nostoi*, or return of the Greeks, the Odyssey, the Oresteid, Perseid, and the Gymnasium. Many of the paintings seem to be copies from memory of the pictures of Polygnotus, Parrhasius, and Zeuxis. As the style continued to improve the figures became larger and more grandiose; and finally, of more slender and elegant proportions, with elaborate dresses and minute and finished lines resembling those of the coins of Magna Græcia and Sicily. In the days of Pyrrhus, an attempt is made at aerial perspective by groups introduced at different heights, and the introduction of undulating lines, stones, and other objects; while interiors are represented, and the pictures, as in modern art, crowded with accessories or mingled with arabesques. Some of these vases exhibit local costumes; the size of the craters, amphoræ, and larger vases transcends that of the last style; the subjects are principally those of the later myths of the Tragedians. Nearly contemporary with these vases are those having their body covered with a *leukoma*, or coating of white, on which figures have been traced in red outline and then painted with polychrome flat colours. They are principally lecythi, and used for the dead. Other vases of this class, of small size, are moulded in shape of gods or animals. The close of the vase art in Greece and Italy appears to be about the 2nd century B.C. The florid style had then degenerated into a coarse scrawl, with subjects taken from the comic stage; and at last the potters substituted moulded vases entirely coloured black with *emblemata* stamped at the handles, or painted with opaque flat colours, masks, arabesques, doves, and heads on the black glaze of the vases; some are accompanied with archaic Latin inscriptions, evidently after the conquest of Campania by the Romans. At all periods there were numerous vases entirely painted black, called *libyes*, of less value than the vases painted with figures, but distinguished by the lustre of their glaze, that of Nola being remarkably black and bright, and at the later period in S. Italy of a leaden hue. In imitation of the metallic vases, which superseded those of clay, the later ones have *emblemata* or bas-reliefs stamped in separate pieces and affixed while the clay was moist, or even stamped with figures in intaglio to imitate cups of precious stone which were engraved like gems. During the most flourishing period of the art the names of about fifty potters and thirty vase painters are known as exercising the art. The trade was lucrative, the prices on the whole being about the same as modern earthenware. These vases have been found in Italy as far north as the ancient Hadria, throughout Greece proper, and Asia Minor, to the Taurus, in the Isles of the Archipelago, and as far east as Panticapæum.

The pottery of the Greeks did not, however, enjoy the entire monopoly of the Italian market, for various kinds of wares were made in the peninsula; in the north, the Etruscans manufactured a red gritty ware distinguished by the presence of micaceous particles of a volcanic sand, and terra cotta of a red colour, into tiles, busts, statues, reliefs, and architectural mouldings. Etruscan statues in clay, called *signa Tuscanica*, were supposed to be of the highest antiquity, and decorated the early temples at Rome. The most celebrated were the statue of Jupiter Capitolinus, made by Vulcanius or Turianus of Fregellæ, or Veii, the quadriga on the acroterium of the temple, the Hercules of the Forum Boarium, and a Janus. Bas-relief friezes, made from moulds, have been found at Velletri and other Etruscan sites; and numerous sarcophagi of terra cotta, generally small, but sometimes of life size, destined to hold the ashes of the dead, and gaudily painted in tempera, and either modelled or moulded, have been discovered in the Etruscan territory. Vases of many shapes in imitation of the Greek, both of glazed and plain wares, were made by the Etruscan potters. The glazed vases, called by the Italian antiquaries national, are of a paler clay, and glazed with a black colour of an ashen or leaden hue, with subjects derived from the Etruscan mythology, accompanied with Etruscan inscriptions.

Besides these vases, the Etruscan and Sabine of the earliest period resemble in paste and texture the Scandinavian and Celtic found distributed over the surface of the European continent, distinguished by rude forms, apparently borrowed from works in wood or metal, and ornamented with studs, knobs, engraved or punctured ornaments. The most remarkable of these vases were those found near the Alban Lake, resembling the ancient *tuguria* with their pent roofs, and containing the ashes of the dead; they were found in 1817, surrounded with smaller vases, and placed inside large two-handled vases for protection, under beds of lava, and were referred to the most remote age. These vases were baked at a low temperature, and modelled as well as turned on the lathe. The black ware of the Etruscans was made of a clay mixed throughout with oxide of iron and manganese, and breaking with a black fracture; polished externally. The walls of the vases are thick in some localities and thin in others; they are ornamented with incised or punctured lines, or ornaments disposed in friezes or bas-reliefs round the body. Besides the ornaments on the body of the vase, the handles, lips, and other parts are fantastically decorated with relief ornaments, representing men and animals, in a style more ornamental than convenient, and attempting in clay to imitate the metallic work of Asia and Greece; the subjects being chosen from the oldest myths of Greece or Asiatic deities. Many vases are ornamented with friezes of small figures about one inch high made from a cylindrical stamp revolving on the clay. This ware appears to have continued from B.C. 660 to 395, the fall of the Etruscan power. Some examples have Etruscan inscriptions incised upon them, but only the names of possessors. Works of terra cotta have been discovered in other Italian sites, as at Ardea, amidst the Samnites, and at Capua, but there is nothing to distinguish them in type or design from the Hellenic art of Magna Græcia.

The pottery of Rome was probably imported from Etruria, and the earliest ware was the black Etruscan. Numa, indeed, is said to have founded a guild of potters, B.C. 700, but the oldest known Roman vases are saucers or phialæ of red clay, coloured with a leaden black glaze, ornamented with white figures and inscribed in painted white letters *Volcani pocolom*, *Lavernai pocolom*, the cup of Vulcan, the cup of Laverna, &c. These were probably made in Campania, about B.C. 200, after the conquest of Southern Italy by their arms. The old potteries of Rome are by no means distinguishable from their neighbours, and they probably imported Greek, Etruscan, Campanian, and other wares for all but the commonest and roughest usages of life. Old Rome, before the rebuilding of the city by Augustus, who boasted that he had found it of brick and left it of stone, was built of brick houses. The Roman brick was made of the same shape and dimensions, and in the same manner as the Greek, and Vitruvius calls them *Lydia*, *pentadora*, and *tetradora*. The usual dimensions are 15 × 4 inches superficial, and 2 inches thick, and they rather resemble tiles than bricks; but some, in dimensions like the modern bricks, are seen in the Meta Sudans at Rome. The paste of the Roman bricks is of a close, compact, and fine texture, remarkably hard and sonorous when struck, and is of a dark red or straw colour. They often bear traces of the feet of boys in hob-nailed sandals, goats, dogs, and other animals which have walked over them while drying in the kiln, and have inscriptions incised upon them, sometimes alphabets traced by boys, poetic effusions, the dates when prepared, and the purpose for which made. Tiles, *tegulæ*, are distinguished from the bricks by their flanged edges, *hamatæ*, and were made by the same process; they were covered at the joint by a semicircular tile, *imbrex*, the end imbrex of the series terminating over a semi-oval upright, called the *antefixum*, on which was impressed in bas-relief an architectural ornament or figure of a deity; the cornices also of terra cotta had gargoiles in shape of the head or forepart of a lion. The paste of the tiles is similar to that of bricks, but their dimensions differ; they are 1 foot 3½ inches in length by 1 foot wide, and 2½ inches in height in the flange, and are named according to their sizes *bipedales*, or two foot; or *sesquipedales*, or 1½ foot tiles; some are slightly convex, and sometimes more convex, and at the Byzantine period, some of the roofs seem to have been gilded. Besides for roofing they were used for the floors of the hypocausts, *suspensoria*, or low storied houses, *attegia*, *tegulicia*, and graves; flue tiles or pipes, *tubi*, scored at the sides with a hackle or comb, fixed with a small nail of lead, *clavis muscaria*, were used for heating winter apartments or conveying the smoke from the furnaces of the hypocausts; wall tiles, *bipedales*, with various ornaments; cylindrical drain tiles, *tubuli*, sometimes hemispherical and open, above 8 inches diameter. Fragments of bricks and tiles were used for the *ruderatio*, or understrata of roads, and for the red *tesseræ* of mosaic pavements. The brick and tile makers, *teguli ab imbricibus*, *tegularii*, stamped on the tiles inscriptions in bas-relief letters. Those on the Roman tiles often are circular medallions with a device, the name of the fabric, *opus doliare*, or "pot work," the consuls when made, the farms, potteries, *officinæ*, *figlinæ*, *doliares officinæ*. These inscriptions commence about A.D. 100, and end A.D. 222. When the tiles were made by the military, the *decurio* of the workmen stamped on them the name and titles of the legion, cohort, or other military division by whom they were made, in an abridged form. Other portions of architecture, especially friezes with mythical and other subjects in flat bas-relief, affixed by leaden plugs or nails to the impluvium, and painted in gay colours in *tempera*, were also made of a terra cotta like the bricks. Much care was bestowed on this branch of the fictile art, and the times specified for their fabric in spring and autumn, and Hostilius Saserna the elder and younger, two writers on agriculture, had, according to Varro, written on the subject of the potteries. Although the Romans imported under the republic statues from Etruria, at a later period they were made in the Roman territories; the principal statues of this material at Rome were a Felicitas, made by order of Lucullus, and a Venus Genetrix for Julius Cæsar; in later times terra cotta statues were gilded. Few figures of large size have been found at Pompeii, Pozzuoli, near the Porta Latina at Rome, and at other places.

Throughout, however, the Roman empire, small figures of terra cotta called *sigilla* or *sigillaria*, used for votive or religious purposes, for presents on the festival of Saturnalia, some representing deities, others personages of common life, or grotesque figures like modern toys, which were also called *crepundia*, were sometimes made of terra cotta, by particular potters, *sigillaria* or *signarii*. A pottery for the manufacture of these figures with moulds has been lately found at Moulins, and in the valley of Allier; others of the Gaulish goddess Nehallenia have been found at Autun, Dijon, and a few in England. They are generally of a white or pipe clay, and rarely have a potter's name. Terra cotta was also employed for miscellaneous uses, such as the crucibles and moulds of the false coiner, and great quantities of lamps, *lucernæ*, were made of this material. These were stamped out of moulds, *formæ*, by potters called *lucernarii*; the body is generally of a circular shape, with one or more projecting nozzles, and the handles in shape of lunes, busts of Serapis, antefixal ornaments or plain rings. They are generally only a few inches long, and slightly concave on the upper surface, on which are stamped, in bas-relief, deities, animals, fables, subjects taken from the poets, the games of the circus, and amusements of the streets. At a later period in the empire, the Jews or Christians used as a device the golden candlestick, the monogram of Christ, and other religious devices. These lamps have generally on their base letters stamped in, either the name of the potter, and potteries, or the place and date. The principal lamp-makers lived at the Porta Trigemina, situated at the foot of the Aventine, and towards the Tiber, where Cacus the robber giant had dwelt, close to the Salt Springs or Salt Pans, and on the Vatican. The trade was active, and the lamps appear to have been imported throughout the empire. Besides the normal type, some fancy shapes occur, such as a pair of feet and a gladiator's helmet. Lamps were in great use for household purposes, illuminations, funerals, and votive offerings. Notwithstanding the introduction of metallic vases in the latter days of the Republic, the Romans, especially the poorer classes, made various kinds of earthenware vases for all household and some religious purposes even during the Empire. Large casks, *dolia*, made of a coarse red, white, or yellow clay, and 7 or 8 feet high, hooped with lead, were made by particular makers called *doliarii*, and used as vats for holding wine; they were made in the same manner as the pithoi, and they gave the name of opus doliare to earthenware. The Roman potters used the wheel and moulds for the production of other vases, and kilns of potters have been discovered in Germany, France, and Britain with vases, remains of materials, and tools. The principal vases are the unglazed yellow used for amphoræ, lagænæ, bottles, a flat vase with a spout called the *mortarium*, and many small pateræ; cups and bowls, bottles, cadi, gutti, ollæ or jars, cups, calices, mortars, and sometimes amphoræ were often made of a pale red ware, the paste mixed with a small quartz pebble; a kind of gray ware made of a sandy loam, resembling stone ware, was used for mortaria and amphoræ; small plates, *patellæ*, cups, *pocula*, or *ciboria*, stands for vases, or candlesticks, *cerulæ*, were often made of unglazed black, ornamented with engine-turned, or thorny, or scaly ornaments; this ware is of late period, and probably succeeded the other ware about the 3rd century A.D.; a few vases of small size for the table have been found of a brown ware, and a class of small vases with egg-shaped bodies and tall necks—the ancient phials.

At the close of the Greek vase art, the paintings had entirely disappeared; the vases entirely coloured black, being ornamented with subjects on relief in imitation of relief ornaments, *crustæ* or *emblemata*, of metallic vases, and vases of this class appear to have been made in black and red glazed ware at Cuma, Capua, and Aretium. This ware, the finest produced by the Roman potteries, and apparently commencing about the 1st century B.C., was called Samian by Plautus, and the writers of the close of the Republic, but Campanian by Horace and writers of the Empire. Vases of this class have indeed been found in the Greek islands, and may have thence been imported originally to Rome, but the chief site of the fabric was in Aretium, whence it is frequently called Aretine ware. It is distinguished by its close compact paste of a bright red coralline colour, breaking with a fracture like sealing wax, and glazed externally with a mere polish or very thin siliceous glaze. The vases are of small size chiefly bowls, *trullæ*, cups, *calices*, bottles, *gutti*, flat, circular, or oval dishes, tureens, either plain and turned on the wheel, or else ornamented externally with subjects in bas-relief, and made from moulds. These moulds were made of a hard compact and pale red clay, and the subjects were produced from moveable types of hard clay set up into compositions and stamped on the moulds. The subjects are taken from Roman works of art and mythology, the principal buildings and statues of Rome, gladiators, amusements of the circus, and erotic scenes, or arabesque and floral ornaments. The subjects are arranged in one or more friezes round the vase, and fill up the external surface. These vases are impressed with the names of above 500 potters, some of Gaulish origin, showing that the red ware was manufactured in France and Germany. In the plain vases the names are stamped on the inside of the bottom, while on the vases with bas-reliefs on tesseræ with letters in relief; the names of the potters are preceded or followed by the expressions M (anu) by the hand, OF (ficina) the establishment, F (ecit) he made. The majority are slaves distinguished by their single names, but the single names of freedmen or free proprietors appear on some specimens. The potters were called *figuli* or *figulinarii*, as makers of vases *fictiliarii*, and *vascularii* and *ampullarii* or pot makers. The merchants who dealt in the ware were called *negotiatores artis cretariæ*: traces of their manufactories and shops have been found at Nancy, Paris, Nismes, Lyons, Clermont, near Bourdeaux, Rheinzabern, Heiligenberg, and Mayence; while the ware has been found as far east as the Crimea, and west, as the W. coast of England, and distributed throughout Italy, Greece, Asia Minor, the Islands of the Ægean and Archipelago, and the confines of the Roman empire. There is a great difference in the ware; that of the 1st century B.C. from the potteries of Campania being of finer earth and glaze, ornamented with relief sometimes delicately executed. In Northern Europe, that made under the first Cæsars is of the finest colour, brightest glaze, hardest paste, and best executed ornaments. Under Vespasian and his sons the paste is good, but no longer fine, and the vases resemble imitations of the earlier ware. At the time of the Antonines, A.D. 120, true Samian is no longer found, the shapes are still good, but the fracture and glaze are coarse, and coloured with red lead, or sulphate of iron, and an inferior glaze. After the age of the Antonines, the decadence is still greater, the colour and glaze of the false Samian much worse. From some of the figures the art appears to have been continued to the 4th century A.D. Some of the later vases are decorated with relief ornaments *à barbotine*, produced by squeezing the clay when moist out of a pipe or spoon, and modelling it into the required shape with a tool. Vases of this ware have also patterns cut with a sharp tool out of the body of the vase, in imitation of the diatretum or engraving on glass. The principal sites in Italy for celebrated vases under the Empire were Aretium, Allifæ in Samnium, celebrated for its cups, Pollentia, Surrentum, Modena and Rhegium, besides those already mentioned. A few vases of lustrous black ware were made by the Romans, but the red Samian or Roman ware seems to have been succeeded by a glazed black ware, probably as early as the 3rd century in Gaul and Britain, made by the native potters. These vases are of various pastes, made by the wheel, but often decorated with subjects *à barbotine*, consisting of gladiators or hunting scenes and ornaments punctured in or incised. The principal sites of the fabric were at Castor and the Upchurch marshes near Sheerness, and at Crockhill in the New Forest; the paste of this last is made of a dark gray clay, and the surface covered with an alkaline maroon glaze; the Castor ware was made of a gray clay, and the external colour is supposed to have been produced by condensing the smoke of the kiln on the vases while baking; the Upchurch ware is made of the London clay with an external black glaze or polish, that found at Crockhill was made of a local blue clay covered with an alkaline maroon glaze. Small vases, principally drinking cups, with corrugated sides, were made of this ware. Similar wares, but occasionally impressed with the names of potters in relief, have been found in France and Germany; and a black glazed ware with a red paste, having in slip of pipe clay such expressions as AVE hail, BIBE drink, DA VINVM give wine, in the shape of jugs and bottles, and perhaps as late as the 4th and 5th centuries A.D. Besides these imperfectly glazed vases of a tender lustrous pottery, the fabric of an enamelled or glazed terra cotta, covered with a thick siliceous glaze, in some instances produced by hand, seems to have been handed down in Egypt, and the products in the shape of lamps and jugs imported from Alexandria throughout the Roman world, a fact important to be remembered in the history of the revival of glazed ware in modern Europe.

The aboriginal natives of northern Europe, the Celtic, and Teutonic, and Scandinavian races, had from the earliest period a rude pottery, consisting of coarse vessels of clay, of rude construction, with open mouths, thick walls, made of a paste of clay mingled with small pebbles, and imperfectly baked in rude furnaces by means of wood, straw, or weeds. This ware, more or less brown or gray, is found in the lowest stratas of human remains, the tumuli of the races which used stone and bronze weapons, and in the oldest cromlechs. It was not made on the wheel, but fashioned by the hand; and the ornaments imitate the rude tattooing of the natives, and the decorations of their jewels, consisting of hatched bands, chevrons, zones, and other designs, either impressed by twigs or rushes. These vases, known to the Romans as *bascaudæ*, or baskets, and imported to Rome, hold the ashes of the dead; some few are of small size, and all appear to have been employed for household purposes. They exhibit great local differences, and some of the most remarkable are those in shape of ancient houses found at Chemnitz in Thüringen, at Roenne, in the isle of Bernholm, and at Parchim. These native wares appear to have never been entirely superseded by the Roman wares amongst the Northern races; and the Germans and Anglo-Saxons, Scandinavians and Gauls, under the first dynasty, manufactured a kind of ware of a dark paste, imperfectly baked, or even sun-dried, and in the shape of jars, ornamented with impressions from bone or wooden stamps, representing fleurettes, crosses, triangles, and other ornaments, disposed in bands or rows round the neck of the vases. The use of glass, horns, wooden cups, and jugs of perishable materials, caused, however, the disuse of smaller vessels of earthenware. After the fall of the Roman empire, the working of terra cotta disappeared with the decline of the arts, and only reappeared with their revival. Large and remarkable pieces, as that of S. Antony, were executed, however, by Nicolo of Arezzo, in the 14th century, for his native town; and in the 15th, Simon made a Magdalen of heroic size for Florence. Celebrated works of Mazzoni Guido Paganino of Modena, and Belsa of Florence, are still seen in that town, Venice, Ferrara, and Naples; and in Spain, in the 16th century, Miguel made colossal statues of St. Paul and St. Peter, for the cathedral of Seville; and Germain Pillon, in France, at the close of the same century, executed colossal religious works. During the 18th century, however, only coarse figures for gardens seem to have been made of this material. At the close, however, of the last century, the art had considerably revived, both for sculpture and architecture; and in France, both Clodion and Mène executed works of merit in this material. The application of terra cotta to buildings and sepulchres has had, however, a greater extension, and the buildings of Toulouse, Dresden, Berlin, and Munich, the churches and other edifices, are often enriched with terra cotta reliefs and other ornaments. The use of bricks, which it is scarcely possible to conceive can have been entirely lost, is said to have been re-introduced into England by Alfred in the 9th century, but according to the best authorities does not date earlier than the 14th century.

The manufacture of a soft fine pottery, and of a coarse pottery unglazed by plumbiferous or stanniferous glazes, seems to have prevailed all over the habitable globe. Great jars, imitated from the ancient dolia, are still made in the Puy de Dome, in France; near Florence; in Spain, where they are called *tinajas*, in Armenia, named *kapchines*; by the Bushmen of Africa; the Javanese; the Guaytokares, or old Indian tribe of the Corrados, on the banks of the Parahla, in Brazil, where they were employed to hold the bodies of the dead. Smaller vessels of unglazed earthenware, for common purposes, are now made all over Europe. One of the most extensive classes are the water coolers, a kind of bottle of porous clay, called *alcarazza* in Spanish, *alcaradza* in Portuguese. Spain is particularly celebrated for their manufacture, which is said to have flourished as early as A.D. 894, and they are still made in Valencia and Andalusia. The principal Asiatic pottery of this class is stated to be the fine red ware of Anatolia, that of Broussa, the yellowish white of Mecca, the red coffee-pots of Has in Yemen, the red clay pipe bowls of Sana, the water bottles of white ware of Cora in Persia. In India the character of the ware resembles in its type that of China; Chandranagore, Pondicherry, and Kanial manufacture red and brownish lamps for pagodas; at Calcutta the ware is reddish brown and micaceous. The pottery of Cochin China is fine, hard, light, and turned; of Manilla, white and turned, with another fabric introduced by the Spaniards. Ceylon produces spheroidal vases, of a red paste; Java, red turned pottery; Sumatra, at Palembang, water coolers of a pale reddish-brown ware. Manfaloot, in Egypt, makes great jars of yellow clay for holding indigo, and *selah mograbby*, or white water coolers of Marocco, the *zyr* or common jars, and at Khenneh in Upper Egypt *bardachs* or water coolers, of a thin yellowish ware, are made in such abundance and so cheap as to be seldom used twice. Algiers and Tunis produce a whitish pottery, thin and turned; and that of the Nigritic tribes, in the centre of Africa, chiefly from Kana, is either of a pale reddish-brown with coatings of red or white colour, or else of a black colour, feebly baked. At Madagascar the pottery is of an ashen gray and micaceous paste, sometimes with black anthracite bands.

The aboriginal pottery of America resembles in its general characters, the rudeness of its type, ornamentation, and baking, that found in other parts of the world. That found in the northern states, in the tumuli at St. Louis, near the river Merrimac, in Ohio, in Louisiana, Virginia, and Tennessee, has its paste often mixed with the shells of the Myas anodonta, and is ornamented with lines and hatched marks. These potteries are of the rudest kind; those of the Toltec and Aztec nations, which are found in Mexico, show greater artistic merit, and are principally of red ware, ornamented with native patterns in white pipe-clay, sometimes modelled in various shapes, and decorated with modelled ornaments of figures of deities and other objects, occasionally covered with a siliceous glaze. In terra-cotta figures of deities the natives particularly excelled, and have retained the art, modified by Spanish influences, to the present day. In Mitla, Palenque, and Copan, many objects of various kinds, in terra cotta and soft pottery, have been discovered. The pottery of Mexico at the present day is described as peculiar, of a dirty white, pearl gray, reddish yellow, or black colour, light, and sometimes reddened with ochre, never made by the wheel, but decorated with ornaments of a black colour, and similar to that of the Antilles and Martinique. The ancient potteries of South America resemble in their general characteristics those of Mexico; in the *huacas*, or tombs of the ancient inhabitants of Peru, especially those near the Lake Titicaca, vases, principally water bottles, of a fine red clay like the Greek, or a dark clay like the Etruscan ware, are found in numbers; they are light, always made by the hand, never by moulds or the wheel, but often are modelled with considerable skill and taste in shape of human heads, men, and animals, and decorated with ornaments resembling the Greek meanders, or with animals on the body, and handles. Some resemble the Chinese, especially certain vases with a gourd-shaped body and bifurcated necks; and many with double mouths, when blown into by the mouth, give forth a whistling sound. The potter's art was exercised by all tribes of the continent except the natives of the Pampas. In Brazil the ware is of a red or black colour, modelled in shape of fruit or animals, and coated with an unctuous varnish. The modern ware of Peru differs from the ancient, but still retains a local character. At Lima and Callao a red pottery, covered with an ochreous coating, and a blackish ware, all hand-made and feebly baked, is manufactured, along with a coarse red pottery at Itaty. North of Corrientes coarse black *tinajas*, in imitation of the Spanish, are made. The ware of Chili resembles that of Peru; that of Paraguay is black.

The Moors are supposed, on the conquest of Spain, A.D. 711, to have introduced into Europe the use of glazed tiles from Asia, similar tiles having been found in the mosque at Medina, A.D. 707, and in the early churches of Pisa, Pavia, and Sicily; but none of these tiles *azulejos*, found in the Alhambra, appear to be earlier than A.D. 1300, and are made of a pale clay covered with a white enamel, on which a pattern has been stamped or painted in blue and brown, and covered with a stanniferous glaze. Three classes of plates and other vessels of a fayence enamelled with white or yellow ground, on which are shields of the kings of Spain, cyphers, arabesques, and ornaments, are supposed to have been made by Moorish potters from the 13th to the 15th century. They are distinguished by the cupreous iridiscence of the glaze. But enamelled vessels, of a date even earlier, have been found in England, either the works of English or foreign potters. The principal sites of Spanish pottery were Talavera, Valencia, and Traña in Andalucia.

The custom of bringing home enamelled plates, *bacini*, by the Crusaders, and the conquest of Majorca by the Pisans in A.D. 1115, introduced the tin glazes into Italy, which are supposed to have been first used by Lucca della Robbia, A.D. 1415–1420, who made scriptural subjects in high relief; and tiles of glazed ware, principally white, although other colours, as yellow, blue, green, and violet, were also used by him and his family till A.D. 1560. The name of *Majolica*, from the island whence it had first come, and of *Raffaelle*, from the great artist who supplied some of the designs, has been given to this ware. The early kind from A.D. 1540 to 1560, called *mezza majolica*, ornamented with arabesques, coats of arms, busts, and portraits, is distinguished for the brilliancy of its colour and the iridescence of its madreperla glaze, the ruby tint being peculiar to the products of Pesaro and Gubbio, and supposed to have been invented by Maestro Giorgio. The *porcellana* or finer ware subsequently introduced is remarkable for the excellence of its paintings made from the designs by Raffaelle, Marc Antonio, and others, of scriptural and classical subjects, in light but harmonious colours. The ware declined from 1560, and in 1574 the ducal establishment of Urbino was suppressed, the art having been up to that period fostered by the dukes of Urbino. This ware was introduced into Faenza, Forli, and Rimini. The principal shapes are the *piatti di pompa* or plates, but flasks and bottles for the ducal spezieria, and pilgrims' bottles were also made. The subjects are often accompanied by explanatory inscriptions, the objects, date of vase, and initial of the potter, being generally placed on the back. The principal artists were Maestro Cencio and Orazio Fontana. The ware continued to be produced in Italy at Naples, Castelli in the 16-17th century, and at Siena, Savona, and Urbania, till the 18th century.

The manufacture of Majolica was introduced into France by Catherine de Medici, A.D. 1590, and flourished at Avignon, Nevers, St. Cloud, and Rouen till the close of the 17th century; but the ware peculiar to France was that of Palissy, invented by the celebrated potter of that name at Saintes, A.D. 1555, who from beholding an enamelled cup of Majolica or Nuremberg, after many years of laborious and unsuccessful experiments, made vases of a gray paste covered with a hard enamel and painted with bright and varied colours, chiefly cold in tone, and ornamented with fish, reptiles, flowers, and other objects, moulded from nature, found in the vicinity of Paris. His principal works were dishes, pièces rustiques, thus ornamented for sideboards, stands or basins, tiles, dishes, and jugs ornamented with religious and other subjects in relief. The art was continued by his family, but with less taste and excellence. Besides the Palissy ware a peculiar fayence called that of Henry II., consisting of a glazed hard paste of pipe clay covered with a transparent glaze, appears to have been made about that period in France. It is peculiar for stencilled patterns of mixed colours, with a predominance of yellow ochre, often with moulded figures, while encaustic tiles similar to those made in England were manufactured in France in the 13th century, and a glazed ware is supposed to have been made at Beauvais in the 14th century.

In A.D. 1278 a glazed ware is said to have been made in Alsace; and in the 15th century Ratisbon, Landshutt, and Nuremberg produced vessels with a green glaze. In A.D. 1503 Majolica ware was introduced into Nuremberg, and flourished chiefly in Franconia till the 16th century. Tiles of this ware were made till the middle of the 17th century; the same kind of ware of coarse and bad paste was made at Strasbourg and Frankenthal, and a very fine ware of this kind was produced at Hochst, but the style was abandoned in the middle of the 18th century for porcelain. At Cologne and Mansfield a fine clear paste with thin enamel, and at Wagram, and in Hungary, majolica, was manufactured. A fine enamelled ware is still said to be made at Popplesheim. The German ware is very different from the French and Italian in style and colour and shape, which are quaint and peculiar, chiefly of floral designs: animals were often moulded for drinking cups. In A.D. 1310, Delft in Holland is said to have manufactured pottery, and during the 14th and 15th centuries produced vessels and enamelled tiles. After the separation of Holland from Spain towards the close of the 16th century, A.D. 1579, the potters copied with great success the shapes, drawings, and glaze of Japanese porcelain, and produced an imitation of oriental, which from its thinness, lightness, and cheapness commanded the European market till the beginning of the 18th century, but rapidly declined in the 19th, having been superseded by the English. Chinese porcelain was also imported into Holland and England. Like the French and Italian wares the Delft has the initials or monogram of the potters placed on it. In Holland and Flanders also were manufactured in the 16th century jugs of stone ware with a bearded head in relief on the neck and coats of arms on the belly, nicknamed gray-beards or Bellarmines, in derision of the Cardinal, and of a gray or mottled brown colour; and were made in Holland and at Cologne, and a fine kind of tankard called Jacobus Kannetje, of an unglazed yellowish paste, stamped with reliefs from copper moulds, were fabricated on the lower Rhine and in Holland by the celebrated Jacqueline, Countess of Hainault, A.D. 1433. This stone ware was glazed by salt, and some of the blue vases are the finest products of the German potteries, which flourished till the beginning of the 17th century, and are known as the Flemish stone ware.

The earlier Anglo-Roman and Saxon vases of England appear to have ceased prior to the Norman invasion, the Saxons having extensively used horns, leather bottles, glass vases, and other materials; but the manufacture perhaps revived under the Plantagenets. The earlier English pottery consists of encaustic tiles of red brick, with relief, sunk or inlaid or laid on patterns, used only for religious edifices, in the latter part or the 12th or beginning of the 13th century; the oldest ornamented with heraldic bearings or badges, those of 13th-15th, with elegant foliage, and arranged in sets of single tiles of 4, 9, or 16 to the set, with heraldic bearings, mounted knights, grotesques, and inscriptions, till they were superseded in the 16th century by Flanders or gally tiles of foreign manufacture. Tiles of all these classes have been found in the principal old religious edifices of England, and appear to have been made in potteries attached to the monasteries, kilns having been discovered at Bawsey near Lynn, Droitwich, Malvern, and Saredon, some built of semicircular arches separated from each other by a massive pier.

In manuscripts of the Norman period earthen vessels are represented, and the *cruskyn* or *cruske* is mentioned as early as A.D. 1324, and in works of the 14th century, the *godet* or *godette* about the same period, the *costrel* or flask, hung by a strap to the side, and *tygs* or cups. The accounts of the executors of Eleanor, wife of Edward I., mention a payment for pitchers to Juliana the potter; but her name appears to be foreign, and it is uncertain whether they were not Flemish; in A.D. 1446, the accounts of Sir T. Howard contain orders for payment to the potters of Horpesley for earthenware jugs, and so do those of Edward IV., and in 1512 they were in use in the household of the Earl of Northumberland, and continue to be mentioned till the close of the 16th century.

The existence of early English potteries has been proved by the discoveries of moulds as old as Edward III., and of jugs, pitchers, costrils, and other vessels at a depth, and under circumstances showing that some must have existed as early as the 11th century. They are made of a coarse brittle brown paste, covered with a black or green plumbiferous, or leaden glaze; some of the most remarkable are wine or water pitchers, moulded in the form of Norman knights of the time of Henry II., or with heads of that of Edward II. This ware was continued till the commencement of the 18th century, and often has dates in the 17th century; a late pottery of it was at Wrotham. As early as the beginning of the 17th century Dutch potters are said to have established potteries of Delft ware at Fulham and Lambeth, and wine pots dated 1642 and the following years, and other vessels of this ware, are known till the close of the 17th century. Delft was made at Liverpool about the same period, and at Lambeth till a late period, but during these centuries, stone pots or Bellarmines, from Flanders, were extensively imported, although this ware appears to have been made in England at the time, while porcelain, mentioned as early in France as 1370, in the reign of Charles le Bel, began to be imported into England in the reign of Henry VIII. and Elizabeth, in 1587, and was later called China, and came from Venice; a heavy duty was laid upon it by Cromwell. But the chief seat of the English potteries was in Staffordshire, at Burslem, where coarse culinary vessels of red, brown, and mottled pottery were made. It is here that in 1670 were made the butter-pots of cylindrical shape, and of sufficient capacity to hold 14 lbs. of butter, the size and quality of which was regulated by an act of parliament. The vicinity supplied various clays suited for the different wares, and a lead glaze was obtained by the use of galena, or sulphate of lead. In 1680, salt glazing was accidentally discovered. In 1685, white and brown stone ware was made from local clays, and Crouch ware in 1690, glazed by salt and red lead. In the same year the Elers, brothers, of Nuremberg, established themselves at Bradwell, and attempted to produce an imitation of the red Japanese ware; but their secret having been discovered by Astbury, they removed to Lambeth or Chelsea in 1710. Astbury, who at first produced red ware, afterwards made a white dipped, or white stone ware of Bideford pipeclay and Shelton marl, and in 1720, the use of flint was discovered, and slip kilns for boiling the clays; and plaster of Paris moulds were subsequently introduced. Improvements in the working of the clay were made by Booth about 1750, but the great stride in the potteries was made by Wedgwood, who produced an improved *cream* ware in 1759, which was named *Queens* ware, after Queen Charlotte. From 1760-62, he invented six different kinds of ware; he was the first to introduce a classical style and fine modelling, by the aid of Flaxman, into the art, and showed as much taste in the moulding of his pieces as excellence in the ware, which, made of the fine grey marl from under the coal strata, produced a material uninjured by the vicissitudes of temperature, of a cane colour, and at first ornamented by a rude border, was subsequently covered with a pattern; he also made terra cottas, basalt, jasper, granite, and onyx wares, especially plaques, medallions, and works of taste and vertu of a blue jasper ware, with white figures in relief, which obtained a great European reputation. As early as 1767 the discovery was made of applying printed designs from copper-plates to pottery, which was thus decorated at Liverpool by Carver and returned to Burslem. Sarah Elkin, a servant of Wedgwood, first discovered a successful method of gilding earthenware, and J. Hancock, about 1800, used a process resembling water-gilding for the same purpose.

Although Cornish clay was introduced into the Staffordshire potteries, the manufacture of hard porcelain is said to have been restricted to Plymouth and Bristol, and only flourished there for a short period. Towards the close of the last century, felspar was first introduced into the Staffordshire ware by Spode. Bones or phosphate of lime were first used about 1800, and made an important change in the manufacture of soft porcelain.

At Lambeth, the site of early pottery, delftware continued to be made till recently, and stoneware is still made at Lambeth and Vauxhall; potteries also existed at Fulham, Bristol, and Leeds, in the 18th century, and at Liverpool from 1674 chiefly of delftware, where, in 1753, Sadler and Green first employed printing upon pottery; and Chaffers here established a manufactory of white earthenware; and another potter, Pennington, in 1760, produced a very successful blue colour, and imitations of oriental vases. The principal pottery here in later times was the Herculaneum, established in 1794, and continued until 1841, which produced China of a peculiar character, and stamped with the name of the manufactory. At Lowestoff a pottery was commenced in 1757, but abandoned forty years afterwards; and another existed at Nottingham in 1641; and at Saçkfield a pottery was established for stoneware in 1713, but ceased about 1800; and an obscure pottery was set up by one Place, at York.

Similar to pottery, but technically distinguished from it by its unchangeability under extreme temperatures, its translucency, and its superior hardness, is the material called *Porcelain.* The term is of uncertain derivation. The material, invented by the Chinese, consists of kaolin or alumina, and pih-tun-tze or silex, which according to the proportion in which they are mixed form a hard or soft porcelain. It was invented at Sinping in China, in the time of the Han dynasty, between B.C. 185-88, made considerable progress in the 3rd century, A.D. under the Wei, and a blue kind was made at Tunggaon in the province of Chekeang, under the Tsin, who commenced A.D. 265, and continued till A.D. 419; subsequently under the Chin, A.D. 583, the celebrated potteries of Kingtechin made porcelain for the imperial court. The colour varied according to the dynasties, blue, green, and white in turns prevailing. Porcelain was also manufactured in A.D. 954 in Honan, in A.D. 960-1279 in Soochow, and in the city of Tingchow in Pihchele. Crackle porcelain was first made at Soochow, and the other localities produced different colours and patterns; but the principal site was Kingtechin, which, commencing in A.D. 581, has continued till the present day. In A.D. 1506, foreign cobalt was introduced, and about 1573, the delicate eggshell-ware was invented.

Marks are found upon Chinese pottery, sometimes animals or objects, at others inscriptions, principally imitations of seals stamped upon books in vermilion or blue with seal characters. The oldest date known is that of Hungwoo, A.D. 1368, and the practice has continued till the present time. The principal varieties of Chinese porcelain known to Europe are the pure white, the blue and white, or Nankin, the Soumali blue, the Celadon green, the marbled or shot, the citron or imperial ware, the ruby blue or brown. Besides porcelain, the Chinese extensively manufacture and use a terra-cotta, and unglazed and enamelled earthenware. The manufacture of porcelain was introduced into Japan, B.C. 27, and the potteries are situated at Imari in Fizen, and at Firose. The porcelain is whiter, of better quality and style than the Chinese: but in other oriental countries it appears doubtful whether hard porcelain was known. As early as the 8th century, the Chinese carried their wares to the coast of Arabia, and in A.D. 1154, porcelain is mentioned by Edrisi. In the 13th century, Marco Polo describes the manufacture, and in the subsequent centuries it was exported to Barbary and Florence, but the first regular importation was by the Portuguese in 1518, and an extensive trade was carried on by the Venetians, Dutch, and English. Its first appearance in this country was A.D. 1504. The passion for collecting China appeared in Europe at an early period of the 16th and 18th centuries: Charles V. in 1541, presenting a set to Maurice of Saxony; Louis XIV. ordering services of porcelain from China; Mary the wife of William III. of England collecting China; and Frederick Augustus of Saxony in 1717 founding the collection of the Grüne Gewölbe at Dresden. In England the passion still continues, immense prices being given for fine specimens of ancient Chinese porcelain. Two hundred years after the importation of porcelain, Böttcher of Berlin, in 1715, produced a perfect white porcelain at Meissen, near Dresden, in the reign of Augustus II.; his first attempts produced a red stoneware like jasper, or with a glazing of brilliant colours, and Chinese patterns; but under subsequent management, Höroldt in 1720, and Kandler, a sculptor, in 1731-56, improved the paintings and shapes; grotesque modelled figures and ornaments in the floral and rococo style were extensively manufactured. The art, although guarded with jealous care, was soon carried over Germany; Stöbzel, a foreman of the Meissen establishment, fled with his secret to Vienna in 1720, and established a fabric which differs in glaze and thickness from Dresden. Other manufactures were set up in Bohemia, and in Hungary; Ringler, a workman of the Vienna factory, carried the secret in 1740 to Höchst, near Mayence; and the establishment rose to repute under Melchior, a modeller. Busch, a Saxon, established it at Keltersbach; in 1750 Bengraf, a Höchst workman, worked for the Duke of Brunswick at Fürstenburg; Ringler also set up a manufactory in 1755, at Frankenthal, which continued until 1800; and lesser establishments arose at Nymphenburg, and Baden, and Ludwigsburg. At Berlin a private establishment, set up in 1751, was subsequently purchased by Frederick the Great, and attained an excellence and eminence which it still retains. Other porcelain manufactories also flourished in Hesse and Thuringia; and were also introduced into Russia by the Empress Elizabeth, in 1751, at Twer and Korsec. In Holland, at Amsterdam and the Hague, and at Arnheim, unsuccessful attempts to manufacture porcelain profitably were made; and at Copenhagen, at Zurich, and at Nyon on the Lake of Geneva, with better success.

The introduction of porcelain into England created the soft porcelain. The history of the earliest manufacture is involved in much obscurity. A manufactory established at Stratford-le-Bow was abandoned in the early part of the 18th century, having been probably established in an early part of the 17th century. The specimens were painted and modelled by Frye, Moser, Bacon, &c. At Chelsea, the porcelain or *gomroon* ware, as it was then called, was made earlier than 1695. At first it imitated, in its blue and white patterns, the Chinese or French models; but George II., the Duke of Cumberland, and others, procured superior means of manufacture from Germany, and under the management of Spremont it attained great excellence; but the potteries were abandoned in 1765. The vases were modelled by foreign artists in forms resembling Dresden, and painted by first-rate painters, while a fine claret colour is said to be peculiar to this fabric. Many of the drawings are very beautiful, and the vases realise immense prices. On the abandonment of the Chelsea works a factory was subsequently set up at Derby, where the moulds, workmen, &c., had been transferred, but has since been discontinued. Those of Worcester, founded by Dr. Wall in 1751, who is said to have invented the art of printing upon porcelain, not only attained, but maintain great excellence. At first they imitated the Chinese, then the Sèvres and Dresden ware and fancy ornaments. Rockingham, established in 1757, is best known for its brown or chocolate ware. At Colebrooke Dale in 1756, at Nantgarrow in 1813, and at Leek in Staffordshire, minor establishments of porcelain have flourished. The manufacture of hard porcelain in England, commenced by Cooksworthy at Plymouth in 1705, and subsequently transferred to Bristol in 1776, was abandoned since that period, till revived by the late Mr. Minton in 1850.

The soft porcelain of France was manufactured at St. Cloud as early as 1695, and was succeeded by that of Vincennes in 1740, which attained great perfection and modelled bouquets of great beauty about 1754; but two years afterwards it was removed to Sèvres, under the patronage of Madame de Pompadour. In 1768 the accidental discovery of kaolin and pihtunse led Macquer, the superintendent of the establishment, to the production of hard porcelain; but the manufacture of soft porcelain was not entirely abandoned till 1804. This manufactory has produced the most beautiful examples of European porcelain, distinguished by the beauty and brilliancy of its colours, the dark and light blue, yellow, green, and Dubarry, or rose-pink, and the elegance of its paintings, after Watteau and other artists, although the forms till 1785, when classical shapes were introduced, by no means equalled its rivals of Dresden. The high prices and demand for this elegant article of vertu have led to various counterfeits, the doctoring of old specimens, and the fabrication of modern imitations, so that it is as difficult to detect spurious Sèvres porcelain as false coin. Other places, as Chantilly in 1735, Orleans in 1753, Arras in 1782, Tournay in 1750, and Paris in 1773, manufactured soft or hard porcelain; and in 1735, at La Doccia, near Florence, a hard and a hybrid porcelain was manufactured in imitation of oriental, Sèvres, and Capo di Monte, distinguished by its modelled forms. At Venice the manufacture ceased in 1812. At La Nove, near Bassano, in Lombardy, at Turin in the end of the 18th century, and at Capo di Monte, near Naples, a porcelain, finely painted and moulded in high relief with shells and figures, is said to have flourished from 1736 to 1821, an offshoot of which was established at El Buen Retiro, near Madrid, about 1759, but was completely destroyed in 1812; but another fabric was subsequently established near Madrid in 1827. A fabric of hard porcelain flourishes at Vista Alegre, near Oporto.

Although the use of vessels with plumbiferous glazes has been in great part superseded by other wares, yet it is still extensively manufactured in England, France, Germany, Portugal, and in Switzerland, different localities using different processes, as the actual metallic lead in Finisterre, and the galena in other places, as in Sardinia. The manufacture of majolica has in fact never quite disappeared in Europe; into Naples it was introduced at the close of the 18th century, and pieces of a peculiar kind were made; the recent majolica of Venice is thin, with bluish-white enamel and ornaments in *repoussé* work. In Holland, a manufactory, the survivor of the delftware, still remains. Glazed wares of a green colour are made at Smyrna; in India, and at Pegu. The use of stanniferous glazes in the East has been continued till the present day, since an early period: they are still used in Turkey, Asia Minor, and Marocco, with red ornaments on a white ground, and oriental patterns. At Shershel, in Algeria, lamps are made. In Persia, as early as 1146, fayences of deep blue, with white ornaments, and of a golden colour at a later period, have been made. In Arabia, the use of enamelled wares, especially for tiles and other architectural ornaments, dates from the 10th or 11th centuries.

The modern potters, like the ancients, often placed on their ware inscriptions giving the name of the place of manufacture or of the maker. Those on the early French and Italian majolica are initial letters, monograms, dates, and coats of arms. Thus, Savona has the arms of the town; Nevers, N.; Rouen, a fleur-de-lis; B. stands for Bernard Palissy; Höchst has a wheel; Cologne, an anchor; Delft, occasionally a sword; Wedgwood and his successors stamped their names; old Dresden has the monogram A. R., King Augustus, K. P. M., "the Royal Porcelain Manufactory," and crossed swords; Venice, the imperial arms; Fürstenburg, an F.; Frankenthal, the lion and crown; Nymphenburg, the arms of Bavaria; Ludwigsburg, a ducal crown and C. C.; Berlin, a globe and cross; Fulda, F. crowned; St. Petersburg, a K. crowned; the Hague, a stork; Copenhagen, waves; Nyon, trouts; Chelsea, anchors; Derby, a crowned D; Plymouth, the astrological sign for Jupiter; Worcester, W. and other marks; Swansea, a trident. Sèvres has several marks,—a sun under Louis XIV., a crowned eagle under Napoleon, a comet; the other French potteries have monograms and marks. The Chinese marks have the name of the maker, or date when made, generally in red or blue, in a square label in the seal or court characters, imitating the impression of the seals or stamps they affix to their documents and books.

The application of the fine arts to the embellishment of porcelain, and the refinements of luxury, have vastly increased the value of modern porcelain. For a long time hard porcelain was the monopoly of princes, and the expense of producing specimens with charming colours and elegant designs was very great; but the desire of possessing beautiful and rare specimens by the rich has greatly increased their value: for example, the majolica salt-cellars have realised at public sales from 10 guineas to 64*l.*; the Gubbio plates from 11*l.* to 21*l.*; those of the artist Xanto 80*l.*, and vases of larger size 220*l.*; a Palissy candlestick, 84*l.* The ware of La Doccia has augmented its price 2000 per cent., and a small cup of this ware is worth from 30*l.* to 40*l.* Chelsea vases of any size, painted with religious or historical subjects, obtain from 100*l.* to 150*l.*, and small cups of this ware 25*l.* to 30*l.* Nor has the reputation of Chinese crackle declined, and even mandarins might pause at the prices given; 60*l.* and 70*l.* being paid for sea-green or turquoise blue vases. Green crackle has found amateurs to purchase at 131*l.*; and a few flat jars, surmounted by kelins, or mystical stags, 235 guineas. Last, though not least, two jars have been the subject of a suit in Chancery. Under such circumstances, the acquisition of instructive collections transcends the power of princes or the prudence of governments.

(Brongniart, *Traité des Arts Céramiques*, 8vo, Paris, 1844; Birch, *History of Ancient Pottery*, 8vo, Lond., 1858; Marryat, *History of Pottery and Porcelain*, [illegible]vo, Lond., 1857.)

POTTERY AND PORCELAIN, MANUFACTURE OF. The object of the present article is to add a few further observations to the manufacturing details given under EARTHENWARE; and to apply those details to the two kinds of ware which form the extremes of the series, namely, fine or *porcelain*, and coarse or *pottery: earthenware* occupying a medium position between the two.

In the beginning of the last century, it was ascertained by experiment that the earths alone are infusible, but that when silex is combined with aluminous earth, and subjected to a strong fire, it unites chemically with the clay, as an acid unites with a base; and that when a third earth, having alkaline properties, as lime, magnesia, or barytes, is added, a more complete change is effected, and a vitrified body is produced, resembling in density and fracture many natural gems. When the earthy materials are free from metallic matter, a perfect *porcelain* is thus produced. It was found that seven parts of silex, six parts of aluminous earth, and two parts of an alkaline earth, would produce such a body. On this principle the Germans and French founded their porcelain manufactures. In England the enterprising spirit of Wedgwood wrought a complete revolution in the art; and by bold experiments, guided by his knowledge of mineralogy and chemistry, he laid the sure foundation for all those improvements which have raised the fictile manufactures of this country to so high a level.

The materials are reduced to the consistence of cream, in which state they are called *slips* (slops); this fluidity is necessary to ensure the perfect mixture of all the ingredients, and their mutual chemical action in the fire. The basis of the composition is a clay from the plastic-clay formation in Devonshire or Dorsetshire, to which is added ground flint, which gives whiteness and solidity to the goods. For the better kinds, a portion of China-clay, or decomposed felspar from Cornwall, is added, together with a small quantity of ground white granite. The processes are conducted as described in EARTHENWARE, until a smooth and homogeneous mass of plastic clay is produced.

It may be well here to give the proportions of ingredients for various kinds of ware or bodies, derived from the actual practice in Staffordshire:—

Cream-colour or *Printed Ware.*—

Dorset clay	56 or	60 or	66
China clay	27	18	17
Flint	14	20	17
Cornish granite	3	2	

Drab-coloured Ware is made of the fine gray marl found between the coal strata, which burns to a cane-colour in the oven; or a white body, as above, is stained with oxide of nickel, which gives it a greenish drab tint; or with oxide of manganese.

Drab body.—

Cane marl	32 or	— or	56 or	26
Dorset clay	22	43	20	46
Cornish granite	45	50	24	25
Oxide of nickel	1	7	—	—
Manganese	—	—	—	3

The granite in the above bodies gives great density and a very close flinty fracture.

Brown or Chocolate bodies are made with a basis of the red ochreous clay, obtained from the red-marl formation above the coal strata. A great variety of tints may be obtained by judicious combinations of oxides of iron, as umber, calcined copperas, bole, &c.

Brown.—

Red clay	83 or	60
Dorset clay	13	30
Flint	2	10
Manganese	2	

Egyptian Black, for tea-pots, ink-stands, &c., is made in the same way, but with a larger portion of the oxides of iron and manganese.

Black.—

Red clay	45 or	34
Dorset clay	36	42
Manganese	13	12
Protoxide of iron	6	12

Blue bodies are produced by the mixture of a small quantity of oxide of cobalt with a fine white body; when made of vitrescent materials, so as to give a gem-like surface without glazing, it is termed *jasper*. This beautiful article is well known by the splendid productions of Mr. Wedgwood.

Jasper bodies.—

Sulphate of barytes	48	or	Carbonate of barytes	34
China clay	16		China clay	15
Dorset clay	24		Dorset clay	15
Flint	10		Cornish granite	33
Gypsum	2		White lead	3

These mixtures give a fine white body for ornaments, which may be stained blue by the addition of one per cent. or less of oxide of cobalt, according to the strength of tint required; or a green jasper may be produced by staining with protoxide of chrome.

Turquoise bodies.—A body called turquoise has been manufactured to a great extent. It is nothing more than a good white body, stained with a mixture of oxide of cobalt, combined with a large proportion of oxide of zinc; when glazed, it has the peculiar milky tint of the gem after which it has been named.

In this manner, by a proper combination of metallic oxides, either as existing in earthy materials, or prepared from their metals, an infinite variety of coloured bodies may be produced. They are usually prepared on slip-kilns of small dimensions, the bottoms of which are covered with a layer of plaster of paris, if used for the finer colours.

Referring to EARTHENWARE for an account of the manner of fashioning circular vessels on the potter's or *throwing* wheel; turning them to the proper thickness, and working mouldings, &c.; fixing on handles and spouts; and making the peculiar variety called *dipped ware:* we shall add a little to the details there given concerning *ornamented* ware and *flat* ware.

Thrown and turned goods are sometimes ornamented with figures in relief, which are made out of flat moulds by children, and fixed upon the ware by workmen, who, having carefully adjusted each figure to its place, run a little water under it with a camel-hair pencil, which unites it to the surface. Goods of an oval or angular shape, which cannot be turned, are made by pressing clay into plaster moulds, which give the outside form to the vessels. For this purpose the mould is made in two parts, and each is separately filled by laying in a cake of clay that has been beaten out to the proper thickness on a wet plaster-block; it is pressed into the mould by repeated blows from a ball of wet sponge, then squeezed into all the angular parts with the fingers, and smoothed with sponge, wet leather, and horn. When both sides of the moulds are thus lined with clay, they are joined together; and the workman lays a roll of clay along the inside of the joining, which he works down until the whole is smooth and solid. The mould is then carried into a stove-room; and when it has absorbed the moisture, so as to release the clay, the work is carefully taken out, and the empty mould returned to the stove previous to being filled again. The seam which remains on the outside of the vessel is removed by scraping and burnishing with wet horn; the handles and other appendages are then attached. This branch of the trade is called *hollow-ware pressing* or *squeezing*. *Flat-ware pressing* is performed by giving the shape to the goods by moulds which fit the *inside* of the vessel; plates, dishes, saucers, cups, and hand-basins are made on this principle by the English potter, with a dexterity which must be seen to be understood, and which excites the surprise of foreigners more than any other branch. The workman stands at a bench provided with a whirling-table similar to the thrower's, but which has its motion given by a horizontal pulley or jigger, turned by his young assistant. Close to his left hand is a *batting-block* of wet plaster, and the mass of well-beaten clay from which he is working; immediately behind him is the stove-room, in which the moulds are ranged on shelves. All being ready, the plate-maker cuts his clay into lengths with a wire, and tears off a piece which he *bats out this* upon his block by a stroke or two of his *batter*, or plaster-mallet, and polishes the surface by pressing the side of a long smooth knife across it. During this process, which occupies but a few seconds, the boy has brought a mould, placed it upon the whirler, and taken his place at the handle of the jigger. The man places the clay upon the mould, and as it whirls, presses it down close with his hand; a profile, or earthenware tool which gives the form to the bottom of the plate, is pressed upon it as it revolves, the superfluous clay being cut off by a wire; the boy instantly catches hold of the mould thus covered with a coating of clay, runs with it to the stove, places it on a shelf to dry, and returns with an empty mould; by which time his master has his clay prepared for another plate. When sufficiently hardened, the bottom of the plate is polished; and when taken off the mould, the edges are smoothed and polished with moist leather. Cups, saucers, and hand basins are now made by this process, instead of being thrown and turned as formerly. By this means they are supplied at a cheaper rate; one man and a boy being able to manufacture the articles which by the old mode requires the work of three men and three females.

Casting is resorted to when a mould is so intricate as to be difficult for the workmen to fill by pressing. Slip clay is poured into the mould, which rapidly absorbs the water, and a coating of clay is deposited upon the inside; the remaining fluid is then poured out or drawn with a syringe, and a thicker mixture is put in, and left rather longer than the first before it is withdrawn. The mould is then put into a stove to dry. Goods thus made are very light.

When completed by the workman, the goods are placed on boards to dry, before going to the biscuit-oven, in which they receive the first fire. The details of the process are described in the article already cited; and the ware, now in the state of *biscuit*, is ready for the blue-printer or for the artist, according to its quality and intended appearance.

In the old days, before the expeditious and cheapening process of electrotyping was known, a set of engraved plates for a table-service commonly cost 130*l.* or 150*l.*; and would, with proper care, print 2000 dozen services before it wanted recutting. The ink used in printing is made of linseed-oil, boiled with litharge, rosin, balsam of sulphur, or Barbadoes tar; almost every printer has his favourite recipe for making this tenacious oil, which is the vehicle of the colour to be used. *Blue* colour is made of oxide of cobalt, mingled with flint or carbonate of lime so as to dilute it to the proper tint. *Lilac*, of smalts 2 parts, manganese 1. *Brown*, zaffre 2, litharge 2, antimony 1, manganese 1. *Red-brown*, manganese 12, litharge 2, flint 2, glass 1, borax 1. *Orange*, litharge 6, antimony 4, oxide of tin 1, oxide of iron 2. *Pink*, subchromate of tin and carbonate of lime, equal parts. *Green*, oxide of chromium, the tints varied with cobalt or tin. *Black*, red-lead 60, antimony 25, manganese 15, fritted together; then add oxide of cobalt 40, oxide of tin 5.

Some patterns are executed on biscuit by painters, who lay on the colours in gum-water, in which case the firing in the muffle is not required; but the choice of colours in this kind of painting is rather limited, as the heat of the glazing-oven and the chemical action of the materials of the glaze would be destructive to many colours which are used by the enameller upon the glaze. For a description of the modes of printing and glazing, see EARTHENWARE. The following glazes are excellent, and have been successfully used in the Staffordshire potteries; they must be ground very fine at the mill. *Cream-colour glaze.*—White-lead 66, Cornish granite 22, flint 12. *Printed-ware glaze.*—White-lead 45, Cornish granite 28, flint 13, flint-glass 14. In these forms, the ingredients are simply ground together, and are therefore called raw glazes, in distinction from such as have a portion of the materials first united by calcination into a frit, or incipient glass; by this practice, a more complete combination is effected, a thinner coating of glaze will suffice, and the ware in consequence is less liable to craze with change of temperature. *Fritted glaze.*—Cornish granite 30, flint 16, red-lead 25, soda 12, borax 17; mix and calcine in the easiest part of the gloss-oven, in saggers lined with flint; then take of the frit 26, Cornish granite 15, flint-glass 10, flint 9, white-lead 40; grind the whole with a little oxide of cobalt, to increase the whiteness. *Drab-ware glaze.*—Litharge 56, Cornish granite 20, flint 24. *Blue glaze.*—Flint 40, borax 24, red-lead 16, Cornish granite 7, soda 5, oxide of tin 5, oxide of cobalt 5; calcine, then grind with the addition of a little pearl-ash. *Green glaze.*—Dissolve six pounds of sulphate of copper, and precipitate it with a solution of borax; to which add 10 quarts of white glaze. *Yellow glaze.*—Colour a white glaze with king's yellow, to the depth of tint desired; or chromate of lead. *Black glaze.*—Red-lead 74, flint 14, manganese 10, protoxide of iron 2.

We proceed to point out the chief differences between *earthenware* and *porcelain*.

Porcelain is a finer species of ware, in which the ingredients are so selected that they act chemically upon each other, and are brought to a state of vitrification. The fracture has a dense or greasy surface, like that of a flint stone, and is not liable to be acted upon by acids. When the porcelain is coloured by metallic matter, it is called *stone-ware*; jasper and some drab-ware are of this description; but when it is perfectly free from colouring matter, and is translucent, it is called *China* of which there are two species, *hard* and *soft*. It is necessary to bear in mind, however, to prevent confusion, that many writers treat *porcelain* and *china* as convertible terms, applying the former name as well as the latter to translucent ware only.

Hard china is made of silex, generally a fine sea sand, kaolin or china-clay, and felspar; sometimes the felspar is omitted, and a small quantity of selenite, or carbonate of barytes, or strontian, is used in its place.

Hard China body is made of kaolin 70, felspar 14, sand 12, selenite 4. The mixture is sometimes made in lime-water, and must be ground very fine at a mill. When the paste is moulded into the desired forms, it is fired in the biscuit-oven at a moderate heat; when taken out, it is very bibulous, and opaque. In this state it is dipped in the glaze, which is felspar, ground fine, with the addition of a little alkali. Some prefer a mixture of felspar and broken china ground together. It is then submitted to a second fire of great intensity, which not only melts the glaze on the surface, but vitrifies the entire mass, which thus unites with the softer matter on the surface so completely, that the glaze does not form a coating of glass upon the body, but appears like the surface of a stone polished by a lapidary. This homogeneity prevents any crazing; but the process is one of much hazard, for if the fire is prolonged beyond the critical moment when the vitrification is effected, and the surface has become bright, the goods will melt, and sink in the saggers. Oriental, French, and German china are made on this principle; but the English have followed the safer practice which we shall next describe, and which the French manufacturers, aware of its advantages, now adopt. *Soft or Tender China* is made by firing the biscuit to its full vitrescence in the first oven, the shape of the articles being preserved, during their vitrescence, by being imbedded in flint-powder, &c.; and then glazing in the second oven at a lower degree of heat, so as not to endanger the melting of the goods. The union between the body and the glaze is however more complete than in earthenware, the glazing-fire being much more intense. Bones calcined and ground are largely used in the manufacture of English china, combined with aluminous and silicious earths in such proportions that they will vitrify together. This effect is promoted by the phosphoric acid of the bones, which at a high heat diffuses itself through all the materials, and unites them into a translucent enamel, less apt to sink and lose its form than the hard porcelain; it therefore may be made in larger ovens, and with less risk of loss to the potter. *English China body* consists of bone 46, china clay 31, Cornish granite 23. For large pieces, such as dishes, &c., a little Dorset clay is added, to give more ductility in working and more stability in the fire; but when great purity of whiteness and transparency are wanted, a higher degree of vitrescence is obtained by fritting silex and bone together as the basis of the body. *Fritted China body* comprises bone 55, Lynn sand 27, potash 2, calcined together; then ground fine, with China clay 18. *Glaze for China* is harder than for earthenware. The following is excellent:—Cornish granite 25, soda 6, borax 3, nitre 1; mix, and frit in gloss-oven; then take frit 26, Cornish granite 26, white-lead 31, flint 7, carbonate of lime 7, oxide of tin 3. The whiteness is increased by the addition of a little oxide of cobalt. Another China glaze consists of felspar 38, Lynn sand 24, carbonate of lime 11, borax 27: to be fritted; then take frit 60, Cornish granite 20, white-lead 20.

The application of the glaze and mode of firing are the same as already described.

The decoration of china by enamel colours and gold affords employment to a great number of persons, some of whom attain great excellence in their art. The colours used are all prepared from metallic oxides, which are ground with fluxes, or fusible glasses, of various degrees of softness, suited to the peculiar colours with which they are used. The flux of most general application is made of red-lead 6, borax 4, flint 2. When painted, the goods are placed in the enamel-kiln, where the fluxed colours melt, and fasten to the glazed surface. The judicious management of these mixtures requires much study, and is still susceptible of improvement by the aid of chemical science. *Blues* are made from cobalt, varied by the addition of the oxides of zinc or tin. Phosphoric acid gives it a rich purple tint; alumina also varies its hue. *Green* is from oxide of copper, melted with a soft flux, and ground; its tints are varied by adding blue or yellow or white enamel. Fine greens, which bear a fire that destroys a copper-green, are made from protoxide of chrome, varied with the addition of cobalt, lead, tin, or alumina. *Red* consists of nitrate of iron, dichromate of lead, or muriate of manganese. *Pink*, of subchromate of tin. *Rose-colour*, of gold and tin (precipitate of cassius) with a little silver. *Brown*, of chromate of iron or antimony, lead, and manganese. *Orange*, of antimony, tin, and iron. *Yellow*, of antimony, tin, and lead; also chromate of lead. *Black*, of oxide of platinum or iron, cobalt, nickel, and antimony. *White*, of arsenic and tin. An infinite variety of tints may be obtained by a skilful combination of the above with suitable fluxes, the description of which in detail would exceed our limits. Few potters prepare their own colours; they are supplied by persons who devote themselves to that art.

Gold is applied to china in the state of amalgam ground fine in turpentine with a metallic flux. Thus, gold oxidised by being thrown in a melted state into aquafortis, 1 ounce; quicksilver 14 pennyweights, oxide of bismuth 1 pennyweight, chloride of silver 2 pennyweights. In the enamel-kiln, the bismuth and silver melt, and fix the gold to the china, without dissolving it so as to prevent its being burnished.

There has been some dispute (into which it is unnecessary to enter) as to the invention of *parian*, the beautiful biscuit-ware adopted for statuettes. The substance itself came into use about the year 1842, and is difficult to manufacture; the articles are moulded in many pieces, and shrink much during several successive firings.

Pottery.—This name is often given to the coarser kinds of red, yellow, and brown ware, such as that of which large vessels are made; but the word, like *porcelain*, is used in a very indeterminate way. Be the name what it may, however, the substance itself has become commercially of much importance. Lambeth is the head-quarters of this manufacture. What is called *Lambeth stoneware* is a vitrified body, having its surface coated with a glaze made at a very high heat by throwing salt into a hot oven; or with a glaze of silicate of soda. According to a paper read by Mr. Goddard, before the Society of Arts, in 1860, there were in Lambeth, about the year 1820, six or seven potters, having sixteen small kilns of 8 feet diameter, making about 20*l.* worth per kiln-full of blacking-bottles, ginger-beer bottles, pickle-jars, and articles of a like kind; and for some years afterwards the trade did not materially change its character. At a later date, however, when sanitary measures began to be adopted in the metropolis and other towns, a demand for stoneware drain-pipes gave a new impetus to the Lambeth potters, who have ever since made rapid advances in the scale of their manufactures. Casting in moulds and turning in the lathe are processes now much more adopted than formerly in the production of this kind of ware; as a consequence, the quality and finish of the articles are greatly improved. The Lambeth potters used to content themselves with any kind of clay that came to hand; but now the higher kind of ware demands the clays of Devon and Dorset, and a peculiar variety found near Fareham. Vessels are now made of Lambeth stoneware capable of containing 300 gallons; they are formed of layer upon layer of clay, successively and carefully applied, and each is hardened before the next is added. Filters for domestic use now constitute a large and important department of Lambeth manufactures. Drain and other pipes, condensers and worms for distilling, pumps, jugs, ladles, funnels, pans, baths, jars, druggists' pots, tobacco jars, telegraph-insulators—these are among the large number of articles made of Lambeth stoneware. There are now in this district seventy kilns, with an average capacity of 50*l.* worth of ware per kiln. One firm alone, that of Messrs. Doulton, consume about 8000 tons of coal and 8000 tons of clay annually; for it appears that, taking one kind with another, the stoneware requires about as much coal to bake it as clay to make it.

Of the commonest kinds of pottery, such as flower-pots, &c., nothing need be said; the cheapest clay and the quickest work suffice for their production.

POTTING OF PLANTS. When plants are placed to grow in a small earthen vessel, like a garden pot, their condition is very different from that to which they are naturally exposed. The roots have not liberty to extend themselves as they choose, and they are either obliged to grow back upon themselves or round the vessel in which they are confined; they are likewise exposed to great varieties of temperature and depend on an uncertain supply of moisture. It is therefore the object of the careful gardener to obviate as much as possible these evils, and at the same time to secure the advantages derived from the operation itself. These advantages consist mainly in the facility with which it enables the gardener to change the arrangement and position of his plants; it also, by cramping the roots, diminishes the tendency to form leaves, and increases the disposition to flower. It secures a constant and effective drainage from the roots, and renders it more easy to expose them to a favourable amount of bottom heat. For the raising and nourishment of young seedlings it is also an advantageous process. Exhaustion of the soil is one of the inconveniences which result from this system. In order to remedy it liquid manure should be applied; or the plants placed in *pan-feeders,* shallow earthen vessels containing manure, to which the roots have access through holes in the bottom of the pot. It is however to *shifting* more particularly that recourse should be had for renovating the soil; and this, if skilfully performed without injuring the plant, is most successful. It is not alone for the purpose of improving the soil that shifting is desirable; the roots if allowed to remain long in a confined space form a hard knotted mass, which is very unfavourable to the retention of moisture and the growth of the plant. All the earth therefore which clings to the roots should be carefully separated before the plant is placed in the fresh soil. The roots of a plant are always found to be in contact with the sides of the pot, and this being generally composed of a highly absorbent substance, is subject to great variations of temperature. The practice of plunging greenhouse plants into the earth during the summer to obviate this is very undesirable, as when they are again taken up the roots are generally found to have taken advantage of the earth around them and to have fastened themselves in it. The drainage of potted plants is of great importance, and in all cases a quantity of broken pieces of tiles and earthenware should be placed at the bottom of the pots to prevent the stagnation of water about the roots. To be managed perfectly a young plant should be placed in as small a pot as it will grow in, and gradually and successively transferred to large pots as it advances. Dr. Lindley ('Theory of Horticulture') says, "It is by paying constant attention to the shifting of the growing plant, by the employment of a very rich stimulating soil, and by a thorough knowledge of the kind of atmosphere which suits them best, that have been obtained those magnificent pelargoniums, cockscombs, and balsams, &c., that have so often and so justly excited the admiration of even the most experienced gardeners."

POULTRY, from the French *poulet.* The term includes all the domesticated birds reared for the table; fowls, turkeys, geese, ducks, and Guinea fowls.

Fowls.—"The strong and ambulatorial feet of the gallinaceous birds adapted to the region where they chiefly resort for their food and the purposes of incubation; their toes and nails peculiarly formed for scratching up the grains and seeds which constitute the main part of their subsistence; their short wings and the weakness of their pectoral muscles, which cause the heaviness of their flight, a deficiency which is counterbalanced by the strength of those muscles of the thighs and legs that contribute to their powers of running; their gregarious, and, generally speaking, polygamous habits: the ease with which they are domesticated; their wholesome flesh; together with many striking peculiarities in their anatomy, serve equally to distinguish them." (Vigors, 'Linnean Transactions,' p. 402.)

Some foreign varieties have not even the rudiment of a tail, while others are distinguished by it. The game cock, which is probably a native of India, though for many centuries established in England, has an unusual length of spur, his natural weapon of combat. The flesh of this variety is delicately white and of the finest flavour, the plumage brilliant, and the form symmetrical; but from their pugnacious temper there is great difficulty in rearing even those of the same brood; and for companionship with the general inmates of the fowl-yard they are very exceptionable for the same cause. So pugnacious however are the males of almost every variety, that they will spur even before their spurs are grown. For the natural history and peculiarities of the various varieties, we refer to PHASIANIDÆ, *Gallus,* in NAT. HIST. DIV.: we shall merely notice in this place the kinds suited to the purposes of the farmer.

The best breed of the gallinaceous fowls is the produce of the Dorking (Surrey) cock and the common dunghill fowl. This cross is larger and plumper, and more hardy than the pure Dorking, without losing delicacy of flavour or whiteness of flesh.

The characteristics of the pure Dorking are, that it is white-feathered, short-legged, large-bodied, and a fair layer. The peculiarity of this established variety, which has frequently five claws perfectly articulated (with sometimes a sixth springing laterally from the fifth, but always imperfect), is well known. The crossing with the Sussex fowl has however greatly diminished the monstrosity in the Surrey pentadactylus variety. But though the true Dorking, which is white, is much esteemed, that colour is rare, and prized for the ornament of the poultry-yard: speckled colours are most generally seen with the higgler.

The Poland breed, which is black-feathered, with white topknots, lays well, and is highly desirable where the production of eggs for the table is the principal object; but they seldom sit, though they cannot be considered long-legged.

The Chittagong, or Malay, which is a very large Indian variety, is generally long-legged, with yellow body and coarse yellow flesh. Fanciers used to like them for their fine appearance and their large eggs; but as their long legs incapacitate them from steady sitting, they are not general favourites. One of our practical acquaintances recommends the male produce of the Poland and Chittagong as a good cross with the common dunghill hen, as their progeny will sit.

The Cochin China fowl, brown or buff coloured, is a large shorter-legged bird, a constant layer, and brought largely into use of late years: its eggs are small. The Spanish or black fowl is also a constant layer of large eggs. The following on the characteristics of poultry is from the pen of a writer in a journal which has now ceased to exist, the 'Poultry Chronicle:'—

1. *Game Fowls.*—Elegant and compact in appearance, hardy in constitution, excellent caterers for themselves, good layers of delicious eggs, excellent mothers and rearers of progeny, chickens unsurpassed in flavour when dressed. The sole drawback to this prince of breeds is their disposition to fight; but I cannot say that this amounts to much, as during the time I kept them, I lost but four or five chickens from this cause.

2. *Spanish.*—Noble birds, abundant layers of very large eggs, may be kept in confined spaces more readily than other breeds, no mothers, but the chickens hardy, only wanting extra attention at about a month to six weeks old when feathering, good table-bird—should be well kept.

3. *Dorking.*—Genuine old English fowl, somewhat delicate in constitution, and seems to thrive most on warm and dry soils; eggs large and well-flavoured, but not abundant, fair mothers, chickens not so easy to rear as other breeds, splendid table-fowl where a large plump bird is preferred, wants liberal keep and warm housing.

4. *Gold and Silver Pencilled Hamburgs.*—Extremely elegant in appearance, forage well for their living, but require more feeding than the game fowl lay abundantly, but small eggs; never incubate, or

but very rarely; chickens somewhat difficult to rear, unless in very favoured spots; nice birds for eating, but small; must have a good range to keep them in health.

5. *Spangled Hamburgs.*—Very handsome, abundant layers, chickens tolerably hardy, and a very good bird for the table; their incubating qualities are seldom manifested; require a good run.

6. *Polish.*—Good layers, very elegant in form, rare incubators, chickens very delicate at first, warm housing indispensable.

7. *Cochin.*—Varied plumage, hardy, excellent eggs and more abundant than any other breed, good mothers, chickens strong, and grow rapidly under good feeding; good for table at four months old, but not after; require very liberal feeding; feathers valuable.

Those who intend to rear fowls or any kind of poultry on a large scale, should have a distinct yard, perfectly sheltered, and with a warm aspect, well fenced, secure from thieves and vermin, and sufficiently inclined to be always dry, and supplied with sand or ashes for the cocks and hens to roll in, an operation necessary to disengage their feathers from vermin: running water should be especially provided; for the want of water, of which all poultry are fond, produces constipation of the bowels and inflammatory diseases; and for geese and ducks, bathing is an indispensable luxury. A contiguous field is also necessary for free exercise, as well as for the supply of grubs and grass to the geese. The fowl-house should be dry, well-roofed, and fronting the east or south, and, if practicable, at the back of a stove or stables; warmth being conducive to health and laying, though extreme heat has the contrary effect. It should be furnished with two small lattice windows, that can be opened or shut at pleasure, at opposite ends, for ventilation, which is frequently necessary; and the perches should be so arranged, that one row of roosting fowls should not be directly above another.

M. Parmentier has shown ('Dictionnaire d'Agriculture') by what arrangement a house twenty feet long and twelve feet wide may be made to accommodate 150 hens at roost. The plan is this:—the first roosting-perch (rounded a little at the upper angles only, for gallinaceous fowls cannot keep a firm hold on perfectly cylindrical supporters) should be placed lengthways, and rest on tressels in each end wall, six feet from the front wall, and at a convenient height, which must depend on the elevation of the house from the floor, which should be formed of some well consolidated material that can be easily swept. Another perch should be fixed ladder-ways (*en échelon*) above this, but ten inches nearer to the back wall, and so on, until there are four of these perches, like the steps of a ladder when properly inclined, but with a sufficient distance between the wall and the upper one to allow the poultry-maid to stand conveniently upon when she has occasion to examine the nests, which it is her duty to do every day at least once, and in the forenoon. The highest of these she can reach by standing on a stool or step-ladder. By this contrivance the hens, when desirous of reaching the nests, have no occasion to fly, but merely to pass from one stick to another. If the size and form of the house permit, a similar construction may be made on the opposite side, care being taken to leave an open space in the middle of the room, and a sufficiently wide passage for the attendant to pass along the walls. It is not at all required to have as many nests as hens, because they have not all occasion to occupy them at the same time; and besides, they are so far from having a repugnance to lay in a common receptacle, that the sight of an egg stimulates them to lay. It is however true that the most secluded and darkest nests are those which the hens prefer.

The nests, if built into the wall, are in tiers from the bottom to the top, the lowest being about three feet from the ground, and a foot square. If the laying-chambers consist of wooden boxes, they are usually furnished with a ledge, which is very convenient for the hens when rising.

But the best receptacles for the eggs are those of basket-work, as they are cool in summer, and can easily be removed and washed. They ought to be fastened not directly to the wall, as is generally the case, but to boards fixed in it by hooks, well clinched, and with a little roof to cover the rows of baskets. They will thus be isolated, to the great satisfaction of the hen, which delights in the absence of all disturbing influences when laying. All the ranges of nests should be placed cheque-wise, in order that the inmates, when coming out, may not startle those immediately under: those designed for hatching should be near the ground (where instinct teaches the hen to choose her seat), and so arranged that the hens can easily enter them without disturbing the eggs.

Wheaten or rye straw is the most approved material for the bedding, being cooler than hay: the hens are sometimes so tortured by lice as to forsake their nests altogether, in an agony of restlessness. A Dorking housewife has assured us that she once lost an entire clutch, from having, as she believes, given a bed of hay-seeds to her sitting hen. The chicks were all glued to the shells, and thus destroyed, owing, as she thinks, to the high temperature occasioned by the fermenting seeds.

For all purposes two cocks in a good run are considered in the poultry counties contiguous to London as sufficient for twelve or fourteen hens, but in France they allow twenty mistresses to each cock, which no doubt is on account of the higher temperature there. In a confined yard, five hens are sufficient for one cock in our cold country, and a double set will not answer in very limited space. When there are two or more cocks, care should be taken not to have them of equal age or size, for in this case they are always jealous and quarrelsome; if one is decidedly ascendant, the other will never presume to dispute with him. It will be judicious also to avoid the introduction or changing of cocks in the breeding season, for the hens require constant intercourse with them, and several days frequently elapse before they become familiarised with a stranger. The best way is to bring in the new cock in the summer, either as a chick, or late in the year in the moulting season, when he will not take too much notice of the hens. As a general rule it would be well to have one a yearling, and the other a year older. In the third year, the cock, who then becomes lazy and excessively jealous, should be killed.

In order to have the earliest chickens, hens should be induced to sit in October, which they may do if they have moulted early. By attention in this particular, chickens can be brought to the market at Christmas. But the object should be in general to set the eggs as soon as possible after Christmas, in order to have chickens with the forced asparagus in March, when they are worth in London from 7*s.* to 10*s.* a couple.

In selecting eggs for hatching, care should be taken that they are not at the utmost more than a month old, but their condition for hatching will greatly depend upon the temperature of the weather: vitality continues longest when the air is cool.

It has been asserted that the future sex of the bird is indicated by the shape of the egg; the round producing the female, and the oblong the male. But this is contradicted, and, we believe, with sufficient reason; and it is impossible not only to foretell the sex, but even to ascertain whether the egg be fecundated. This however is certain, that if the air-bag (at the obtuse end), which has been mistaken for the germ, and the purpose of which is to oxygenate the blood of the chick, be perforated even in the least conceivable degree, the generating power is lost altogether. Those eggs only which have been fecundated by the male are possessed of the vital principle. The number of eggs for a hen should not exceed sixteen, as she cannot impart the necessary warmth to more. It is by no means uncommon with experienced breeders to place two hens on the same day on their respective eggs, and then on the twenty-first day, when the broods are out, to give the maternal charge of both to one of the hens, removing the other to another set of eggs, which, if she be a steady sitter, she will hatch as in the first instance. This however must be deemed a cruelty, though some hens would instinctively continue to sit until death. They would however become so attenuated by constant sitting, as to lose the power of communicating to the eggs the necessary degree of warmth. The practice of the Surrey breeders is to feed the hen on oats while sitting, as less stimulating than barley, which they give to the laying hens on account of this very quality.

Some fanciers use artificial mothers, which effect the purpose of imparting the necessary heat to the young chicks after birth, when there is no natural mother nor a trained capon to brood them. These artificial mothers—as used by Mr. Moubray, and described by him—are boxes lined throughout with wool. He recommends that a curtain of flannel should be suspended over the opening of the box for the exclusion of cold air.

Mr. Young states that "five broods may at once be cherished under an artificial mother. This mother may be framed of a board ten inches broad and fifteen inches long, resting on two legs in front, two inches in height, and on two props behind, two inches also in height. The board must be perforated with many small gimlet-holes, for the escape of the heated air, and lined with lamb's skin dressed with the wool on, and the woolly side is to come in contact with the chickens. Over three of these mothers a wicker basket is to be placed for the protection of the chickens, four feet long, two feet broad, and fourteen inches high, with a lid open, a wooden sliding bottom to draw out for cleaning, and a long narrow trough along the front, resting on two very low stools, for holding their food. Perches are to be fixed in the basket for the more advanced to roost on. A flannel curtain is to be placed in front, and at both ends of the mothers, for the chickens to run under, from which they soon learn to push outwards and inwards. These mothers, with the wicker baskets over them, are to be placed against a hot wall, at the back of the kitchen fire, or in any other warm situation where the heat shall not exceed 80 degrees of Fahrenheit.

"When the chickens are a week old, they are to be carried with the mother to a grass-plat for feeding, and kept warm by a tin tube filled with hot water, which will continue sufficiently warm for about three hours, when the hot water is to be renewed. Towards the evening the mothers are to be again placed against the hot wall."

The artificial mother, however, is only a mechanical house for chicks already hatched; but the process of bringing the embryo of organised life in the egg through all the stages of the vital principle until it becomes matured, by means of heated ovens, has been long and successfully practised in Egypt.

These ovens, which are constructed with bricks, are about nine feet high, with galleries extending through the whole length, and containing chambers into which a man can creep through a very contracted orifice for the purpose of depositing the eggs, which are laid, to the amount of several thousands, on mats or beds of flax over the brick floors. The heat is conveyed through fire-places, and the material of the slow fires, which are most effective, is the dung of cows or camels combined with straw. The fires are kept up for as many days (according to the temperature of the weather) as are sufficient to impart such a degree of heat as will continue to the expiration of the twenty-one days required for the hatching of chickens, care being taken to confine the warmth by closing up all the orifices communicating with the external air. One hundred millions of chickens are said to be thus annually produced in Egypt. For the details and statistics on this interesting subject, see the Domestic Habits of Birds, 'Library of Entertaining Knowledge,' p. 138.

M. Réaumur made various experiments in hatching with fermenting dung in hotbeds, but unsuccessfully; life was developed, but never matured: the chicks were in some cases even feathered, but long before the full time they lost vitality. He succeeded at length, "after trials enough to wear out the most enduring patience," with an oven free from the influence of the vapour exhaled from the dung, which in the previous experiments had been destructive of the embryo. He afterwards succeeded to a great degree by using a box or shelves over an oven, with due regard to uniformity of temperature. Several of the eggs in this latter case were hatched on the twentieth day, by which the usual course of nature was anticipated by one day. But though artificial hatching has long been practised with success in Egypt, it has not been found worth the expense and trouble in France, from the variableness of temperature there compared with that in the Delta, where, in the autumnal season, when the mamals (hatching-ovens) are used, it is remarkably steady and extremely warm.

As the attempt to pursue the Oriental system has failed in France, there is no probability of its succeeding in the climate of Great Britain; but it by no means follows that success may not attend such management as will obviate the obstructions which arise from irregularities of temperature. The object was indeed attained some years ago by means of the application of the Eccaleobion (from 'Εκκαλέω, "I call forth," and Βιος, "life") machinery exhibited in London by Mr. Bucknell, the inventor and proprietor. According to Mr. Bucknell, his eccaleobion possessed a perfect and absolute command over temperature from 300 degrees of Fahrenheit to that of cold water; so that any substance submitted to its influence would be uniformly acted upon over its whole surface at any required intermediate degree within the above range, and such heat maintained unaltered, without trouble or difficulty, for any length of time: and "by means of this absolute and complete command over the temperature obtained by this machine, the impregnated egg of any bird, not stale, placed within its influence at the proper degree of warmth, is, at the expiration of its natural time, elicited into life, without the possibility of failure, which is sometimes the case with eggs subjected to the caprice of their natural parent."

That chickens were thus hatched in considerable numbers is unquestionable, many thousands having been brought into existence by this single eccaleobion machine; nor was any difficulty found in the subsequent rearing of those chickens when proper yards and suitable temperature were provided, more than in the natural way; indeed in some respects less so, as the losses sustained in poultry by the sudden changes of the weather, and the influence of dampness in particular, and accidents from various causes, are very considerable. But probably, from not proving sufficiently economical for commercial purposes, the machine does not appear to have come into use.

The eccaleobion machine, capable of containing 2000 eggs, resembles an oblong box, nine feet in length, three feet in breadth, and the same in height. It has no connection with the walls, against which it is placed on the table on which it stands; its regulating power is within.*

The contemplation of the progressive stages through which life is developed and matured in the egg, is highly interesting. The contents of the shells, of the species under immediate consideration, taken out and placed on a plate or a saucer on Mr. Bucknell's table, present the following appearances, according to the respective periods:—

On the third day, the embryo organisation of the skull, brain, heart, and blood is perceptible by the aid of a magnifying glass.

Fourth day. The pulsation of the heart is distinguishable by the naked eye.

Sixth day. The chief vessels and organs rudimentally formed; the pulsation and circulation of blood apparent.

Ninth day. Intestines and veins formed, and the deposition of flesh and bony substance commenced; the beak for the first time open.

Twelfth day. The feathers have protruded, the skull has become cartilaginous, and the first voluntary movement of the chick is made.

Fifteenth day. Organs, vessels, bones, feathers, closely approaching in appearance to the natural state.

Eighteenth day. Vital mechanism nearly developed, and the first sign of life heard from the piping chick.

Twenty-first day. The chick breaks the shell, and in two or three hours is quite active and lively.

The exit of the chick from the shell is assuredly one of the most interesting processes of animated nature ever investigated by naturalists. It was supposed that the mother bird broke the shell; but M. Réaumur has long since detailed the processes, and we ourselves have witnessed the evolution of the chick in the eccaleobion by its own unassisted efforts. The French naturalist to whom we have just now referred thus explains some interesting facts:—"I have seen chicks continue at work for two days together. Some again work incessantly; others take rest at intervals, according to their physical strength. I have observed some, in consequence of their impatience to see the light, begin to break the shell a great deal too soon; for they ought, before they make their exit, to have within them provision enough to serve for twenty-four hours without taking food, and for this purpose the unconsumed portion of the yolk enters through the navel. The chick, indeed, which comes out of the shell before taking up all the yolk is certain to droop and die a few days after it is hatched. The help which I have occasionally tried to give to several of them towards their deliverance has afforded me an opportunity of observing those which had begun to break their shells before this was accomplished; and I have opened many eggs much fractured, in each of which the chick had as yet much of the yolk not absorbed. Besides, some chicks have greater obstacles to overcome than others, since all shells are not of an equal thickness nor of an equal consistence; and I think it probable that the same inequality takes place in the lining membrane. The shells of the eggs of birds of various species are of a thickness proportional to the strength of the chick that is obliged to break through them.' (Domestic Habits of Birds, 'Library of Entertaining Knowledge.')

There is a caution to be observed in all cases regarding the eggs when the chicks are on the verge of maturity: they should not be stirred when within two days of the evolvement of the chicks. If any circumstances render it absolutely necessary to do so, care should be taken to place them with the broad end inclining upwards, as the beak of the chick is then in its proper position; and if this be reversed, the chick becomes unable to chip the shell, and must therefore die.

Chickens should be fed the day after their birth with crumbs of bread soaked in milk, or with the yolk of an egg boiled hard; and they will quickly learn to eat curds, grits, and barley-meal and milk. If not designed for immediate use, they should soon get raw corn, and occasionally alteratives of green food, such as bruised leeks, nettles, lettuces, &c. For the first week they should be confined to the house altogether: after that time they may be let out for a short time in the sun, and gradually habituated to the weather. To render the hen, which has already discharged her duty, still more productive to her owner, she is frequently confined to a coop, called in Surrey a *rip*, for some weeks after the chicks have seen the light. Her offspring during this time pass freely through the prison bars, returning at her call, or on occasions of alarm, to the maternal wings, and then hopping out again, to the inexpressible misery of their imprisoned mother, who is kept in this state of confinement until she becomes indifferent to the chickens and disposed to lay again.

The courage of the hen in defence of her offspring has been a common theme of admiration; the force of her maternal solicitude effects the most surprising change in her disposition and temper. Before she attained her matronly character, she was greedy, and always searching for food, fond of gadding about, and timid in the extreme. Now she becomes generous, self-denying, and intrepid; she assumes the fiery temper of the cock, and becomes a virago in defence of her helpless brood. An anecdote is told by White, in his 'Natural History of Selborne,' of the punishment inflicted by some hens upon a hawk which had at different times killed their chickens. By some means this hawk was caught, and the owner gave him up to the tender mercies of the bereaved mothers. In his own words, "Resentment suggested the laws of retaliation. He clipped the hawk's wings, cut off his talons, and fixing a cork on his bill, threw him down among the brood hens. Imagination cannot paint the scene that ensued; the expressions that fear, rage, and revenge inspired were new, or at least such as had been unnoticed before. The exasperated matrons upbraided, they execrated, they insulted, they triumphed. In a word, they never desisted from buffeting their adversary till they had torn him in a hundred pieces."

Poultry are the better for high feeding from the very shell, and on this account the heaviest corn is often far cheaper for them in the end than tailings, as regards the flesh, or the size and substantial goodness of the eggs. Young chickens may be put up for feeding as soon as the hen has ceased to regard them, and before they lose their first good condition. When chickens are wanted for domestic purposes, they are often left at liberty in the farm-yard, and if they have plenty of good food, they will be in the most healthful state for the table, and rich and juicy in flavour. Mr. Moubray ascertained that pullets hatched in March, if constantly high fed, laid eggs abundantly in the autumn; and if killed in the February or March following, were so excessively fat from the run of the yard as to open more like Michaelmas geese than chickens. Experienced poulterers will fatten fowls in two or three weeks with the aid of grease, which gives a luscious, but, in our judgment, a very disagreeable flavour to the flesh, which, though not actually diseased, is very inferior to that of the fowl fed at large in the common way at the barn door.

The practice of cramming poultry by the hand is quite common. A machine for this purpose is used in France, by which one man can cram fifty birds in half an hour. It is somewhat on the principle of a forcing-pump. The throats of the birds are held open by the operator until they are gorged through a pipe, which conveys the food from a reservoir below placed on a stool. In fifteen days, fowls are said to attain the highest state of fatness and flavour by this feeding. In addition to the ordinary paste of barley-meal, or meal made into little balls with milk, the dried seeds and leaves of nettles have been recommended by the continental poulterers, some of whom give a little henbane-seed to induce sleep, while others put out the eyes of the prisoners as the most effectual way of keeping them in a state of darkness, which is considered essential to their becoming rapidly fat; and under the pretext of relieving them from the irritation of vermin, they pluck the feathers from their heads, bellies, and wings. While fowls are thus preparing for the knife, though their bodies are closely confined, their hinder parts are free for evacuation and cleanliness, and their heads are at liberty to take in fresh supplies of nutriment.

---

* 'Treatise on Artificial Incubation,' by W. Bucknell, Esq., p. 36.

The practice of making capons (emasculating the males) is practised a little in some of the English counties, and very much in France, where the females are also rendered incapable of breeding, and termed in their unsexed condition *poulardes*, in order to give them the tendency to fatten. An incision is made near the parts, and through this the finger is introduced to take hold of and bring away the genitals, but so carefully as not to injure the intestines: the wound is then stitched up and rubbed with oil or grease; and the comb (which appears to be an unnecessary and gratuitous pain and insult to the sufferer) is often cut off. The females are treated much in the same way, when they do not promise well for laying, or when they have ceased to be fertile; they are deprived of the ovarium. The subsequent treatment is similar to that in the former case. Care is taken to give them good food for three or four days, and during that time to keep them in a place of moderate temperature, to avoid the danger of gangrene, which, considering the time of the year—midsummer, when the operation is usually performed—is a very probable consequence. Pullets of the largest breed are selected for the purpose, as they yield the greatest weight to the poulterer; and if employed in hatching, cover the greatest number of eggs.

Cuvier states that the capon may be taught to hatch eggs and to act the part of a good nurse, with a little bell round his neck to supply the want of a good voice. He asserts that the natural courage and energy of this bird are not abated by the alteration of his condition, in which his audacity enables him to impose on the cocks and hens, so that they allow him to strut about with his former gait of consequential importance, and to fulfil his duties without interference or molestation. This seems incredible, as a bold and haughty spirit under such circumstances is unnatural in the extreme. The pallidness of his head and the diminutiveness of his comb and gills indicate the contrary disposition, and he is so despised by the other fowls that they will hardly condescend to roost with him.

Mr. Young, in his 'Report of the County of Sussex,' says that much art and attention are requisite to make capons, and that the Sussex breed are too long in the body for success in the operation, by which many are lost. A perfectly fat capon will weigh from seven to ten pounds.

As soon as the fowls are rendered sufficiently fat, they should be killed, or they will lose flesh and become unhealthy. The most humane and expeditious mode of putting them to death is by a smart blow with a blunt-edged stick, such as a child's bat, at the back of the neck. Higglers break the vertebræ of the neck by a sudden twist, and never bleed fowls, as this mode of dispatching them dries up the juices of the flesh. They bleed turkeys and geese however, after a stunning blow in the neck, not by cutting the throat, but by an incision in the upper part of the mouth.

Store fowls will feed well upon the tailings of corn, potatoes, and insects, and require little attention except when laying, during which time the food for the hens should be abundant, and their roosting-places dry and warm.

The diseases of all poultry principally arise from cold and moisture. Rheumatism decidedly arises from this cause. During or after moulting in a wet season, fowls frequently become diseased, as is evident from their drooping appearance, swelled and watery eyes, and the dropsical affections of the legs. Severe laying also sometimes causes emaciation and illness, which give way to a more healthy condition after the moulting season, if they have good food and dry weather.

Chickens are very subject, in wet or variable weather, to a disease called the chip, which appears in about a fortnight after their birth, when they are changing their feathers. Warmth and sunshine are the only restoratives within our knowledge.

The roup is properly an imposthume upon the rump, which is cured or relieved by opening, squeezing, and bathing with warm water. Mr. Moubray, however, who is a good practical authority, states that the roup is a general term for all diseases, though it is generally applied to catarrh, which is indicated by watery eyes and running at the nostrils. This last disease resembles glanders in horses, and is infectious, and generally fatal. As all these diseases originate in moisture, dryness and warmth are the best counteracting influences. The nostrils should be washed with soap and water, and the eyes with milk and water. Mr. Moubray recommends a pepper-corn in dough at first to impart warmth, and afterwards calomel three times a week as a finish to the cure.

We have had the trachea of a chicken dying of the gapes (which is the incipient stage of roup) cut and opened, and have taken out narrow worms, about half an inch in length, which lay imbedded in a serous fluid. We have known fowls to be cured of the same disease by putting the upper part of a feather, stripped for the purpose, down the trachea, turning it round, and thus bringing up the worm.

The pip, which is probably a modification of roup, has been cured by an application of powdered borax dissolved in tincture of myrrh and water, and rubbed on the tongue with a camel-hair brush two or three times a day. This at the same time assists the bowels. The flux is not uncommon. Solid corn is the most certain remedy for this disease. Taken at the commencement, it is rarely serious, but if once established in the constitution it becomes incurable, and, according to some, contagious. For constipation, bran or pollard, with milk, beet leaves, and lettuces, afford a certain cure.

Much of the foregoing matter applies to the rearing and management of all poultry. The succeeding observations will be brief.

Turkeys.—The greatest weight to which our domesticated poultry can be made to attain is 30lbs., and a turkey of even half this weight is "a dainty dish."

"The varied plumage of the bird in the domesticated state is well known to every one; and in no species is that sure mark of subjection to man more strongly seen. Every gradation of colour, from its original bronze, passing into buff, and in many instances into pure white, may be observed in these strutting denizens of our farmyards." (Broderip, 'Recreations in Natural History.') The bronze or copper-coloured is not considered hardy, nor is it often reared, and the varieties may be stated to be only twofold, the dark-coloured and the light.

The dark-coloured birds are most prized for size and hardihood. Notwithstanding the great price which may be obtained for turkeys in London when fat, the finest young birds may be purchased in Ireland, fit for cramming, in September and October, from 4*s.* to 5*s.* a couple, and the light-coloured and smaller ones frequently from 2*s.* 6*d.* to 3*s.* 6*d.* a couple.

Turkeys, though extremely delicate in their infancy, become very hardy, and, if permitted, will roost on the highest trees, in the cold dry nights of winter, without suffering injury. The hen, which lays many eggs early in spring, sits thirty days, and covers from twelve to fifteen eggs. It is unnecessary for the turkey cock, as is the case with gallinaceous fowl, to be in constant intercourse with the hen during her period of laying. Two visits from him in that season are sufficient to impregnate all the eggs. She is a very steady sitter, and must be removed to her food and supplied with water, for she would never leave her nest. She wants the alertness and courage and sagacity of the common hen, and might be called a fool with much more propriety than the goose, which is an intelligent bird. The turkey hen is incapable of teaching her young ones how to pick up their food, on which account a poultry-maid should always attend them until they are reared.

On account of the constitutional delicacy of this bird, the hatching should not be commenced too early in the spring, and when the chicks are hatched they should be guarded from the extremes of heat and cold for some weeks. Rain is almost always fatal to them in their early stage. Curd, boiled eggs, and barley or oatmeal, kneaded with milk (or water, in case milk should produce looseness), potatoes, nettles, parsley, Swedish turnips, with chopped beet leaves, after a little time, is their proper food. As they retain so much of their original wild nature as to stray a considerable distance, if permitted, the hen should be tied or cooped for at least six weeks, when the chicks will be hardy enough to follow her about, under the vigilant eye however of the poultry-maid, who should beware of their being caught by a shower.

They are soon familiarised to the society of fowls in the poultry or farm-yard. Without the advantage of the latter, it is an unprofitable speculation to rear any description of poultry on a large scale; but where a farmer's yard presents facilities, the economy of having all those kinds to which the soil and climate are suitable, is considerable. The only caution with regard to turkeys, where gallinaceous birds are numerous, is to have separate houses for them at night. These should be very lofty and well ventilated. They may be altogether open to the air in front, the doors being of trellis-work. Fowls (which are equally unsocial with the capons of their own kind) have a strong disinclination to roost with them.

When well-grown, turkeys supply themselves in their ramblings so far as to require food only when leaving their house in the morning and returning at night. The chances of rearing a second brood are not so great as to render it expedient to make the trial.

After six months turkeys may be crammed like fowls, but they require a much longer period to render them fully fat. Those great birds which are sent to the London market about Christmas, principally from Norfolk, frequently weighing from twenty to twenty-five pounds, are usually cocks from the preceding year. Great numbers of turkeys are reared in Ireland, where the climate is congenial to their nature.

Guinea Fowl.—This bird, which is not much larger than the common barn-door fowl, is of beautiful form and plumage, and though not a source of profit to the peasant who rears poultry for immediate sale, is usually kept where there is proper accommodation, as much on account of the excellence and abundance of the eggs (which, though small, are well-flavoured) as for the sake of the flesh, which is prized in the London markets when the season of pheasant-eating ceases. The number of hens allowed to the male is about the same as among the gallinaceous family. The cock, little distinguished in appearance from the female, is an attentive and affectionate mate, and even obtrusively so to his favourites, whom he will attend to the nest, and remain with until they have laid their eggs.

Retaining some of their original wildness, Guinea fowl dislike the confinement of a house. For the purpose of laying, they prefer shrubberies, clover-meadows, or corn-fields, in which they will deposit their eggs, unless closely watched. The Guinea hen is fruitful during the entire summer, but not earlier than May. On this account, and the difficulty of rearing a late brood, it is more beneficial to keep her entirely for laying, and to put the earlier eggs under a common hen or capon, which will cover from twenty to twenty-five, than to encourage the incubation of the natural parent, which is moreover indisposed to it, especially if under cover. If left to her instinct, this bird would at a late season, in the open air, sit for the natural period, which is twenty-eight or twenty-nine days.

The cock, having the same dislike to incubation which characterises the male of pea-fowl, will destroy the eggs if he can discover them. Though the shell is remarkably hard, the chicks break through it at the proper moment, and are soon after as vigorous and ready to eat as the young of any other tribe of poultry.

The loud cry of these birds is not agreeable, but, like the scream of the pea-fowl, it announces with certainty an approaching change of weather. The hen utters a cry when she desires to roost, to call in her companions, to summon assistance, or to give notice of any of those alarms which her sensibilities cause her to express with such energy of voice, and in all which cases she is sure of receiving a ready sympathy.

The same food which is suited to the young of gallinaceous fowls and turkeys is good for the chicks of this kind; but as they are not often destined to the coops for fattening, a good deal of garden or field green-food may be combined with their grits, &c., after the first month. They have a great relish for insects of every kind, and thrive upon them as well as upon hemp-seed. When designed for the table, they ought to be killed at an early age, at which time the flesh is more juicy than that of other poultry of the same age, and very like that of the pheasant, though when old it becomes exceedingly tough.

Ducks.—The white duck, being the largest of the common domesticated kinds, is perhaps the best for the poulterer, though it is not deemed so delicate in flavour as the dark-coloured, such as that bred from intermixture with the Rhone duck, which is also large. The Muscovy variety is said to be a good breeder. One drake is sufficient for five females. It is generally believed that the duck lays no more eggs than she can cover (from twelve to fifteen), but Mr. Moubray states that, if well fed, some ducks will lay a great number, and he gives an instance of one laying an egg every day for eighty-five days.

For a fortnight after their birth ducklings should be kept from rushing into water, to which their instinct soon leads them; and with this view the mother is frequently confined (where there is any pond within her reach) to the rip, already described, which should be placed on a field of short grass, with a flat dish of water near it. The ducklings waddle about in search of insects, and at the maternal call return to the coop. This restraint upon the liberty of the poor mother should be avoided if circumstances permit, for to protract her close confinement after more than four weeks' sitting is a cruel restraint. It is very common to place duck-eggs under a hen, on account of her excellent qualities as a nurse.

Any kind of meal is good for ducklings at first, and this may soon be mixed with potatoes. The refuse of the kitchen will not only support but fatten them; but to have them quickly and highly fattened, they should have oatmeal made into paste. They will also devour any animal offal, and have no fastidiousness whatever. If allowed to follow a plough or attend on the gardener when his spade is at work, their greediness and activity in picking up worms are extreme; and for gobbling up snails and slugs and other such delicacies in the field or garden they are most useful, while they are at the same time putting themselves into high condition. Having no fastidiousness of appetite, they never require cramming, indeed they act as though they considered it their duty to get fat as quickly as possible, and therefore required no artificial aid.

In a poultry-yard the ducks and geese are frequently lodged on the lower floor of the fowl-houses, but it is better, if the locality will permit, to give them distinct chambers, particularly where a good pond (free from eels) is available; on the margin of this their huts may be placed with very trifling labour, and an invisible paling all round the water, constructed at bottom on the principle of the cage-trap, so as to prevent the ingress of rats or weasels, while it affords them a ready outlet, renders this department of the poultry establishment complete, though far too expensive for common adoption.

"Many families in Bucks derive a comfortable living from breeding and rearing ducks, the greater part of which, the early ones at all events, are actually brought up by hand. The interior of the cottages of those who follow the occupation presents a very curious appearance to the stranger, being furnished with boxes, pens, &c., arranged round the walls for the protection of the tender charge of the good wife, whose whole time and attention are taken up with this branch of domestic economy." (Moubray.)

Geese.—The proportion of females to the males is the same as in the duck tribe, and the period of incubation and the number of eggs that may be set correspond exactly. The goose lays in a mild spring very early, and on this account (but only with high corn-feeding in the previous winter, and stimulating food during the entire breeding season) two broods may be had in the same year. Unlike the peacock and the Guinea cock, the gander is not only indisposed to do any mischief to the nests, but is very attentive to the hatching birds, whom he vigilantly protects as he sits patiently by; nor is his protection, as he accompanies the goslings in due course, less creditable to his parental character. The goose is a very steady sitter, but usually rises often enough to drink and take sustenance, without its being necessary to remove her from the nest for the purpose.

The early treatment of the goslings is similar to that of ducklings. The mother should be penned up for some days upon dry grass, but neither too early nor very late in the day; beet leaves or other green food may be mixed even with the early diet, if immediate fattening be not the object.

Green geese are brought very early to the London market, and are worth at first from 8*s.* to 12*s.* each; they can be made quite fat with oatmeal and peas, and skimmed milk or butter-milk, when from four to six months old: many prefer oats alone.

The management of them in the vicinity of London is thus detailed in a communication to Mr. Moubray:—

"Cleanliness, punctuality, and regularity prevail; the business is conducted as it were by machinery, rivalling the vibrations of the pendulum in uniformity of movement. The grand object of preparing, not geese only, but poultry in general, for market, in as short a time as possible, is effected solely by paying unremitting attention to their wants; in keeping them thoroughly clean; in supplying them with proper food (dry, soft, and green), water, exercise ground, &c. On arriving at the feeder's, they are classed according to condition, &c.: they soon become reconciled to their new abode, and to each other. They are fed three times a day; and it is truly astonishing how soon they acquire the knowledge of the precise time; marching from the exercise ground to the pens like soldiers in close column. Goslings, or young geese, come to hand generally about the month of March, after which a regular and constant supply arrives weekly throughout the season. At first they are fed on soft meat, consisting of prime barley or oat meal, afterwards on dry corn. An idea prevails with many that any sort of corn will do for poultry: this is a grand mistake. Those who feed largely know better, and invariably make it a rule to buy the best. The Messrs. Boyce, of Stratford, whose pens are capable of holding the extraordinary number of four thousand geese, independent of ducks, turkeys, &c., consume twenty coombs of oats daily, exclusive of other food."

But though green geese bring an enormous price in the spring, if thoroughly fat, farmers generally find it more profitable to feed goslings on the stubbles, where they supply themselves with the best food without cost, and become sufficiently fat at Michaelmas, when ancient custom renders them a favourite dish. In the neighbourhood of the extensive commons in England great numbers of geese are kept.

Though young geese are subject to a disease called the cramp, the greater number of those which die in summer are destroyed by starvation, and the change from corn, and other nutritive food, to the miserable herbage which the fields and commons yield; and this constitutes their chief diet until the harvest season. Cold and wet weather are often fatal to them in the earlier months, if they be neglected. Much mortality also prevails amongst grown geese, wherever the horrible system of plucking them alive prevails, as in Lincolnshire and in Ireland. It is generally urged in excuse for this barbarity, that feathers are most elastic and valuable before the period of moulting, and that geese have been thus treated ever since feather-beds came into fashion. The offence carries some punishment with it; for it renders the flesh very tough, and in many respects deteriorates the value of a bird, if it does not destroy it altogether; but the immediate gain from the feathers counterbalances this and every humane consideration.

The cramming system is practised in France, when the object is to render the liver unnaturally enlarged by disease, with circumstances of great cruelty. We do not intend to give any information upon practices which we cannot recommend, and which we strongly condemn.

Eggs.—The most certain way of preserving eggs fresh is by greasing them with some unctuous matter, or immersing them in a strong solution of lime. In packing, they should be laid on end; for otherwise the yolks, preserving their centre of gravity, fall to the lowest side, and by adhesion to it become tainted sooner than if they were suspended in the centre. [Egg Trade.]

The only management, besides warmth and high feeding, by which a perpetual succession of eggs can be obtained in winter, is by having pullets and hens of different ages, which, moulting at different periods, are not all incapacitated from laying contemporaneously.

POUND. [Standard of Weight.]

POUNDAGE. [Subsidy.]

POWER. In Factorials, the manner in which the term *power* was introduced into arithmetic is seen. By definition, the fourth power of x means the product of four $x$es, or $x \times x \times x \times x$; and the same of other powers. But it is far more symmetrical to begin from unity;

and to say that the fourth power of x is the result of four multiplications by x, unity being understood as the commencement. Thus the successive powers of x, first, second, third, &c., are $1 \times x$, $1 \times x \times x$, $1 \times x \times x \times x$, &c.: denoted by x^1, x^2, x^3, &c. And the term *root* is the inverse of power, as follows: If A be the mth power of B, B is the mth root of A, denoted by $\sqrt[m]{A}$. The peculiar algebraical character of the roots is explained in ROOT.

It is thus easily proved that when m and n are any two integers,

$$x^m \times x^n = x^{m+n};$$

that when m is greater than n,

$$x^m \div x^n = x^{m-n}.$$

$$\text{Also that } x^m \times y^m = (xy)^m,$$

$$(x^m)^n = x^{mn},$$

$$\text{and that } \sqrt[n]{x^m} = x^{\frac{m}{n}},$$

whenever m is divisible by n without remainder. These rules, if applied in defiance of the restrictions first mentioned, lead to such results

$$\text{as } x^0,\ x^{\frac{1}{2}},\ x^{-4},\ x^{-\frac{1}{2}},\ \&c.,$$

which are unintelligible so far as the definitions have yet been stated. Their proper interpretations [INTERPRETATION] are as follows: First, x^0 must be allowed to stand for unity, whatever x may be; secondly, x^{-n} must be understood to be $1 \div x^n$; thirdly, $x^{\frac{m}{n}}$, m and n being positive integers, must stand for $\sqrt[n]{x^m}$. When these new definitions are added, all the rules remain true, whether m and n be positive or negative, integral or fractional: and the system of algebraic powers is complete.

An algebraic expression is said to be arranged in powers of a letter, say x, when the powers of that letter which enter are made to enter in ascending or descending order of algebraic magnitude. Thus $ax^2 + bx^{-3} - x^4 - x^{-1}$ is not at present arranged at all. To arrange it in ascending or descending powers of x, we must write it thus—

$$bx^{-3} - x^{-1} + ax^2 - x^4, \text{ ascending;}$$

$$-x^4 + ax^2 - x^{-1} + bx^{-3}, \text{ descending.}$$

But even yet it is incomplete for many algebraical purposes, having no written indication of the fact that the ascent or descent is interrupted. Completely written in ascending powers, it should be

$$bx^{-3} + 0x^{-2} - x^{-1} + 0x^0 + 0x^1 + ax^2 + 0x^3 - x^4.$$

Written in this form, which may remind us of the use of a cipher in writing ordinary numbers, it is clear that we hardly read the expression less easily, and write it much more briefly, if we omit x and its powers altogether, and make some distinctive mark, analogous to the decimal point, between the parts which belong to the positive and negative powers. Thus the above might be written—

$$b + 0 - 1 + \mid 0 + 0 + a + 0 - 1,$$

$$\text{or } \ -1 + 0 + a + 0 + 0 \mid -1 + 0 + b;$$

the mark | being on that side of the adjacent + or — which belongs to the positive powers. This mark however is not necessary in what follows.

The late Mr. Horner [INVOLUTION, &c.] was the first who suggested the systematic rejection of the ascending or descending powers. An example of multiplication and division will sufficiently explain its use. Suppose it required to multiply $7x^3 - 2x^2 - 3$ and $2x^4 + x^3 - 4x - 5$:—

$$\begin{array}{rrrrrrrr}
2 & +0 & +1 & -4 & -5 & & & \\
7 & -2 & +0 & -3 & & & & \\
\hline
14 & +0 & +7 & -28 & -35 & & & \\
 & -4 & +0 & -2 & +8 & +10 & & \\
 & & & -6 & +0 & -3 & +12 & +15 \\
\hline
14 & -4 & +7 & -36 & -27 & +7 & +12 & +15
\end{array}$$

Accordingly the answer is $14x^7 - 4x^6 + 7x^5 - 36x^4 - 27x^3 + 7x^2 + 12x + 15$; and every stroke of the pen which the usual method contains, more than is in the preceding, is mere waste, and risk of error into the bargain. Now let it be proposed to divide $4x^6 - 3ax^5 + 2a^2x^4 - 11a^5x - a^6$ by $x^3 + 2ax^2 - a^3$:—

$$\begin{array}{rrrrrrrl}
4 & -3 & +2 & +0 & +0 & -11 & -1 & (1+2+0-1 \\
4 & +8 & +0 & -4 & & & & \quad 4-11+24-44 \\
\cline{1-4}
 & -11 & +2 & +4 & +0 & & & \\
 & -11 & -22 & +0 & +11 & & & \\
\cline{2-5}
 & & 24 & +4 & -11 & -11 & & \\
 & & 24 & +48 & +0 & -24 & & \\
\cline{3-6}
 & & & -44 & -11 & +13 & -1 & \\
 & & & -44 & -88 & +0 & +44 & \\
\cline{4-7}
 & & & & 77 & +13 & -45 &
\end{array}$$

Accordingly the quotient is $4x^3 - 11ax^2 + 24a^2x - 44a^3$, and the remainder is $77x^2 + 13ax - 45a^2$.

Mr. Horner himself did not live to print this suggestion, which, simple as it is, seems never to have been made before him. The possessor of his papers, Mr. T. S. Davies, of Woolwich, published some extracts from those papers in an appendix to a reprint of the paper on the solution of equations, which reprint appeared in the 'Ladies' Diary' for 1838; having previously introduced the simplification into the 11th edition of Hutton's Course. Since that time a paper on 'Algebraical Transformation,' sent by Mr. Horner to the Royal Society, but not * printed in the 'Philosophical Transactions,' has been published in the first and second volume of the 'Mathematician.' Details and examples are given in Mr. Davies' 'Solutions of Questions contained in Hutton's Course,' 1840, and in the 12th edition of that course, 1841.

But the greatest improvement in the operation of division, and one which contains the principle of a class of improvements, is one which Horner called the *synthetic method*, which amounts to deferring the actual steps of subtraction until they are wanted. If we were to proceed one step farther with the preceding division, −44 in the quotient would be followed by +77. This +77, if we look at all its components from the beginning, arises from $+0 - 11 - 0 + 88$. In like manner -44 arises from $+0 + 4 - 0 - 48$. Now arrange the process as follows:—

$$\begin{array}{r|rrrrrrr}
\underline{1} & 4 & -3 & +2 & +0 & +0 & -11 & -1 \\
-2 & & -8 & +0 & +4 & -11 & +24 & -44 \\
+0 & & & +22 & +0 & +0 & +0 & \\
+1 & & & & -48 & +88 & & \\
\hline
 & 4 & -11 & +24 & -44 \mid & +77 & +13 & -45
\end{array}$$

Write the coefficients of the dividend horizontally a, b, c, &c., and of the divisor vertically p, q, r, &c., taking care to change the sign of every term of the divisor *except the first*.

$$\begin{array}{r|ccccccccc}
\underline{p} & a & +b & +c & +d & +e & +f & +g & +h & \\
+q & & +uq & +ur & +us & +ut & +vt & +wt & +xt & +yt \\
+r & & & +vq & +vr & +vs & +ws & +xs & +ys & \\
+s & & & & +wq & +wr & +xr & +yr & & \\
+t & & & & & +xq & +yq & & & \\
\hline
 & u & +v & +w & +x & +y \mid & +u' & +v' & +w' & +x'
\end{array}$$

Divide a by p, giving u, and then write uq, ur, us, and ut in the successive columns which follow that of u. Make up $+b+uq$, the second column, and divide by p, giving v: write vq, vr, vs, vt, in the successive columns which follow that of v. Make up $c + ur + vq$ and divide by p, giving w: write wq, wr, ws, wt, in the columns which follow that of w, and so on. Then $u + v + w +$, &c., will give the coefficients of the quotient, and $u' + v' +$, &c., made from the columns which have not been used to find quotient terms, will give the coefficients of the remainder. For example, we want to find some terms of the quotient of $x^4 + 1$ divided by $x^3 + x^2 - 3x$:—

$$\begin{array}{r|rrrrrrrr}
\underline{1} & 1 & +0 & +0 & +0 & +1 & & & \\
-1 & & -1 & +3 & +0 & +0 & +0 & +0 & +0 \\
+3 & & & +1 & -3 & +12 & -21 & +60 & \\
+0 & & & & -4 & +7 & -20 & & \\
\hline
 & 1 & -1 & +4 & -7 & +20 \mid & -41 & +60 & +0
\end{array}$$

Hence the quotient is $x - 1 + 4x^{-1} - 7x^{-2} + 20x^{-3}$, and the remainder is $-41x^{-1} + 60x^{-3}$.

When the first coefficient is anything but unity, fractions are introduced into the quotient. To avoid this, proceed as follows: Let a be the coefficient of the first term of the divisor. Multiply the successive coefficients of the dividend by $1, a, a^2, a^3$, &c.: turn the first coefficient of the divisor into 1, and multiply the second, third, fourth, &c., by $1, a, a^2$, &c. Proceed as above with the coefficients thus altered, and suppose that in the last line the quotient terms become $u + v + w +$, &c., and those for the remainder $u' + v' +$, &c. To find the true quotient coefficients write

$$\frac{u}{a} + \frac{v}{a^2} + \frac{w}{a^3} + \ \&c.,$$

---

* The Royal Society has been very unfortunate in its decisions about papers involving improvement of calculation. Horner's paper on equations was nearly rejected, and was only saved by the earnest remonstrance of Mr. Davies Gilbert. Barrett's improvement of life contingency calculations was rejected; so was Weddle's remarkable paper (afterwards published by himself) on the solution of equations by successive factors. Horner's paper on transformation was *withdrawn*, not rejected. The report on it set forth that Mr. Horner had proved himself the most able and the most dexterous of all who had recently investigated the solution of equations; but there was a doubt as to the methods of the paper being so much better than others, and possessing so much of novelty, as to fit them for the Transactions. The council were embarrassed: they could neither reject nor accept the paper; so they suggested that it should be withdrawn. It seems then that *better* methods than any in use were not fit for the Phil. Trans., unless the superiority was very decided. Now, first, this was a very unsound principle, and very unworthy of a scientific body; secondly, Mr. Horner's methods *do* possess a very decided superiority, as all who have used them know.

and for the true remainder coefficients write

$$\frac{u'}{a^m}+\frac{v'}{a^{m+1}}+\text{\&c.},$$

where a^m is the last power used in the quotient terms, *repeated*, not the next one to it. Suppose, for example, we are to divide $x^3+mx^2+m^2x+5m^3$ by $2x^4+m^2x^3-3m^4$. Here, since x descends and m ascends regularly, we throw out x and m, and the abridged dividend and divisor become

$$\begin{array}{ccc} 1+1+1+5 & \text{and} & 2+0+1+0-3 \\ 1\quad 2\quad 4\quad 8 & & 1\quad 2\quad 4\quad 8 \end{array}$$

underneath which we have written the multipliers. Hence we begin with $1+2+4+40$ and $1+0-2+0-24$:

$$\begin{array}{r|l} 1 & 1+2+4+40 \\ \hline +0 & +0-2+0+24+48+48+864 \\ -2 & \quad +0-4+0+0+0 \\ +0 & \qquad +0-4-72 \\ +24 & \qquad\quad +0 \\ \hline & 1+2+2+36 \mid +20-24+48+864 \end{array}$$

Hence the quotient is

$$\frac{1}{2}\frac{1}{x}+\frac{2}{4}\frac{m}{x^2}+\frac{2}{8}\frac{m^2}{x^3}+\frac{36}{16}\frac{m^3}{x^4}$$

and the remainder is

$$\frac{20}{16}\frac{m^4}{x}-\frac{24}{32}\frac{m^5}{x^2}+\frac{48}{64}\frac{m^6}{x^3}+\frac{864}{128}\frac{m^7}{x^4}$$

One of the easiest modifications of this rule is the division of $ax^m+bx^{m-1}+\ldots$ by $x-p$ or $x+p$, as explained in FRACTIONS, DECOMPOSITION OF.

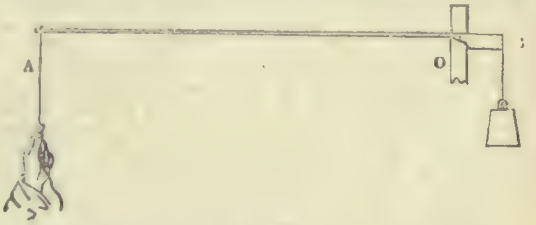
POWER (Mechanics). The present article is not intended to enter deeply into the subject, but only to remove various fallacies connected with the use of the word *power*, which frequently perplex and confuse those who attempt to study mechanics without the aid of mathematics.

The word *power* has obtained a technical meaning which seems to be almost peculiar to popular treatises. From among the numerous combinations which occur in machinery, the lever, the inclined plane, the wheel and axle, the pulley, and the screw have been selected, and named *mechanical powers*. Some have treated these as different principles; some have asserted that they are reducible to the lever and the inclined plane, others to the lever only; but it is generally asserted that all mechanical contrivance is reducible to one or other of these. To which of them the very powerful machine (in its way) which men call a *cannon* is to be referred we do not know, not seeing any great likeness in it either to a lever, an inclined plane, a wheel and axle, a pulley, or a screw. Again, the notions of the theories of these powers are as various as those of their arrangement: some say that all are creators of power, some that all are powers except the simple pulley, some that none are powers, some that they are losses of power. Those who deny that any of the adaptations above mentioned give power, look for their meaning of the word in the action of what are thence called *agents*, as in the muscular strength of men and animals, the force of wind, the fall of water, the expansion of steam or explosive gases, &c. Admitting that all these agents are well entitled to the name of powers, it is nevertheless difficult to refuse that name to a machine. Watch the effect of a large crane in unloading a vessel, compare it with what the same men could do by their unaided (or rather, unadapted) strength in the same time, and it will be impossible to deny that the machine gives power.

The cause of all this confusion and diversity of opinion as to the way of stating facts which every one knows, arises from the word power being taken in two different senses, that which is true of one of its meanings being untrue of another. In the first sense, power is gained whenever any thing is done quicker or better at the same expense, or in as effective a manner at less expense; whenever the advantage gained, or the disadvantage avoided, is worth more than the trouble and cost of the means employed. In the second sense, power is gained when a new adaptation is introduced, by which an existing agent is made apparently stronger. To find different phrases for these different things, let us say that power in the first sense means that which produces beneficial effect, and that power in the second sense means that which produces mechanical advantage: these last words have been often used by writers in the same sense as the technical word power.

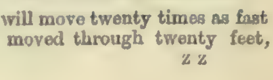
Beneficial effect may be produced in various ways, without mechanical advantage, but the benefit, as far as it is of a physical character, will generally be found to consist in a saving of useless labour. Thus, in the division of labour, than which nothing produces more of beneficial effect, there is not only the moral benefit, namely, the making the human agent fitter for his work by giving him a more limited range of occupations, but the actual saving of the labour of laying down one tool and taking up another. Again, when loaded carriages are dismissed down an inclined plane and made to draw up the empty ones, there is no gain in a mechanical point of view, for the momentum which is gained by the empty carriages is lost by the loaded ones; but the momentum lost by the loaded carriages is no loss, since there is no use in their delivering their contents with a great velocity, while the momentum abstracted is applied to a beneficial purpose. Thirdly, a simple pulley gives no mechanical advantage whatever, since the weight on one side, when the pulley is at rest, must be equal to that on the other. If however we compare the effect of this machine in raising weights with the carriage of them up a ladder, we see at once a beneficial effect, amounting to a saving of the greater part of the labour; for by using a pulley, the labourer has not to carry himself up to the height required and down again. Fourthly, when the traces by which horses draw are inclined at a proper angle, a part of the drawing power is taken off, and applied in lifting the carriage off the road and lessening the friction, so that the diminished draught is better able to do the remaining work than if the whole draught were applied to the whole friction. Here is no gain of power in the mechanical sense, though the alteration is certainly a double gain (no matter how slight a one) of beneficial effect, for the carriage is more easily drawn and the road is less worn. Numberless instances might be cited in which real benefit is a consequence of mere adaptation, even without the production of what is called *power* in treatises on mechanics.

In treating of the second meaning of the word power, or its synonyme, mechanical advantage, we must separately consider a machine just balanced, and one in which an additional force applied gives motion. Suppose a lever, one arm of which O A is ten times as long as the other O B, and suppose that the arms balance each other. A pull of one pound at A will then support (so it seems) ten pounds at B, for the first will certainly equilibrate the second, or prevent motion. Nevertheless, it is not true that one pound supports ten pounds; nor can one pound, by any contrivance whatsoever, be made to support more than one pound. In the case before us, A acts against one pound, but not one pound of B; it is A and B together, eleven pounds in all, which oppose a resistance of eleven pounds offered by the support or pivot O. The weight B is equivalent to two pressures, one downwards, at O, of eleven pounds, one upwards at A, of one pound. The frame on which the pivot rests neutralises the first, the pull at A neutralises the second. To say that A supports B, would be an assertion like that of a person who should say that he had paid 11*l.* with 1*l.*, and should forget that he had borrowed 10*l.* elsewhere; and in the above system there is neither gain nor loss of force in any manner. When the weight B is lifted from the ground, and attached to the end of the lever, and when at the same moment the hand was applied at A, there is a pressure of eleven pounds applied to the earth at O. But all this pressure was first taken from the earth, ten pounds of it by the removal of the weight B, and the remaining pound by diminution of the weight of the person pulling; for a person who pulls downwards at a rope in such a manner as to supply the place of a pound weight at the end of the rope, lessens his weight by one pound.



In the preceding manner it may be shown that every machine in which A, the less, balances B, the greater, is a case of the following kind:—B is equivalent to certain forces, P, Q, R, &c., applied at various points of the system, and to C, equal and opposite to A. Imagine P, Q, R, &c. and C substituted for B, then P, Q, R, &c. are counterbalanced by the resistance of the parts of the machine, and C, and C only, is counterbalanced by A. It may also be shown that the whole pressure upon the earth is just what it would be if the machine were dismantled, and its parts, together with the weights, laid upon the ground.

Let us now consider the machine in motion. The paradox about power here is, that the smaller weight is made to lift the greater; for example, that a pressure, say of one pound, applied to the handle of a crane, lifts a weight say of twenty pounds. As long as no more precise mode of expression is employed, the paradox continues:—the smaller weight *does* lift the greater. To take the simplest case, suppose that the descent of a smaller weight causes the ascent of a greater, as in an inclined plane with a pulley. It is now obvious that before the larger weight B can rise through A C, the smaller weight A must fall through a length equal to B C. In any machine in which the hand, exerting a pressure of one pound, balances a weight of twenty pounds, the hand when put in motion to raise the weight, will move twenty times as fast as the weight. It is then one pound moved through twenty feet,



which is mechanically equivalent to twenty pounds moved through one foot, and the paradox disappears. It is usual to express this by saying that what is gained in power is lost in time; but instead of this axiom, which only indirectly expresses the truth, it is better to say that a less weight cannot cause the ascent of a greater through a given height, without descending through a height greater in the same proportion as that by which the greater weight exceeds the less. Perhaps the easiest mode of balancing the power applied and the work done is as follows:—Suppose one pound descending through four feet raises four pounds through one foot, we have then applied the descent of one pound through one foot four times, and produced the ascent of one pound through one foot four times. The only difference is, that in the applied power it is the same pound which moves over four different feet, while in the produced effect there are four different pounds moving over the same foot. The machine is nothing but an adaptation which enables the agent to effect the exchange just mentioned. And though the common notion that a machine gives power usually has reference to the substitution of a greater weight with less velocity for a smaller weight with greater velocity, yet it frequently happens that the apparent power is gained by the contrary exchange, as in the common grinding-wheel and in the lathe. Frequently also the beneficial effect arises from a reservoir of power which is given out in small quantities, as in a clock or watch, in which the exertion of raising a weight or coiling a spring is expended in minute quantities over one or more days.

Without entering further into the preceding principle (for which, in its mathematical bearing, see VIRTUAL VELOCITIES), we will now touch upon some additional circumstances connected with the use of a machine, still confining ourselves to simple exposition of these circumstances, and avoiding mathematical explanation. Suppose a crane by which a man, with a certain amount of labour, raises five hundredweight through a height of ten feet, working all the while as if he were raising half a hundredweight, by a simple pulley, from the deck of a vessel to the wharf. If this five hundredweight were divided into ten portions of half a hundredweight each, and if each of these portions had a rope fastened to it, it would matter nothing, the manner of working being equally convenient in both cases, whether he raised the whole at once by the crane, or the ten portions in succession by their several ropes. This supposes that there is no friction in the parts of the crane, and that its wheels can be moved without any exertion when unloaded. Neither of these is true, for the friction of the loaded machine is considerable, and even the unloaded machine costs some exertion to set it and keep it in motion. So far then the balance is in favour of raising the ten subdivisions of the five hundredweight in succession; and we now see what those persons mean who say that a machine is a loss of power. But if we introduce the beneficial effect produced by the machine, we see that the subdivision of the weight is avoided, and that the labour thereby saved may be thousands or even millions of times that caused by the friction of the machine and the necessity of moving its wheels, &c. A little attention to such reasoning as the preceding will prevent the reader, however unpractised in mechanical considerations, from being led away by accounts of perpetual motion [MOTION] and of machines which are to work without power applied.

The muscular power of men and animals, the force of wind, the fall of water, the expansive power of steam, &c, are real powers, the explanations of which lie in the secrets of the laws of life, gravitation, and chemistry. A machine is an adaptation of material elements to one or more purposes, the life of which is one or other of the powers just mentioned. But nothing is more common than, in describing the wonderful effects of power and adaptation united, to lay the wonder on the wrong part. Thus we can imagine a person describing the progress of mechanics in the last century, by saying that "lace is made by steam, and mines which would be covered with water but for the application of science, are cleared for the miners by machinery." In the first instance the steam-power is but subordinate; horses or a water-mill might supply its place without any diminution of the extraordinary part, which is the adaptation of machinery to the performance of that which required so many and varied motions of the fingers. In the second instance, common pumps, or successions of them, would do as well as the machinery employed, if hands enough could be found to work them: the wonder is the introduction of labour to any amount by the [help of steam. The vulgar notion is that steam, as steam, can adapt itself to anything, and that machinery, as machinery, can work.

POWER OF ATTORNEY. [LETTER OF ATTORNEY.]

POWER (Law). [USES.]

POZZUOLANO. A material used by the ancient Roman, and even by modern, hydraulic engineers for the purpose of preparing an artificial cement for works constructed in the sea. This material was originally obtained from the volcanic formations of the Bay of Puteoli, near Naples (from which circumstance the name itself is derived); but similar substances have been discovered in different parts of Italy and in other countries, and have been applied in the arts with equal success. In fact the pozzuolano is a dehydrized silicate of alumina, in which the silica exists in a state easily attackable by caustic alkalies, and is therefore capable at once of entering into a combination with the lime presented to it in the preparation of mortars, forming with it a double silicate of lime and alumina of an insoluble character; and substances of this description are very commonly met with in volcanic districts, wherein lava floods of a basaltic character have been poured out upon argillaceous beds. Thus in the environs of Rome itself the celebrated Catacombs were excavated in a large deposit of this argillaceous sand; in the island of Sardinia; in the south of France; in the north of Germany, near Andernach; and no doubt in countless other localities, the pozzuolano has been found under favourable economical conditions. The German material of this description is known in commerce under the name of *trass*, or *Dutch terras*.

Both the trass and the pozzuolano are used with the most favourable results when mixed with the purest and richest hydrates of lime; but the success of their application depends entirely upon the intimate nature of the mixture of the various ingredients, and upon the perfection of the hydration. These conditions can only be secured by the most perfect manipulation; and that again by the low price of manual labour; and it is on this account that the use of the natural cements, or of the artificial hydraulic cements, has been latterly introduced in most cases instead of that of the pozzuolano mortars which Smeaton and the earlier engineers so strongly recommended. But it is essential to remark (as was indeed before stated under MORTARS) that there are some conditions with respect to the state of the silicates of alumina entering into the composition of artificial cements, which are essential for their success; and, as far as our present means of analysis allow us to form an opinion on the subject, it would seem that these conditions are the most satisfactorily fulfilled when the combinations between the silica, the lime, and the alumina, are effected under great heat. This is actually the case with the Portland cements; and the very different results obtained by the mixture of the volcanically dehydrized silicates of alumina from those obtained by the mixture of underburnt brick earths, their chemical equivalents in nearly all respects, tend to confirm this opinion. It may be added that in Holland, Northern Germany, and in Italy, the pozzuolano class of materials is still used; but that in England they have so entirely been laid aside of late years as not easily to be obtained in the ordinary market.

Berthier gives the following analysis of the trass of Andernach and of the pozzuolano of Civita Vecchia:

Substances.	Trass.	Pozzuolano.
Silica	0·570	0·445
Alumina	0·120	0·150
Lime	0·026	0·088
Magnesia	0·010	0·047
Oxide of iron	0·050	0·120
Potash	0·070	0·014
Soda	0·010	0·040
Water and loss	0·144	0·096
Total	1·000	1·000

PRACTICE, a rule of arithmetic, appropriately so termed because it hardly contains any new principle, but depends for its application upon the memory and dexterity which the operator acquires from practice. Thus, in the following simple question, "How much do 40 yards cost at 18*d*. a yard," some arithmeticians (unpractised) might find it necessary to multiply 40 by 18 and divide the result by 12, for the number of shillings in the answer; but a practised arithmetician would immediately see that 18*d*. is a shilling and a half, so that 40*s*. must be allowed for the shilling, and 20*s*. for the half shilling, making altogether 60*s*. More complicated examples may require greater subdivision, but the method of proceeding has been completely described in the preceding. Suppose, for instance, it is required to find the price of 253¼ yards at 2*l*. 13*s*. 7¾*d*. a yard. The application of the rule of practice is as follows:—

At 1*l*. per yard 253¼ yards cost	£253	5	0	
			2	
2*l*. is 2 × 1*l*.	506	10	0	
10*s*. is ¼ of 1*l*.	126	12	6	
2*s*. is ⅕ of 10*s*.	25	6	6	
1*s*. is ½ of 2*s*.	12	13	3	
6*d*. is ½ of 1*s*.	6	6	7½	
1½*d*. is ¼ of 6*d*.	1	11	7¾	½
¼ is ⅙ of 1½*d*.		5	3¼	¼
At 2*l*. 13*s*. 7¾*d*. per yard 253¼ yards cost	679	5	9½	¾

The process hardly needs more description than is given on the left; the only difficulty is the division of the price into portions each of which is a simple aliquot part of one of the preceding, and this difficulty is to be overcome by practice. It is also to be noticed that easy verifications often occur: thus, in the last process but one, it can easily be verified that 253¼ farthings is 5*s*. 3¼*d*. ¼.

When both the factors which are to be multiplied contain complicated fractions, this rule can be easily applied by turning the money factor into pounds and decimals of a pound, as in INTEREST. Thus, suppose it is required to find the price of 22 tons 17 cwt. 1 qr. 19 lbs., at 13*l*. 16*s*. 4*d*. a ton, or 13·81667*l*. We have then

1 ton . . costs . .	£13·81667
	22
22 ton ,, ...	303·96674
10 cwt. is $\frac{1}{2}$ of 1 ton . . .	6·90833
5 cwt. is $\frac{1}{2}$ of 10 cwt. . . .	3·45417
2 cwt. is $\frac{1}{5}$ of 10 cwt. . . .	1·38167
1 qr. is $\frac{1}{8}$ of 2 cwt. . . .	·17271
14 lb. is $\frac{1}{2}$ of 1 qr. . . .	·08636
4 lb. is $\frac{1}{7}$ of 1 qr.	·02467
1 lb. is $\frac{1}{4}$ of 4 lb. . . .	·00617
22 ton 17 cwt. 1 qr. 19 lb. cost .	£316·00082

So that the proper answer is less than a farthing above 316*l*. The preceding process is much shorter than the application of the rule of three, and also than a kind of double rule of practice once in use, which is not given in modern works, and is not worth revival.

This method of practice is also a convenient way of reducing fractions of weights or measures to decimals. Thus, if 17 cwt. 1 qr. 19 lb. is to be reduced to a decimal fraction of a ton, we have

1 cwt. is ·05	of a ton.
17 cwt. is ·85	,,
1 qr. is $\frac{1}{4}$ of 1 cwt. or ·0125	,,
14 lb. is $\frac{1}{2}$ of 1 qr. or ·00625	,,
4 lb. is $\frac{1}{7}$ of 1 qr. or ·0017857	,,
1 lb. is $\frac{1}{4}$ of 4 lb. or ·0004464	,,
17 cwt. 1 qr. 19 lb. is ·8709821	of a ton.

PRÆFECTUS URBI (prefect or warden of the city), the title of a Roman magistrate, said to have been instituted by Romulus (Tacit., 'Annal.,' vi. 11) to supply the place of the kings in their absence from the city, within the walls of which he was for a time invested with kingly power, where he had the *imperium in urbe*. (Livy, i. 59.) He was appointed from among the senators. (Dionys., ii. 12.) During the time of the republic the præfectus urbi was appointed by the consuls, or by the senate (Dionys., viii. 64) when the consuls were obliged to be absent from the city. During the time of his office he exercised in the city the power of the consuls: he had the right to convoke the senate (Varro., 'Ap. Gell.,' xiv. 7, comp. with xv. 8) and to hold the comitia (Liv., i. 60). But in the course of time the prefect of the city was superseded by the prætor urbanus, on which the former magistrate became merely a shadow of what he had been, and was appointed while the consuls were absent from Rome for the purpose of celebrating the Feriæ Latinæ. This office, being of no importance, was often filled by young men, and Julius Cæsar even appointed several youths under age as prefects of the city. (Tacit., l. c., iv. 36; Dion Cass., xlix., p. 476.) This shadow of a magistrate seems to have continued to be appointed during the Feriæ Latinæ, even after Augustus had made a permanent præfectus urbi. (Suet., 'Nero,' 7.) Augustus invested this new prefect with considerable power, gave him the superintendence of public works, roads, aqueducts, the navigation of the river, and the corn to be distributed among the people. (Suet., 'Octav.,' 37; Tacit., l. c.; Dion Cass., lii., p. 547.) He was also invested with jurisdiction over slaves and turbulent citizens. He was thus something like a chief officer of the police; but his powers became gradually more and more extensive, so that almost all the powers formerly belonging to the office of prætor urbanus in the end were transferred to the præfectus urbi ('Dig.,' i., t. 12; 'De Off. Præf. Urbi,' comp. with Tacit., 'Annal.,' xiv. 41); and from the beginning of the 3rd century he not only exercised the inferior but also the criminal jurisdiction, and that not only in the city, but at the distance of one hundred miles from it. During the early period of the empire the prefect of the city seems always to have held his office for a number of years; but from the time of Valerian we find a new prefect almost every year. Respecting the titles by which he was addressed, see Brisson, 'De Form.,' p. 296. At the time when Constantinople was raised to the rank of second capital, it received a prefect of the city, who, like the prefect in the west, was the direct representative of the emperor, and next to him the first person in the city. The whole administration of the city, all its corporations and institutions, were under his superintendence; every month he made a report to the emperor of the transactions of the senate and people (Symmach., 'Epist.,' x. 44); in the assemblies of the senate he gave his vote before the consulars (Cassiod., 'Variar.,' vi. 4), and was the medium through which the emperors communicated with the city.

PRÆMUNI′RE (used for *præmonere*, "to forewarn," Co. Lit. 129 b) is the first word of an ancient writ by which a party was summoned before the sovereign to answer a charge of contempt against him. The commencement of the writ was as follows:—"Præmunire facias A. B. quod sit coram nobis," &c. The contempt consisted in the doing of some act in derogation of his allegiance; and in case of conviction, the judgment was, that the defendant should be thenceforth out of the king's protection, and his lands and tenements, goods and chattels, forfeited to the king, and his body should remain in prison at the king's pleasure. The word præmunire, as now used, has two meanings—one the writ itself, the other the offence to which the writ is applicable.

In late times it seems to have been considered that the offence was referrible only to attempts to introduce the papal authority into this kingdom; but it would appear that any attempt to introduce foreign jurisdiction or usurp upon the "kingly lawes of the crown" was equally within the penalties of a præmunire. Most of these attempts did relate to the papal jurisdiction, and the statute of præmunire (16 Rich. II., c. 5) relates only to such attempts. But the 27 Edw. III., c. 1, referred to by that Act, visits an analogous offence with the same penalty where one "shall draw any out of the realm in plea whereof the cognizance pertaineth to the king's courts, or whereof judgment is given in the king's courts, or which do sue in any other court to defeat or impeach the judgment given in the king's court, &c."

Numerous statutes have defined what shall be such a contempt as amounts to a præmunire. Most of the earlier are directed against *provisors*, as they were called, or persons who purchased from Rome provisions for holding abbeys or priories, &c., before those benefices were vacant (25 Edw. III., stat. 5, c. 22, stat. 6), or for exemption from obedience to their proper ordinary (2 Hen. IV., c. 3), or bulls for exemption from tithes (2 Hen. IV., c. 4), or those who held benefices in favour of aliens, &c. (3 Rich. II., c. 3; 7 Rich II., c. 12; 12 Rich. II., c. 15; 13 Rich. II., stat. 2, c. 2), or those who purchased (procured) bulls, sentences of excommunication, &c., against the king (16 Rich. II., c. 5). During the time of Henry VIII., several statutes applied the penalties of a præmunire to those who sued for or attempted to enforce any bull, &c., from Rome, or appealed there (23, c. 2; 24, c. 12; 25, cc. 19, 21; 28, c. 16), or refused to elect a bishop named by the king (25, c. 20). By 5 Eliz. c. 1, 13 c. 2, 27 c. 2, it was applied to those who refused to take the oath of supremacy, or defended the pope's jurisdiction, abetted publishers of bulls, &c., or sent relief to Jesuits beyond seas.

About this time the penalties of a præmunire ceased to be confined to the class of offences above referred to. The 13 Ch. II., s. 1, c. 1, made persons who advisedly assert that both or either house of parliament have a legislative authority without the king, and 4 Jac. I., c. 4, 1 W. & M., s. 1, c. 8, those who refused to take the oath of allegiance, guilty of a præmunire. By 7 & 8 Will. III., c. 4, serjeants, barristers, attorneys, &c., are subjected to the same penalties if they practise without taking the oath. By the 6 Anne, c. 7, a malicious or advised assertion that the then pretended Prince of Wales had any right to the throne, or that the king and parliament cannot make laws to limit the descent of the crown, amounts to the same offence. And 12 Geo. III., c. 11, attaches the same penalties to all such as willingly solemnise or assist, &c., at any forbidden marriage of the descendants of George II. The penalties of a præmunire have also been attached to persons guilty of offences of very different characters: to those who molested the possessors of abbey lands granted to Henry VIII. and Edward VI.; to brokers in any usurious contract, by 13 Eliz., c. 8; to those who obtained any stay of proceedings other than by arrest of judgment or writ of error in any suit for a monopoly, by 21 Jac. I., c. 3, s. 4; and to those who obtained an exclusive patent for the sole making or importation of gunpowder or arms, or hindered others from importing them, by 16 Ch. I., c. 21. By the Habeas Corpus Act, 31 Ch. II., c. 2, those who deprive or assist in depriving any subject of this realm of his liberty contrary to that Act, incur the penalties of præmunire; and by 6 Anne, c. 23, if the peers of Scotland convened to elect their representatives treat of any other matter, they are guilty of a præmunire. After the breaking of the South Sea bubble, those who thereafter engaged in such undertakings were, by 6 Geo. I., c. 18 (now repealed), made liable to the penalties of a præmunire.

The punishment of a præmunire has already been stated. After judgment, the defendant might formerly have been killed by any man. "But Queene Elizabeth and her parliament, liking not the extreme and inhumane rigor of the law in that point," made it unlawful to slay him. (5 Eliz., c. 1.) Still, being out of the protection of the law, he cannot sue in any action (Co. Lit., 129 b), and he forfeits all his goods and chattels, his lands and tenements in fee, and his life interest in lands in tail. (3 'Inst.,' 119, "Of Præmunire.") Prosecutions for this offence are now obsolete.

PRÆTOR, a word which apparently contains the same elements as the verb *præire*. The consuls were originally called prætors, but the name prætor was specially appropriated to a magistrate called the prætor urbanus, who was first appointed B.C. 365. He was called a colleague of the consuls, and was created with the same auspices. (Liv., vii. 1.) The prætor was at first only chosen from the patricians, as a kind of compensation to them for admitting the plebeians to fill one of the consulships. (Liv., vi. 42.) In the year B.C. 336 the first plebeian prætor was created.

The prætor, in his origin, seems to have been a kind of third consul. While the consuls were at the head of the armies in the field, the prætor exercised the consular power within the city, in the senate, and in the comitia. He also administered justice ("jus in urbe dicebat," Liv., vi. 42). On some occasions the prætor led the armies of the state. (Liv., vii. 23, &c.) Yet the imperium of the prætor was less than that of the consuls, to whom he owed obedience. There was also a distinction in his insignia of office, for the prætor had only six lictors, from which circumstance he is called by Polybius "the general with six lictors" (*ἡγεμὼν* or *στρατηγὸς ἑξαπέλεκυς*, and sometimes simply *ἑξαπέλεκυς*, &c.). It appears from Livy that the prætorship was originally given to a consul of the preceding year; and after the plebeians obtained admission to this magistracy, it was given alternately, at least for a time, to the patrician and plebeian consul of the preceding year. As the prætor was a kind of substitute for the consuls, there was nothing in the nature of the office which limited the number: and accordingly in B.C. 247, another prætor, called Prætor Peregrinus, was created, who administered justice in matters between citizens and foreigners, and in matters between foreigners only. It is conjectured that one prætor was a patrician and the other a plebeian, but this does not appear certain. If one of the prætors left the city to command the army, the other had the authority of both within the city; and when the military service required it, the imperium of a prætor was prolonged for another year by the senate or the comitia. When conquests were made beyond the limits of Italy, and foreign countries were reduced to the form of provinces, prætors were sent to govern them. Thus two new prætors were appointed for Sicily and Sardinia (B.C. 227), and subsequently two more when the two provinces of Spain were formed B.C. 197. The provinces of the prætors were determined annually by the senate, and distributed among them by lot. As the judicial labours of the prætors increased, they generally spent their year of office at Rome, and then took the charge of a province with the title of proprætor. Sylla increased the number of prætors to eight. The prætor urbanus had the highest rank, and was specially called prætor: the duties of his office required his constant attendance at Rome, and he could not leave the city for more than ten days at a time. He had the troublesome and expensive duty of superintending the Ludi Apollinares and giving gladiatorial shows to the people. Julius Cæsar increased the number of prætors to ten, then to twelve, fourteen, and sixteen; Augustus reduced the number to ten, then again raised it to sixteen, and finally fixed it at twelve. Under Tiberius there were sixteen. A permanent prætor for fidei commissa was subsequently appointed ('Dig.' i., tit. 2, s. 3), and another for matters between the Fiscus and private individuals; and a prætor was appointed by the emperor M. Antoninus (Capitol. 'M. Anton.,' c. 10) solely for matters relating to guardianship (tutela). The office continued in Rome with varying numbers and powers till the fall of the Western empire. At Constantinople it endured somewhat longer.

An office like the prætorship in some respects may be traced farther back than the first election of a prætor; and the vicarious duties of the office appear clearly in the functions of the ancient præfectus urbi [PRÆFECTUS URBI], whose office became of less importance on the appointment of the prætor urbanus. As late as the time of Cicero ('Ep. Fam.,' x. 12, xii. 28), we find the prætor performing the duties of the consuls in their absence.

Under the republic the prætor urbanus became the chief magistrate for the administration of justice, and in this respect his office was the most important in the state. He was one of the magistrates who had the Jus Edicendi (Gaius, i. 2), or of publishing edicta, which were the foundation of a body of law known under the names of Jus Honorarium or Prætorium. The prætor peregrinus had also the Jus Edicendi: and the edicta of these two prætors formed the largest body of this edictal law. The edicta of the prætor urbanus were published generally on entering on his office, and occasionally during its continuance. It is difficult to describe the edicta in exact terms, but they had reference only to civil actions, and their object was generally to provide for cases unprovided for by the existing laws, and mainly by introducing new kinds of actions (actiones utiles) when the actions of the old law (actiones directæ) did not apply, and fixing the mode of procedure. They often adapted a new form to an existing right, and they contrived by various legal fictions to accommodate the limited provisions of the old laws to the existing wants of society; but in all these proceedings we clearly discern a rectitude of intention and singleness of purpose as the characteristic of the edict. The prætor also interfered in a summary way by his Interdict, particularly in matters of possession [POSSESSION], in the case of a man who was of unsound mind and incompetent to manage his property, or a prodigal who was wasting his substance; in which cases the prætor appointed a curator, when the laws of the Twelve Tables had not provided for one. He also gave relief in cases of fraud whenever the law had made no provision ('Dig.' 4, tit. 3), and generally by the doli exceptio and the in integrum restitutio, in the case of minors, he set aside fraudulent transactions. (Savigny, 'Von dem Schutz der Minderjährigen,' Zeitschrift x. 261.) It is stated that the prætors would sometimes vary their edicta in the course of the year, till this was forbidden by a decree of the senate, and finally by a lex Cornelia (B.C. 67). This gave to the edict a character of greater stability. It seems that the edicta of his predecessors, though not absolutely binding on an actual prætor, were frequently adopted by him. Indeed we cannot conceive that the prætorium jus could have acquired that stability and consistency which it undoubtedly had acquired, even in the time of Cicero ('Leg.' i. 5), if the chief rules that were established by the prætors were not observed by their successors. The Roman jurists found ample matter for comment in the prætors' edicta, and a large part of their writings had for their object the exposition of the legal principles contained in them. Under the emperor Hadrian the edicta of the prætors were collected and arranged by Salvius Julianus, a distinguished jurist, under the name of Edictum Perpetuum, and from this time the progressive development of the Roman law by the prætors' edict ceased. The constitutions and rescripts of the emperors supplied the place of the edict; the importance of the functions of the prætors was greatly diminished; but they still presided in quæstiones, or judicial inquiries into crimes, or that class of offences which were the subject of judicia publica. Sometimes persons (quæsitores or quæstores) were appointed on special occasions to preside at such trials. After the number of prætors had been increased to six, the prætor urbanus and peregrinus exercised their usual jurisdiction, and the other four presided in quæstiones as to repetundæ, peculatus, majestas, and ambitus. These quæstiones were called perpetuæ (Cic., 'Brut.,' 102), apparently because the prætors exercised the functions of quæstores during the whole year of office, and not, as was the old practice, on the particular occasion only of their appointment as quæstores. Still extraordinary quæstores might be appointed. Sulla, by various leges, added to the number of quæstiones perpetuæ, and at the same time made two additional prætors, and when their criminal jurisdiction was withdrawn, their functions were little more than formal.

PRÆTORIANS was, in the time of the Roman republic, the name of a select cohort which attended the person of the prætor or commander of a Roman army. Sallust ('Catilina,' 60) says that Petreius, finding that Catilina and his followers defended themselves more stoutly than he expected, ordered, as a last expedient, the prætorian cohort to charge the insurgents, and this decided the fate of the battle. In the time of the triumvirate, Octavian and Antony greatly increased the number of the prætorians. Appianus ('Bell. Civ.') says that after the battle of Philippi they dismissed all those soldiers who had served their time, except 8000 men who requested to remain in the service, who were distributed in prætorian cohorts attached to the persons of the triumvirs. After the final overthrow of the republican party, Augustus formed the prætorians into nine cohorts, and Tiberius fixed their station in the capital as guards to his person. (Suetonius, 'August.,' 49.) They became in fact, under the emperors, what the regiments of guards or household troops are in the actual monarchies of Europe, a select and privileged body in the army. But besides their ordinary military duties, they had also the charge of state prisoners, and often acted as executioners. The prefect of the prætorium was the commander of the whole body of prætorians. They were all picked men, chosen from Old Latium, Umbria, Etruria, and the older Roman colonies, and they were proud of their origin. (Tacitus, 'Annal.,' iv. 5.) Under Vitellius the prætorian cohorts were increased to sixteen. (Tacitus, 'Hist.,' ii. 93.) In the frequent revolutions of the empire the prætorians acted a conspicuous part, and often determined the fate of an emperor, and the choice of another; as in later times the janissaries did with regard to the Turkish sultans. Diocletian reduced the number of the prætorians, and Constantine entirely disbanded them.

PRAGMATIC SANCTION. [CHARLES VI. OF GERMANY, and HOUSE OF HABSBURG in BIOG. DIV.; and TREATIES, CHRONOLOGICAL TABLE OF.]

PRAIRIES. [PLAINS.]

PRAYER, a term in theology, used to designate the intercourse passing between human minds and the divine. Language appears not to be necessary to complete the idea which the word represents, since we speak of mental prayer, which is thought directed heaven-wise in adoration or in entreaty without the sentiment of the mind being embodied in words or finding expression by the lips. But its far more common use is to express this kind of intercourse when the sentiment of the mind is embodied in language.

It is a derivative of the verb to *pray*, which signifies to ask for something, and the intercourse of which we have spoken is described by a word which etymologically describes only one part or section of the whole idea, inasmuch as in such intercourse the principal object will always be the supplication of those rich communications of good which God can bestow and man receive.

Prayer springs immediately out of the persuasion that man is not placed on this globe without a protecting and governing power over him, which power is conceived to belong to the One Great, Good, and Wise Being, who was the Creator at first of man himself, and of all the things by which he is surrounded, or which touch in any way his condition. Wherever this idea is fully formed, it seems that the mind must, occasionally at least, fall into the disposition to entreat that the Power, which can do so much for it, would be pleased to exert itself. Whether this government and this ability be vested in some one being, or be supposed to be distributed among many, either equal in power, or supreme and subordinate, the case is the same. Circumstances arise in which it seems that it would be impossible to withhold the mind from assuming the form of supplication and the lips from expressing the desires which have sprung in the mind. We accordingly find that prayer has existed from the earliest times when we find men raised into the rank of religious beings, and in any state of religious knowledge, however rude and mistaken the ideas may have been; in times of danger and calamity at least, men have thrown themselves prostrate before a superior power, and intreated its interposition.

Sometimes the prayer may be no more than a brief ejaculation; but if arising in the sincerity of the heart, it is not the less prayer, nor the less regarded by Him who is described in the Holy Scriptures as the God that heareth prayer.

But even in some of the earliest monuments of human thought and feeling we have prayer that has not been mere ejaculation, or even the mere expression of feeling excited by temporary emergencies: and there are come down to us various prayers used by good men in ancient times expressive of their desires, and at the same time showing how other topics may properly be introduced and mingled with supplication. There are prayers of men who had not the light of either of the divine dispensations, and there are wise directions concerning prayer in the writings of such men; but the Scriptures, both of the Old Testament and the New, contain many prayers, and many hints and observations respecting prayer, all of which are very instructive, and held in devout reverence by those who receive the persons whose words are there recorded as examples and authorities.

From these examples, and from the instructions incidentally given, Christian divines have deduced certain principles respecting prayer. They have in fact raised a kind of system of prayer: dividing and subdividing the several branches of it. Of these it will be sufficient to say that a prayer, or a body of words expressive of the intercourse, should contain (1) expressions of adoration and admiration of the Mighty Being who is the object of address, by which the mind is brought into a state of confidence that he can grant that which we entreat of him: (2) expressions of our own unworthiness to receive more blessings than he has already seen proper to bestow upon us; either on account of a general persuasion of demerit, or of some particular sin of which we have been guilty. This is thought to be in accordance with the actual state of every one who thus puts himself as it were more immediately in the awful presence of his governor and judge, and to be also salutary to the suppliant as keeping up a sense of proper humility, and a disposition to acquiesce in whatever may be the divine will. (3) Then comes the supplicatory part, in which general or particular blessings are besought, suitable either to the general condition of the person praying, or to the particular circumstances of the moment. (4) Intercession for others, the entreaty of the divine favour for the whole human race, and such blessings as particular classes of persons peculiarly need. This is thought necessary as cherishing the kind and charitable feelings, and leading each individual man to feel himself but as one of a great family of whom God is the common head and the common protector, and whose interests are not to be disregarded in attention to the wants and wishes of an individual member of it. (5) Lastly comes thanksgiving, a devout acknowledgment of past and present mercies, the good which God has given in his natural providence in general, or any special good which he may have granted. Such, according to Christian divines, ought to be the form into which men's thoughts cast themselves when they enter into communion with God: and the various prayers which are delivered in public by the ministers of religion in behalf of multitudes praying together, are for the most part constructed in this form, the differences arising (1) from the selection of different subsidiary topics under each, and (2) from the greater length in which each of these subjects is entered into, according to the feeling or the notions concerning prayer of the individual minister; and such also are the prayers for the most part in those collections of prayers many of which are printed for the use of persons, either in their private or family devotions, who find a difficulty in embodying in words the sentiment of the heart.

Liturgies are of the nature of printed collections of prayers. They are guides to the mode in which the prayers of many assembled in Christian congregations shall be offered. The Book of Common Prayer contains the Liturgy of the English Church as appointed by authority. The effect of liturgies in public worship is to restrain the manifestation of peculiarities in the notions of particular ministers respecting the nature and subjects of prayer: to keep out of the public assemblies of Christians extravagancy and enthusiasm; to bring the will of the community at large to bear on the wills of single ministers in respect of the devotional part of public worship; and to make known beforehand to the people what sentiments will be expressed, and in what form of words, in the service in which they are about to engage. [Liturgy.]

PREBEND, derived from the Latin word *præbeo* (to minister to, or yield), is an endowment in land, or pension in money given to a cathedral or conventual church *in præbendam*, that is, for a maintenance of a secular priest or regular canon, who was a prebendary as supported by the prebend. It is named from the land or other source whence the profits attached to it are derived.

A simple prebend was one which had only its revenue for its support; a prebend with dignity, one to which a jurisdiction was annexed; a prebendary holding the latter was styled a dignitary. Some prebends were donative, others in the gift of laymen, who, in case of vacancy, must have presented the future prebendary to the bishop; on this the bishop instituted him, and the dean and chapter then inducted and placed him in a stall in the church. If a bishop were the patron, he collated. At Westminster the king collated by patent, by virtue of which the prebendary took possession without institution or induction. A mandamus lies to compel an election to fill a vacancy. During a vacancy the profits belonging to a prebendary as sole corporator went to his successor; those which he held as member of the corporation aggregate were divided among the dean and chapter. A prebend being a benefice without cure of souls, was not formerly incompatible to be held with a parochial benefice, but one prebendary could not possess two prebends in the same church, though he might hold a second in any other. But now, by 1 & 2 Vic. c. 106, no spiritual person holding more benefices with cure of souls than one shall hold any cathedral preferment; or, holding any cathedral preferment and also any benefice with cure of souls, shall hold any other cathedral preferment; or, holding any preferment in any cathedral or collegiate church, shall hold any preferment in any other. (Comyns's 'Digest,' tit. 'Eccl. Persons,' iii. 600; Burns, 'E. L.,' 88, 90; Rogers, 'On Ecclesiastical Law, tit. 'Dean and Chapter.' [Dean.]

By the 3 & 4 Vic., c. 113, founded on the Report of Commissioners appointed to consider the state of the church with reference to its revenues, very important changes were made relative to cathedral preferment. The statute does not affect existing interests. Its provisions, in general terms, are as follows:—Henceforth all the members of chapters are to be styled canons. Provision is made for the suppression of many existing prebends, the creation of one additional for St. Paul's, and ultimately all cathedral and collegiate churches as to number of canons, are to be placed upon the following footing:—Canterbury, Durham, Ely and Westminster 6 each; Winchester and Exeter 5; Bristol, Carlisle, Chester, Chichester, Gloucester, Hereford, Litchfield, Lincoln, Manchester, Norwich, St. Paul's, London, Peterborough, Ripon, Rochester, Salisbury, Wells, Windsor, Worcester, and York, 4 each; and St. David's and Llandaff 2 each.

All bishops are authorised to confer honorary canonries, without emolument, to the number of twenty-four, in each cathedral church.

No canon is, by virtue of his canonry, for the future to possess any separate estate or income, all of which are to vest in the Ecclesiastical Commissioners appointed by 6 & 7 Wm. IV. c. 77. The profits of the suspended canonries are to be paid to the commissioners, in whom their estates, as well as those of non-residentiary prebendaries, &c., are to vest. The annual incomes are also fixed by this statute. The separate patronage of members of chapters is to be vested in the respective bishops. Provisions are made as to the exercise of the patronage of chapters. The minor canons are to be appointed by the chapter.

PREBENDARY ('Prebendarius'), one who has a prebend [Prebend], a canon endowed with land or an advowson or tithe. In right of his prebend, he possessed an estate. He was bound by canon 42 to residence four score and ten days during each year. The time fixed by 3 & 4 Vict. c. 3, is three months. The whole body attached to each cathedral or collegiate church forms, with the dean, a corporation aggregate, called the dean and chapter. Each prebendary, having a distinct estate, is, by virtue of that, a sole corporator, as well as member of the corporation aggregate. The office of the dean and chapter is to consent to the grants, leases, &c., of the bishop. Anciently they formed his council, as they still do nominally. On his death they certify the king of it in chancery, upon which a congé d'elire is issued. During the vacancy, they govern the diocese and guard the spiritualities of it, unless where the archbishop has that right by prescription. Prebendaries were bound by canon 43 to preach in their churches, and in other churches in the diocese, especially those whence their profits proceeded, or to substitute other preachers approved by the bishop. A prebendary could not make a grant, &c., until after installation and induction. [Dean; Chapter.] (*Termes de la Loy*, tit. 'Prebend,' 'Chapter;' *Com. Dig.*, tit. 'Ecclesiastical Persons.')

PRECEDENCE, one of the artificial distinctions among men living in a state of political society. In all countries the great mass of mankind will be of one level, no individual possessing political privileges which do not belong to the rest, except as pertaining to some particular employment in the various ordinary businesses of life in which each individual is engaged. But these give no precedence of one before another; all move on abreast. But above these are certain persons, such as the members of the liberal professions, persons who hold or have held offices in the state, peers, who take precedence of the rest, and who are allowed to do so, if not by any law absolutely promulgated, yet by the constant usages of society. And again, the individuals, who may form perhaps the thousandth part of the whole community, who possess this privilege of precedence, have the precedence amongst each other regulated according to usage, or, in other words, by the precedents established in records of former arrangements. The subject is one to which a good deal of attention has been paid, and it is now only as an incident to the creation of new courts or officers, or in singular positions of the royal family, that difficulties arise. The members of the College of Arms, who are the council of the earl-marshal of England, are usually referred to in questions of precedency; and to them is assigned the arrangement of public processions, as at royal marriages, funerals, coronations, and the like, when it is that questions of this kind come to be considered.

Tables of precedency may be seen in many books, and especially in those called Peerages.

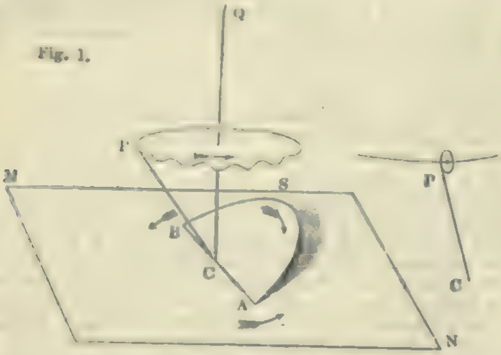
Sometimes the question arises among ambassadors who shall enter a room or depart before another, and great tenacity has at times been manifested in supporting the claims to rank of the state or kingdom represented. In the 'Philoxenis' of Sir John Finet there are some almost ridiculous instances of the struggles made for precedence by ambassadors of the state of Venice in the reign of James I.

PRECESSION AND NUTATION, the abbreviated way of expressing the precession of the equinoxes and the nutation of the earth's axis.

These phenomena should always be considered in connection wit the rotation of the earth, of which they really form a part; that is to say, diurnal rotation, precession, and nutation are the motions of the earth about its centre, independently of the motion of that centre along its orbit round the sun. It will assist our comprehension of the subject to suppose the earth's centre a fixed point, the relative motions of the heavenly bodies being adjusted accordingly. [MOTION.]

The rotation of the earth round its axis is visible from hour to hour by the change of place in the stars: the precession and nutation are motions of too slow a nature to be rendered visible, and indeed could hardly be made so unless the ecliptic and equator were visible circles. If such were the case, and if the motions were large enough, the equinoxes, or intersections of the equator and ecliptic, would appear to change place, the equator moving slowly round the ecliptic with a retrograde motion, that is, contrary to the annual course of the sun. The equinoxes would appear to move with a variable motion, sometimes a little faster and sometimes a little slower than the mean motion. At the same time the equator would appear to swing backwards and forwards to and from the ecliptic, turning upon the equinoxes as pivots. Of these motions the average motion of the equinoxes upon the ecliptic is the precession; the alternate acceleration and retardation is one part of the nutation; and the alternate increase and diminution of the angle contained between the two is the other part. It is however common to call the acceleration and retardation of the motion of the equinoxes by the name of the equation of the equinoxes, and to reserve the name of nutation for the motion of the pole which corresponds to it.

Fig. 1.



Let C be the centre of the earth, C P half its axis, P the north pole, and A S B half of the equator. Let M N be part of the plane of the ecliptic, and C Q a line perpendicular to it, pointing therefore to the pole of the ecliptic in the heavens: and let the direction of the diurnal rotation be that of the arrow marked on the equator. If then P were carried uniformly round a circle perpendicular to C Q, so that C P should describe a conical surface, the equinoxes B and A would be carried round in a direction contrary to that of the diurnal motion, and with them the equator B S A, the angle which the equator makes with the ecliptic remaining unaltered. This motion of B and A is the precession. But suppose that instead of P being placed on the circle, it is placed on the circumference of a small oval, which has its centre on the circle. While the centre of the oval moves forward on the circle with the motion of precession, let the pole P move round the oval with a motion much slower than that of the precession. It will then trace out in space an undulating curve, as shown in the principal diagram, and the effect will be an alternate retardation and acceleration of the motion of the equinoxes along the plane of the ecliptic, together with a vibration of the plane of the equator to and from the ecliptic; which are the motions described as constituting the nutation.

The preceding is a description of the effect of any one of the heavenly bodies, theoretically speaking, upon the axis of the earth. The whole precession and nutation is the united effect of the sun, moon, and planets. The effect of the planets however is insensible, except in a slight annual alteration of the plane of the ecliptic, which is mixed up with the precession, and makes it appear a very little smaller than it would be if the system of the sun, moon, and earth were undisturbed by the planetary attraction. The general reader need only attend to the main phenomenon, namely, that the equinox (the point of the heavens at which the sun is at the commencement of spring) moves slowly * backwards along the ecliptic, at the rate of 50¼ seconds per annum, or about 14° in one thousand years. This rate of motion is subject to a very slow increase, which is not perhaps sufficiently well determined to make it worth while to compute exactly the time in which the equinox describes the whole heavens, a period of between twenty-five and twenty-six thousand years.

A good notion of precession may be got from observing the spinning of a top. As long as the axis of the top is not vertical, this axis itself revolves, but much more slowly than the top revolves round its axis. Let the top be supposed to remain with its axis at one angle to the vertical, except only a slight balancing motion to and from the vertical, and let the conical motion of the axis be slightly accelerated and retarded: this will give a complete notion of the phenomena of precession and nutation.

Before proceeding to the mathematical and physical description of these phenomena, we shall show the manner in which they may have an historical and chronological importance. Let the reader take a globe or a map of the stars, he will see that the ecliptic crosses the equator under the tail of one of the Fishes, so that the vernal equinox is nearly in a line with the stars α Andromedæ and γ Pegasi (Alpherat and Algenib). These stars then are invisible at the beginning of the spring, being in the region of the heavens nearest to the sun. Let from twelve to thirteen thousand years elapse, and the slow precessional motion of the equinoctial points will reverse the positions of the equinoxes, so that the above-named stars will be near the meridian at midnight at the commencement of spring, as the stars in the head of Virgo are now. An Aratus of our day would celebrate the brightness of Virgo in the nights of spring, while one of thirteen thousand years hence must choose Pisces for that purpose. The seasons of the year at which different stars begin to be distant enough from the sun to shine brightly is undergoing a gradual alteration. Hesiod, for instance, says that in his time and country Arcturus rose at sunset in sixty days after the winter solstice; Newton calculated that this took place about B.C. 870, which is one of his reasons for supposing that the poet was alive about that time. The phenomenon however is itself rather vague, and Hesiod may be supposed not very exact in his description. It is generally considered that Newton attached too much importance to such data in settling his system of chronology.

About two thousand years ago the equinox was twenty-eight degrees more advanced among the signs, and was near the beginning of the constellation Aries. It was about this time that the precession of the equinoxes was discovered by Hipparchus [ASTRONOMY; HIPPARCHUS, in BIOG. DIV.], and since that time the vernal equinox has preserved the title which it properly held at the time when its motion was discovered, namely, the first point of Aries. Certain astronomical fictitious constellations have been made to move with the equinox, at least until lately; counting from the equinox, the first thirty degrees of the ecliptic have been always called Aries, the second thirty Taurus, and so on. Thus when an astronomer of the middle ages asserts the longitude of a star to be ♎ 18° 22′, he means that it is in 18° 22′ of the astronomical Libra, a constellation supposed to begin at 6 × 30° or 180° distance from the vernal equinox. An astronomer of our day would say the star's longitude was 198° 22′.

Taking the beginning of the year 1750 as the starting point (as is generally done since the publication of the 'Mécanique Celeste'), and calling t the number of years elapsed, the whole motion of the equinoxes from precession, including the effect of the planetary action on the ecliptic, is

$$50''{\cdot}176068\,t + 0''{\cdot}0001221483\,t^2,$$

while the precession in one year is

$$50''{\cdot}176068 + 0''{\cdot}0002442966\,t.$$

M. Bessel substitutes 50″·21129 for 50″·176068.

The obliquity of the ecliptic, assumed at 23° 28′ 18″ in 1750, is

$$23^\circ\,28'\,18'' - 0''{\cdot}48368\,t - 0''{\cdot}00000272295\,t^2;$$

its yearly diminution, arising from the planetary action, independently of nutation, being

$$0''{\cdot}48368 + 0''{\cdot}0000054459\,t.$$

M. Bessel takes 23° 28′ 17″·68 for the obliquity in 1750, and uses 0″·457 instead of 0″·48368.

The nutation affects both the place of the equinoxes and the obliquity of the ecliptic. Let $\Delta\lambda$ denote the nutation in longitude, $\Delta\epsilon$ the effect upon the obliquity of the ecliptic. Then, according to Professor Peters ('Numerus Constans Nutationis'),

$$\Delta\lambda = -17''{\cdot}2491 \sin ☊ + 0''{\cdot}2073 \sin 2☊ - 0''{\cdot}2041 \sin 2☾ + 0''{\cdot}0677 \sin(☾ - \pi') - 1''{\cdot}2692 \sin 2☉ + 0''{\cdot}1277 \sin(☉ - \pi) - 0''{\cdot}0213 \sin(☉ + \pi).$$

$$\Delta\epsilon = +9''{\cdot}2235 \cos ☊ - 0''{\cdot}0897 \cos 2☊ + 0''{\cdot}0886 \cos 2☾ + 0''{\cdot}5508 \times \cos 2☉ + 0''{\cdot}0093 \cos(☉ + \pi),$$

in which expressions ☊ denotes the longitude of the moon's ascending node, ☾ the longitude of the moon, ☉ the longitude of the sun, π, the longitude of the perihelion of the earth's orbit, and π', the longitude of the moon's perigee.

It thus appears that by far the largest part of the effect of the nutation arises from the moon, and depends not upon the place of the planet, but upon that of its node. This node [MOON] performs a complete regressive revolution in about eighteen years and a half, in which time the main effect of nutation goes through all its changes. Bradley, the discoverer of the nutation, found out and assigned the law of its largest term; the remaining ones are due to the theory of gravitation. It took him twenty years of observation, somewhat more than the whole period of the change, to detect the law of the anomaly whose existence he became sensible of immediately after his discovery of aberration had cleared away the largest part of the then unexplained motions of the stars. The discovery was completed and published at

---

* It will perhaps be more intelligible to imagine all the stars moving slowly forwards in parallels to the ecliptic, the equinox remaining unchanged.

the end of 1747. In 1749 appeared the 'Recherches sur la Precession,' &c. of D'Alembert, in which the phenomenon was shown to be the necessary consequence of the moon's attraction upon the earth. Newton had already, in the 'Principia,' given the general explanation of the subject, and had even foretold, without assigning magnitudes, the existence of those terms of nutation which depend upon twice the true longitudes of the sun and moon; but the most important terms, those depending on the moon's node, appear to have been altogether unsuspected by him.

We now come to such a physical explanation of the cause of precession and nutation as can be given without mathematical analysis. On looking at the motion of the equator arising from precession and nutation, we see that it precisely resembles in character some of the alterations which take place in a planet's orbit, the precession answering to the regression of the nodes, the equation of the equinoxes to the variation of that regression, and the remaining part of the nutation, or the variation of the obliquity, to the variation of the inclination to the ecliptic. It was soon seen by Newton, that on the supposition of the mutual attraction of all the particles of matter, the action of the heavenly bodies on the protuberant parts of the earth must produce exactly that sort of effect on the motion of the equator which the disturbing force of the sun, for instance, produces on the moon. He thus explains, firstly, the precession; secondly, that part of the nutation of the inclination which depends upon twice the longitude of the disturbing body. This explanation (prop. 66, corollaries 18-22) is substantially as follows:—

If a sphere in rotation be attracted by another body, the axis of rotation must remain unaltered: for since a plane drawn through any attracting point and the centre of the attracted sphere cuts the sphere into two perfectly similar halves, there is no effect upon the rotation (or tendency to an effect) arising from the attraction upon one half of the sphere which is not destroyed by the tendency to the exactly opposite effect arising from the attraction upon the other half. If then the earth were a perfect sphere, whatever motion of translation the whole sphere might receive, the axis would always remain parallel to its first position, and there would be neither precession nor nutation. Again, let the earth be a solid of revolution, protuberant for example at the equator, as is the case, and let an attracting point be situated in the plane of the equator; the symmetry just alluded to still exists, and the result is the same. But if an attracting point be not situated in the plane of the equator, the plane passing through the attracting point and the centre divides the spheroid into parts which, though equal, are no longer similarly situated with respect to the attracting point. The alteration of the axis which would take place if one half only were attracted, is no longer counterbalanced by the attraction on the other half: the direction of the axis is therefore continually changed.

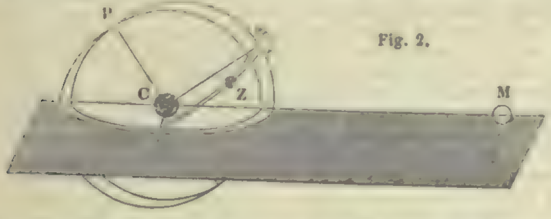


Fig. 2.

To get a specific idea of the nature of the change, first suppose the spherical part of the earth only to exist, the protuberance being removed; and the solidity of the sphere still remaining, let all its matter be supposed to be removed to the centre at C (*Fig.* 2). The diagram shows the spheroid of the earth, distinguishing the inscribed sphere from the protuberant part; the solidity of both parts is supposed to remain, but the matter of the internal sphere is removed to C, that of the protuberant part is not yet introduced: M is the attracting body, and the plane of its orbit is given, while the directions of the earth's rotation and of M's orbital motion are denoted by arrows. At present M produces no effect on the rotation; now let a small mass of matter be affixed to the equator at Z, which will therefore move round the mass C in and with the equator. The consequence will be [Gravitation], that the node of this orbit (the equinox A) will regress, or move in the direction opposite to that of the arrows, while the inclination of the orbit will alternately increase and diminish, being greatest when the line CM passes through one of the equinoxes. If we put such satellites all round the equator, the effect will not be altered in quality, but increased in magnitude; and if we fill up all the protuberant part of the spheroid, the effect will still be of the same sort, though further increased in magnitude. The effect of the parts of the protuberance nearer to the pole is, for a given mass, less than that of the parts near the equator. Finally, if we restore the mass of the internal sphere to its proper place, the effect will be less than before; for since no motion of the protuberant part can take place without one of the whole sphere, and since rotation is more difficult to produce, the greater the distance of the masses moved from the axis, the distribution of the mass at C over all parts of the sphere will render M less efficient in the alteration of the direction of the axis. Thus it appears that the phenomena of precession and nutation *may* arise from the consideration of the protuberant part of the spheroid as a fixed satellite to the internal part; but the proof that the precession and nutation *do* so arise consists in taking a strict mathematical process, investigating the precession and nutation in quantity as well as quality, and showing that the results agree with those of observation.

But, as before noticed, the largest part of the nutation depends, not on the place of the moon in its orbit, but on the position of the orbit, that is, on the node of the orbit. Supposing the moon's orbit circular, imagine the mass of the moon to be distributed in a ring all round its orbit. If this ring were simply to revolve in its own plane, the precession and nutation produced by it in the earth, though materially altered in quantity, would be of the same sort as before, and in both cases very small. But suppose the ring to shift its position, as does the moon's orbit, its nodes slowly regressing at the rate of a revolution in eighteen years. This shifting of the position of the ring will of course produce an alteration in the phenomena, and the substitution of the moon revolving in a shifting orbit in place of this ring must now be made. That the effect of the change of the orbit should be greater than that of the planet itself in a fixed orbit ought not to be surprising, since there is no *à priori* reason why it should be either greater or less.

Throughout the solar system there is no action of one planet upon a second, without a corresponding action of the second upon the first. The protuberance of the earth, by which the planets produce precession and nutation, attracts those planets, and slightly varies their motion. In the case of the moon, sensible irregularities, both in longitude and latitude, amounting at the maximum to about 7" in each, were found by Mayer, before Laplace showed them to be the consequences of the earth's protuberance. These inequalities may be made the means of calculating the amount of that protuberance, or, as it is technically called, the ellipticity of the earth: and it is a fact not a little remarkable, that the amount of this ellipticity, as calculated from its effect upon the moon's longitude, agrees with the same, as calculated from its latitude, better than actual measurements of the earth generally agree with one another, while both agree very nearly with the best of the latter. This sort of result had been anticipated as to quality by Newton, who showed that the motion of the equinoxes, being retrograde, proves the earth to be protuberant at the *equator*, and that if it had been protuberant at the *poles* (as many then thought was the case), the precession would have been in the contrary direction.

PRECIPITATE. A name given in chemistry to any comparatively insoluble solid or liquid matter separated from a liquid by chemical action. It is also, though more rarely, applied to solid or liquid matter deposited from a gas; thus snow and rain may be termed precipitates from the atmosphere.

PREDESTINATION. [Election; Free-Will; and Calvin, in Biog. Div.]

PREDICABLES. The term predicable (*κατηγορικόν, prædicabile*) is applied in logic to general names, considered as capable of being the predicates of propositions. (On Predication, see Organon.] The classes of predicables usually recognised by logicians are five, namely, 1, Genus; 2, Species; 3, Differentia; 4, Proprium; 5, Accidens, which Latin names are translated from the Greek, 1, *γένος*; 2, *εἶδος*; 3, *διαφορά*; 4, *ἴδιον*; 5, *συμβεβηκός*.

The five-fold classification of the predicables does not occur in Aristotle's 'Organon,' nor in any other of his extant writings; and it probably did not occur in any of his lost writings. The word *γένος* is often used by Aristotle to signify a class: and the word *εἶδος* in the sense of a logical species. The word *συμβεβηκὸς* (or *κατὰ συμβεβηκὸς*) is often used by Aristotle to signify that which is contingent or accidental, in opposition to that which is necessary (*ἀναγκαῖον*).

The earliest work in which the received classification of the predicables occurs, is an Introduction to Aristotle's Categories, written by Porphyry of Tyre, the well-known heathen philosopher of the 3rd century (born 233 A.D.) and the author of other extant works. (Printed in Bekker's Aristotle, vol. iv., p. 1–6). Porphyry states, at the outset of this treatise, that a knowledge of the five predicables is necessary for the proper explanation of Aristotle's work on the categories; and he therefore addresses to a certain Chrysaorius a popular account of them, derived from the ancient philosophers, especially the Peripatetics. The five predicables (*αἱ πέντε φωναί*, as they were originally styled) are not however mentioned in Aristotle's work on the categories, as is incorrectly stated in Hermeias, ib., p. 10, b. 14; and it is probable that the "ancient philosophers" alluded to by Porphyry were of considerably later date than Aristotle. An abridgment of Porphyry's treatise on the predicables, by Michael Psellus, of Constantinople, who lived in the 11th century, has also been preserved; and it is reprinted in the beginning of the small Oxford edition of 'Excerpts from Aristotle's Organon' (Clarendon press, 1802).

From this treatise of Porphyry the classification and explanation of the predicables have passed into the various treatises of the Aristotelian logic, and have been repeated in them with some variations and developments, but with little substantial change up to the present day (Whately's 'Logic,' part i.)

The explanation of the predicables which is usually given in treatises on logic is somewhat infected with realism; that is to say, it implies that there is something in nature, besides individual things, corresponding with general notions. On this point see Mansel's 'Aldrich' (§ 5 and Appendix A). Or if not, the least that can be said is that these definitions have an extralogical relation to metaphysics.

The name of any proposed class may be called the *species*; for example, man.

The name of any class including this class is called a *genus*, with reference to the species; for example, animal, with reference to man.

Differentia is the name of any attribute which belongs universally to the species, and to it alone *in the genus*. For example, the power of ameliorating his condition in successive generations, and the power of using language, as belonging to man. A logical *definition* is composed of the *genus* and the *differentia*; thus, according to the explanation of differentia which has been just given, man would be defined logically by saying that he is "an animal which possesses the power of using language."

Proprium is the name of any attribute which belongs to the species, and to it alone. For example the power of speech, as belonging to man.

Accidens is the name of any attribute which may or may not belong to any individual of the species. For example, the colour of the skin in man.

We might fill columns with the views which have been taken of the *proprium* and *accidens*.

We now proceed to consider the predicables, or substitutes for the predicables, which enter into a purely logical system in which contrary terms are admitted. [LOGIC, col. 354.] The predicables which Aristotle really uses are *genus, species*, and *accident*: and as names of class, the genus and species have *terminal precision*. The genus is more than the species; the species less than the genus. The *accident*, which belongs to some but not to all, has a definition which made Aristotle confess that the species is an accident of the genus; distinguished of course from some other accidents by having no exience; that is, by not being the accident of anything external to the genus. According to Aristotle's use of the words genus and species, a species as large as the genus does not exist. We have allowed the term *species* to be used where the genus has but one species: and we must accordingly use other terms. Again, the really metaphysical character of the old terms can only be represented in our system by referring the predicables to the logico-*metaphysical* side of logic. Consequently, our predicables must be the metaphysical notions attached to the relations of terminal precision. [LOGIC, col. 350.] Though obliged to abandon the words *genus* and *species*, we find use for the adjectives *generic* and *specific*, which have parted from their substantives in common language quite enough to justify the use we make of them.

Let a predicated attribute, considered with reference to a class or to another attribute, be *inherent* when the predicate always belongs to the subject; *excludent*, when it never belongs to the subject; *accident* and *non-accident*, when it belongs to part of the subject, and not to the rest. When contrary terms are introduced, the definition of *accident* is also that of *non-accident*: either is the other, by mere force of definition. The *inherent*, the *excludent*, and the *accident* (*non-accident*), are then the three predicables. Each of these predicables may be either *universal, generic*, or *specific*.

A predicable is *universal*, with reference to the term of which it is predicated, when it belongs, in the same sense, to both the classes into which the term divides the *universe*. Thus in the universe *animal*, divided into *man* and *brute*, *life* is a universal *inherent*, inherent both of man and brute: *mineral* is a universal excludent, both of man and brute; *strength* is a universal accident and non-accident, belonging to some both of men and brutes, and not to the rest. The universal predicables create no distinction, and are therefore of little or no logical force.

A predicable is *generic* when its quantity of application is augmented by taking in the additional extent of some larger genus, in which the term predicated of is a species: *specific*, when this is not the case. Thus, *lawyer* is a *specific accident* of man; *accident*, some are and some not; *specific*, any larger genus of animal which contains man has no *lawyer* in the additional extent. For these reasons it is also a *generic* non-accident. The following table will now be easily collected; and the reader of the article LOGIC will see that, just as the words *sub-identical, superidentical*, &c., might be dispensed with, since *deficient species, extent genus*, &c., might supply their places, so the extended system of predicables might be replaced in terminology by one derived from compounding the metaphysical relations of terminal ambiguity. The symbols are here read forwards :—

)o)	Inessential Dependent . .	Specific Accident Generic Non-accident
| |	Dependent Essential . . .	Specific Inherent
(o(	Independent Essential . .	Generic Inherent
)o(	Inalternative Repugnant . .	Generic Excludent
| · |	Repugnant Alternative . .	Specific Excludent
(o)	Irrepugnant Alternative . .	Generic Accident Specific Non-accident

The old predicables, taken together, do not constitute a *logical* list of predicates. Their companions, the CATEGORIES, are now almost universally declared to be metaphysical, not logical. Sir W. Hamilton, in the recently published 'Lectures[*] on Logic,' does not mention the word *predicable*: at least it is not in the index, and we cannot find it in the proper places of the work.

PREDICAMENTS. The Latin term for the CATEGORIES.

PREDICATE. [ORGANON.]

PREFIX. [LANGUAGE.]

PRELATE (etymologically from *præ* and *latus*), a person *preferred* or advanced before another; but it is confined to a particular species of preferment or advancement, namely, that amongst the clergy, and it is applied to those only among them who have attained the very highest dignity, that of bishop or archbishop, to which we may add patriarch, in such churches as have an officer so denominated. The word prelate has, however, in ancient times been applied to simple priests members of the clerical body in general.

PRELUDE (*Præludium*, a preamble), a brief introduction to a piece of (most commonly) pianoforte music; a few chords or a flourish, to prepare the hand of the player, and draw the attention of the auditors to what is to follow. A prelude is, or is supposed to be, an extemporaneous effusion, and as such is no bad test of the musical knowledge of the performer.

PREMISES. [ORGANON.]

PREMIUM (in the sense in which it is used in the article BOUNTY) is a reward given out of the public revenue to encourage manufactures or other branches of industry; but prizes given by agricultural and other societies are in reality the same thing as premiums. Premiums encourage and reward competition; but when it is proposed to foster any new art by liberal premiums, there is less certainty of an interest thus sustained establishing itself upon the only natural foundation—that which arises from the encouragement of the public; and premiums then fall under the same objections as bounties. These objections are inseparable from a system of bounties, but the judicious distribution of premiums may occasionally be attended with advantage. Adam Smith says of premiums that, "by encouraging extraordinary dexterity and ingenuity, they serve to keep up the emulation of the workmen actually employed in those respective occupations, and are not considerable enough to turn towards any one of them a greater share of the capital of the country than what would go to it of its own accord." A patent is a sort of premium for the encouragement of useful inventions; but the giving of money to support an otherwise unprofitable manufacture must be injurious to the community.

PREMONSTRATENSIAN ORDER. [AUGUSTINE, CANONS OF THE ORDER OF.]

PREPOSITIONS are certain words which express a relation between different things. All words may be divided into notional and relational. [NOTION, NOTIONAL.] Notional words are those which express notions, and which are objects of the understanding. Relational words are those which merely express a relation between the different things which are expressed by notional words. Thus, in "he went *to* town," "he walked *with* his friend," the words *to* and *with* are relational words; that is, they connect the notions of "he went" and "he walked" respectively with the notions of "town" and "friend."

Prepositions are so called because they are *preposed* or prefixed to the words with which they are connected; but the name is an unfortunate one, since they are sometimes *postponed* or placed after such words, as in *wherewith, wherein, wherefrom, thereby*, &c. In languages like our own, which have hardly any inflections, the relation which one thing bears to another can only be expressed by means of prepositions; but in languages which possess inflections, like the Latin and Greek, the same relation may frequently be expressed by means of cases, which are in fact prepositions placed at the end of nouns. Thus, in the expression "the son *of* the king," we express the relation between "son" and "king" by the preposition "of"; while in Latin the same relation is expressed by *is* placed after the Latin word for king, *filius reg-is*. But as the meaning of those case-endings was not always definite enough, it became customary to mark the relation more precisely by prefixing certain words, as in our own language. The case endings however were not dropped; so that in such expressions as *ad urb-em, cum reg-e, pro reg-e*, the noun may be said to have two words to mark relation, one placed before and the other after it.

The number of prepositions differs, as might be expected, in different languages. The Greek grammarians admit only eighteen, the Latin about fifty. In English, the following words are usually considered as prepositions:—Above; about; after; against; among, amongst; amid, amidst; around, round; at; between, betwixt; beyond; before; behind; beneath; below; beside; by; down; for; from; in, into; near, nigh; of; off; over; on, upon; since; through, throughout; till, until; to, unto; toward, towards; under, underneath; up; with; within; without.

---

[*] Those lectures were published a few days after our article on LOGIC: edited by Mr. Mansel and Mr. Veitch. They fully confirm, to our minds, all that we said both for and against Sir W. Hamilton. Our idea of his power over everything but quantity is enhanced: and so is our opinion of his utter incapacity in all that is mathematical in notion. The editors have faithfully preserved to us the means of judging of this difference. We hold these lectures to be the greatest of Hamilton's works: they were substantially written when he was first appointed to his chair; and so much do they preserve their primitive character, that, though read year after year for twenty years, the lecturer always read, in lecture 3, the following words: "I would interpolate some observations which I ought in my last lecture to have made . . . ." There is, accordingly, a freshness about the style which is truly pleasing; and the worst we have to say about the non-quantitative portions is, that Hamilton has frequently supplied, by translation from Krug and Esser, what he would have done much better with his own pen. His own system does not form a part of the lectures; and the scraps which the editors have been able to find do not add anything material to what was known of it before.

Besides these prepositions, there are in English, Latin, Greek, and many other languages, certain particles never found singly, or uncompounded, and which are therefore called inseparable prepositions, as, in English, *be*, *for*, *fore*, *mis*, &c., which occur in such words as *be-stir*, *be-speak*; *for-bid*, *for-sake*; *fore-see*, *fore-know*; *mis-take*, *mis-deed*, &c.

PREROGATIVE, a word descended to us from the times of the Romans, or, rather, adopted from their language, to denote a certain power in the constitution of monarchical states. Its etymology is obvious, though the formation is not perhaps quite accordant with the analogies. *Præ* and *rogo* would seem to give the sense of precedence in asking, while prerogative means precedence in being asked, the right of having the consent first obtained of the party in whom the prerogative is vested, before any change shall be made in the matters comprehended within the prerogative. The term is confined to cases of dignity, to things indeed which affect the common interest when men are bound together in a political state; and though we might speak, as indeed men sometimes do, of the prerogative of the House of Lords, or the prerogative of the House of Commons, or even of the prerogative of the people, it is more usual to regard the word as belonging to the right which the crown possesses of being consulted, and its consent obtained, in whatever concerns the business of the nation.

Thus the consent of the sovereign must be first obtained before any new law can be made, or any change effected in the existing laws; and this appears to be prerogative in its purest state, and, indeed, in its only state of absolute purity. Other things which are now understood to be comprehended under the term prerogative, are only accretions to this the true prerogative, or things which have naturally shot forth out of it: unless we choose to take a view of the whole subject which shall take it wholly out of the scope of the etymological sense, and regard, as indeed many do, the word prerogative as standing to indicate the primordial and original power of any prince, the king of England for instance, which has been from time to time reduced and confined by the resistance, passive or active, of the subject. However the term may be chosen or applied, it now denotes not only the privilege of being consulted in any intended change of the law, and the consent obtained, but the right of making war or peace, of laying embargos, of commissioning officers in the army and navy, of sending and receiving ambassadors, of making treaties, of bestowing honours, conferring rank, and creating peers. To these are to be added the pardoning of offenders, which is sometimes called the prerogative of mercy; the calling, proroguing, and dissolving parliament, in which however the prerogative has been restrained by positive enactments; and, lastly, various rights which the sovereign enjoys as head of the church. All these things the crown does by its prerogative, without any application to parliament, or to any court or council whatever, though members of the Privy Council, those particularly who form what is called the Cabinet Council, or the ministers, are supposed to advise the sovereign in the exercise of the prerogative, and are sometimes made answerable by parliament for the injudicious or dangerous exercise of it. Theoretically however and nominally, these are prerogatives of the sovereign himself—rights inherent in him in virtue of his office, as much his as the subject has certain rights belonging to him, either as a member of the great community of Englishmen, or as belonging to some particular section to which he belongs, or to some particular office in which he is placed. In the mutual respect of each, and the forbearance of each to encroach on the rights or prerogatives belonging to each other, lies the balance of the English constitution; and out of it arises security to all, and the enjoyment of the blessings which belong to a well-ordered political community. When evils are perceived, when the subject claims rights which are incompatible with wholesome government, or when the crown claims rights as falling within the scope of any part of the prerogative which are opposed to the common good, there are remedial powers in the constitution which bring things right; and it is one of the most important functions of the two houses of parliament to see to this.

PREROGATIVE COURT, a court formerly held by each of the archbishops (or their officials) of England and Ireland. This court was held by virtue of the prerogative, for the purpose of trying the validity of wills, registering them, and granting probate or administration (and hence its title), which attached where one died possessed of bona notabilia, that is, of goods to the value of *5l.* (except in the diocese of London, where it is *10l.*) in one diocese or peculiar, and also goods, altogether of the same amount, in some other diocese or dioceses, peculiar or peculiars, within the same provinces- or where one, not being on a journey, died in one diocese or peculiar, possessed of goods of that amount in another diocese within the same province. One administration thus became sufficient; and the inconvenience and uncertainty of taking out administration in various dioceses, &c., were avoided. This court ceased to exist on the transference of the jurisdiction of the spiritual courts, in matters testamentary, to the crown by statute 20 & 21 Vict. c. 77.

PRESBYTERIANS (*πρεσβύτερος*, an elder) are professors of the Christian religion who believe that there is no order in the Church, as established by Christ and his Apostles, superior to that of Presbyters; that all ministers, being ambassadors of Christ, are equal by commission; that Presbyter or Elder, and Bishop, are only different names for the same person; and that Deacons are laymen whose office is chiefly to take care of the poor. A Presbytery (*πρεσβυτέριον*) they regard as a society of clerical and lay Presbyters, or, as they usually call them, Ministers and lay Elders. In support of these opinions they allege several passages of the New Testament. They affirm that the primitive form of church government was universally Presbyterian, and that this form, having, after the time of the Apostles, been supplanted by Episcopacy, was restored in some parts of Europe after the Reformation had begun.

The most noted Presbyterian Church of the present day is that of Scotland, called the Kirk. Presbyterianism was introduced into Scotland about 1560. Under Calvin's direction this discipline had already been put into operation at Geneva, whence it was brought by John Knox into his native land. King James I., who had been a Presbyterian in Scotland, and who embraced Episcopacy upon coming to the English throne, made Episcopacy, nominally at least, the religion of Scotland. In the reign of Charles I., Presbyterianism regained the ascendancy, but Episcopacy was once more declared the established religion at the restoration of Charles II. At the Revolution in 1688, Presbyterianism was re-established in Scotland by authority of Parliament, and thus it has continued to the present time.

The constitution of Presbyterianism in the established Church of Scotland is as follows:—The Kirk Session, consisting of the minister and lay or ruling elders of a parish or congregation, is the lowest court of judicature, the minister being, ex officio, the moderator or chairman. The Presbytery is next in authority, and consists of all the ministers of a certain district, and one ruling elder from each parish, who is chosen half-yearly. At the meeting of a Presbytery, a moderator is chosen out of the ministers. There are 84 Presbyteries, each consisting of parishes varying in number from 3 to 32. The Provincial Synods, of which there are 16, meet twice in the year, and are composed of the Presbyteries within the provinces which give name to the Synods. The highest authority is the General Assembly, which meets annually. [GENERAL ASSEMBLY OF THE CHURCH OF SCOTLAND.] Persons are appointed ministers by the laying on of the hands of the Presbytery. The maintenance of the clergy is regulated by the state, and they are nominated to livings by patrons. The Kirk has no Liturgy, no altar, and no instrumental music. Its doctrine is Calvinistic. At the Revolution the Westminster Confession was appointed the standard of the national faith, and it was enacted that no person should be admitted or continued a minister or preacher in this church, without subscribing to this Confession of Faith as his faith. By the Act of Union in 1707, the same subscription was required of all professors, principals, regents, masters, and others bearing office in any of the four universities of Scotland; but this has been repealed.

There are however many Presbyterians in Scotland who do not belong to the national establishment, although they maintain the same articles of faith as the members of the Kirk. [DISSENTERS.] The most important is the Free Church, which separated from the establishment in 1843, on a question of church patronage. [FREE CHURCH OF SCOTLAND.] The other sects (United Presbyterians, Reformed Presbyterians, Original Seceders, &c.) also preserve similar forms, and the differences between them chiefly relate to the question of national religious covenanting. [CAMERON, RICHARD, in BIOG. DIV.; UNITED PRESBYTERIAN CHURCH.]

The first Presbyterian congregation in England was formed at Wandsworth, near London, in 1572. In the reign of Charles I., 1645, it was proposed, in the treaty of Uxbridge, to make the Established Church of England Presbyterian, and the proposition was carried into effect by way of trial in 1646. In 1649 the Presbyterian discipline was sanctioned by parliament, and the Established church was Presbyterian till Episcopacy was restored with the restoration of Charles II. in 1660. [NONCONFORMITY.] The successors of the old Presbyterian congregations in England have in general become either UNITARIANS OF INDEPENDENTS: the congregations which are at the present day adherents of the Presbyterian form of church government belong to, or maintain friendly relations with, the Presbyterian churches of Scotland. The Synod of English Presbyterians, a separate organisation holding the principles of the Free Church of Scotland, is composed of about 100 congregations, forming 7 presbyteries; there are about 70 United Presbyterian congregations in England; and there are 3 presbyteries, comprising 17 congregations, which profess the principles of the Established Church of Scotland. In the north of Ireland, Presbyterianism is the prevailing faith, and there it is regularly constituted, though Episcopacy is the form of the Established Church. In the British Ccolonies there are numerous congregations of Presbyterians. The Presbyterians of the United States of America number about 6000 congregations.

PRESCRIPTION. "No custom is to be allowed, but such custom as hath been used by title of prescription, that is to say, from time out of mind. But divers opinions have been of time out of mind, &c and of title of prescription, which is all one in the law." (Litt., § 170.) According to this passage, "time out of mind," and "prescription," which are the same thing in law, are essential to custom: another essential to custom is usage. But there is a claim or title which is specially called prescription, and which is like custom so far as it has the inseparable incidents of time and usage; but it differs from custom in the manner in which it is pleaded, which difference shows the difference of the right. This claim is called prescription, because the plaintiff or defendant who makes it "prescribeth that," &c.; stating, after the word "prescribeth," the nature of his claim.

The following is an example of a prescription (Co. Litt., 114, a):—"I. S., seised of the manor of D. in fee, prescribeth thus: that I. S., his ancestors, and all whose estate he hath in the sayd manor, had and used to have common of pasture time out of mind in such a place, &c., being the land of some other, &c., as pertaining to the same manor." The claim of a copyholder of a manor for common of pasture in the manor, alleges a custom time out of mind within the same manor, by which all the copyholders of the manor have had and used common of pasture in it. The claim by prescription, then, is properly a claim of a determinate person: the claim by custom, as opposed to prescription, is local, and applies to a certain place, and to many persons, and perhaps, it may be added, to an indeterminate number, as the inhabitants of a parish. The following definition of prescription appears to be both sufficiently comprehensive and exact:—"Prescription is when a man claimeth anything for that he, his ancestors, or predecessors, or they whose estate he hath, have had or used anything all the time whereof no memory is to the contrary." (T. de la Ley.) From this definition it follows that prescription may be a claim of a person as the heir of his ancestors, or by a corporation as representing their predecessors, or by a person who holds an office or place in which there is perpetual succession; or by a man in right of an estate which he holds. It is said that certain persons, attorneys for instance, may prescribe that they and all attorneys of the same court have certain privileges; it seems indifferent whether this is called prescription or custom, but it is more consistent with the old definitions to call it prescription, since it is not a local usage, and it is by or on behalf of a determinate number of persons, that is, all the attorneys of a particular court. It is also said that parishioners may prescribe in a matter of easement, as a way to a churchyard, but not for a profit out of land: such a prescription, however, is not contained within the above definition, and is in all respects more properly a custom.

It is essential to prescription (subject to the limitations hereinafter mentioned) that the usage of the thing claimed should have been time out of mind, continuous, and peaceable. "Time out of mind" means, that there must be no evidence of non-usage or of interruption inconsistent with the claim and of a date subsequent to the first year of Richard I., which is the time of the commencement of legal memory. If it can be shown, either by evidence of persons living, by record, or writing, or by any other admissible evidence, that the alleged usage began since the first of Richard I., the prescription cannot be maintained. Repeated usage also must be proved in order to support the prescription, but an uninterrupted enjoyment for twenty years has been considered sufficient proof, where there is no evidence to show the commencement of the enjoyment. [PRESUMPTION.]

The thing prescribed for must be something definite. It must also be reasonable; and it must not be inconsistent with any established principle of law; for instance, it is said that a sheriff cannot prescribe for taking gifts for doing the duties of his office. It follows generally, that there can be no prescription to do any wrong or commit nuisance, or for a thing contrary to a statute. No prescription is good which is against the king's right (subject to the limitations hereafter mentioned), conformably to the maxim, Nullum tempus occurrit regi; yet a grant from the crown may be presumed.

Where a man prescribes for a thing which cannot be granted or aliened without deed, he must prescribe in himself, and in his ancestors, whose heir he is; and he cannot prescribe in himself and those whose estate he hath; for he cannot have their estate without deed or other writing which ought to be showed to the court. But of things appendant to a manor or to other lands or tenements, a man may prescribe that he and they whose estate he hath, have been seised of those things as appendant to the manor or to such lands and tenements time out of mind of man. And the reason is, that such manor or lands and tenements may pass by alienation without deed. (Litt. § 183.)

From the nature of the claim of prescription, it follows that a man cannot make a title to land by prescription, for the evidence of a title to land is quite different from and inconsistent with that of a thing claimed by prescription, which only applies to incorporeal things. A man may prescribe for all franchises and privileges which he may have, without a title appearing on record, as for waifs, estrays, wreck, treasure trove; and to have a park or warren, to have a fair, market, or right to toll, &c.

Nothing can be prescribed for at the present day that may not be the subject of grant; for the allegation of usage time out of mind must be usage of something which could originate in a lawful way. When, then, the claim of prescription is allowed, it is equivalent to admitting that there was an original grant which is now lost. (Luttrel's case, 4 'Rep.' 86.) It is however no proof of a grant.

A question has been raised whether the same thing may be claimed by prescription and by custom, which is nearly the same thing as saying, whether the same thing could be granted to all the inhabitants of a given place, and also granted to one person in that place, either in gross or in respect of a piece of land; as for instance, whether a private right of way may not exist together with a public right of road. (Blewett v. Tregonning, 3 A. & E. 586.) If *all* prescription supposes an original grant, it is an inconsistency to suppose a grant to A. and a grant of the same thing to A. and others with him.

There is some confusion in the books as to prescription and custom, and the real distinction between them has perhaps not always been observed. It seems immaterial whether the thing whose origin is unknown is called prescription or custom, for the two incidents of time and usage belong to both. Still there is the distinction as to the persons who claim, which has been already stated; and there is of course a difference in the evidence, which results from the difference in the persons claiming, or in whose right it is claimed.

A prescription may be lost or destroyed in various ways. If the thing in respect of which the prescription is claimed is destroyed, the prescription also is destroyed. A franchise by prescription is destroyed if the same liberties are granted by the king by charter. It may be lost by non-usage. But a prescription is not lost by changes which are immaterial and do not affect the nature of the claim: thus if a man prescribes for a watercourse to a fulling-mill, and he converts it into a grist-mill, he does not lose his right, which is generally to have a watercourse to a mill on a given site. And if a corporation should prescribe, and afterwards have a new name, it would not lose the right. (4 'Rep.,' 86.) When the ownership of the land and of the thing claimed out of or upon it are united in the same person, the prescription is destroyed.

Recent Acts have made some alterations as to prescription, and limited the time within which actions can be brought or suits instituted relating to real property. The 3 & 4 Will. IV. c. 27, applies to everything of a corporeal nature, which is land in the sense in which land is interpreted in that Act; but it only applies to those kinds of property of an incorporeal nature, which are advowsons, annuities, and rents. The 2 & 3 Will. IV. c. 100, applies only to cases of modus and exemption from tithes. The 2 & 3 Will. IV. c. 71, which is entitled "An Act for Shortening the Time of Prescription in certain cases," applies (§ 1) to "claims which may be lawfully made at the common law by custom, prescription, or grant to any right of common or other profit or benefit to be taken from or upon any land, &c., except such matters and things as are therein specially provided for, and except tithes, rents, and services;" (§ 2) "to any way, or other easement, or to any watercourse, or the use of any water," &c.; and (§ 3) to the use of light. No claim to the things comprised within this statute "shall, when such right, profit, or benefit (as is mentioned in § 1) shall have been actually taken and enjoyed by any person claiming right thereto, without interruption for the full period of thirty years, be defeated or destroyed by showing only that such right, profit, or benefit was first taken or enjoyed at any time prior to such period of thirty years; but nevertheless such claim may be defeated in any other way by which the same is now liable to be defeated; and where such right, profit, or benefit shall have been so taken and enjoyed as aforesaid, for the full period of sixty years, the right thereto shall be deemed absolute and indefeasible, unless it shall appear that the same was taken and enjoyed by some consent or agreement expressly made or given for that purpose by deed or writing." As to the rights enumerated in the second section, the terms of twenty and forty years are respectively fixed in the place of the terms of thirty and sixty years mentioned in the first section. Under the third section, which applies to lights, an absolute right to light may be acquired by twenty years' uninterrupted enjoyment, unless the use has been enjoyed by some consent or agreement made or given by deed or in writing. The eighth section provides "that when any land or water upon, over, or from which any such way or other convenient watercourse or use of water shall have been enjoyed or derived, hath been or shall be held under any term of life, or any term of years exceeding three years from the granting thereof, the time of the enjoyment of any such way or other matter as therein last mentioned, during the continuance of such term, shall be excluded in the computation of the said period of forty years, in case the claim shall within three years next after the end or sooner determination of such term be resisted by any person entitled to any reversion expectant on the determination thereof." Formerly it was necessary for all persons who claimed in respect of an estate and had not the fee, to claim in the name of the person who had the fee, but under the last-mentioned Act "it shall be sufficient to allege the enjoyment thereof as of right by the occupiers of the tenement in respect whereof the same is claimed, for such of the periods mentioned in the Act as may be applicable to the case, and without claiming in the name or right of the owner of the fee, as is now usually done."

The statute applies also to "any land or water of the king, his heirs, or successors, or any land being parcel of the duchy of Lancaster or of the duchy of Cornwall."

By the common law a man might prescribe for a right which had at any time been enjoyed by his ancestors or predecessors; but the statute of 32 Hen. VIII. c. 2, enacted that no person should "make any prescription by the seisin or possession of his ancestor, unless such seisin or possession hath been within threescore years next before such prescription made." This statute prevented any claim being made by prescription unless there had been seisin or possession within sixty years; but it still allowed the commencement of the enjoyment at any time within legal memory before the sixty years to be proved. The Act, 3 & 4 Will. IV. c. 100, directs that "the respective periods of years thereinbefore mentioned shall be deemed to be the period next before * some suit or action wherein the claim or matter to which such period may relate shall be brought into question" (§ 4); but it only excludes proof of commencement of enjoyment, and it only gives the absolute right, when the several periods of years, reckoning backwards from the time of some suit or action wherein the matter is brought in question, are completed; and it neither excludes the proof nor gives the absolute right if there has been an interruption, within the meaning of this statute, which has been submitted to or acquiesced in "for one year after the party interrupted shall have had notice thereof, and of the person making or authorising the same." In these cases, if there has been seisin or possession of the ancestor or predecessor within sixty years, the statute of Henry VIII. will still apply, and evidence of the commencement of enjoyment within legal memory may still be given.

The Acts here enumerated do not apply to a claim "of a manor, a court leet, a liberty, separate jurisdiction, treasure trove, wreck, waifs, and other forfeitures, fair, market, fishery, toll, park, forest, chace, or any privilege legally known as a franchise, as well as anything pertaining to those rights which come under the description of dignities or offices." (Mr. Hewlett's 'Reply, &c., to certain Evidence before the Select Committee of the House of Commons on Records, February, 1836.')

The term prescription is derived from the Roman law, but the meaning of the term in the Roman law is different. Blackstone says (ii, c. 17, note f), "This title of prescription was well known in the Roman law by the name of usucapio ('Dig.,' 41, tit. 3, s. 3), so called because a man that gains a title by prescription may be said *usu rem capere*." This remark is not correct. Usucapio in the Roman law was founded solely on possession as such [POSSESSION], and it applied only to "corporeal things:" "by the laws of the Twelve Tables usucapion of moveable things was complete in one year; and of land and houses in two years." (Gaius, ii. 42.) "To usucapion was afterwards added, as a supplement, the longi temporis praescriptio, that is, an exceptio (plea) against the 'rei vindicatio,' the conditions of which were nearly the same as in the case of usucapion." (Savigny, 'Das Recht des Besitzes,' p. 6.) The term praescriptio was properly applied to that which a plaintiff (actor) prefixed (praescripsit) to the formula by which he made his demand against a defendant, for the purpose of limiting or qualifying his demand. It seems afterwards to have been used as equivalent to exceptio or plea.

Bracton (ii., c. 22) treats of ownership acquired "sine titulo et traditione, et per usucaptionem, s. per longam continuam et pacificam possessionem;" but he adds that no time was legally fixed as necessary to make the title perfect, and it depended on the discretion of the justices. It appears, then, that the rule as to the time of prescription commencing from the 1st of Richard I. (A.D. 1189) was not established at the time when Bracton wrote, which was in the reign of Henry III. Bracton observes that "longa possessio," as above defined by him, "sicut jus parit jus possidendi et tollit actionem vero domino petenti;" or the actual possession gives in course of time the right to possess. [POSSESSION.] In the same chapter he treats of the mode of acquiring "possessio rei incorporalis, sicut possessio juris, viz. alicujus servitutis per patientiam que trahitur ad consensum, et longum usum et pacificum." Bracton then makes no distinction between a thing corporeal and incorporeal as to the mode of acquiring right by possession and long usage, nor does he use the word prescription.

(Comyns, *Prescription:* Viner's *Abridgment;* Starkie, *Law of Evidence;* Blackstone, ii., p. 255, Mr. Kerr's ed.)

PRESCRIPTION has, by the law of Scotland, a much wider operation than either by the civil law or the law of England, supplying the place of the Statute of Limitations in the latter system. It not only protects individuals from adverse proceedings which other parties might have conducted if the lapse of time had not taken place, but it in some instances creates a positive title to property. The prescription by which a right of property can be established is that of forty years—a period borrowed from the *Praescriptio quadraginta annorum* of the Romans. Whatever adverse right is not cut off by the other special prescriptions of shorter periods, is destroyed by the *long* prescription. It may be said generally to preclude the right of exacting performance of any claim, as to which no judicial attempt has been made to exact performance for forty years from the time when it was exigible. To create a title to real property, the long prescription must be both positive and negative. The party holding the property must, by himself or those through whom he holds, have been forty years in unchallenged possession of the property on a title ostensibly valid—this is called positive prescription; and the claimant and those whom he represents must have been forty years without an ostensible title, and must, by not judicially attacking it, have tacitly acquiesced in the possessor's title—this is called negative prescription. An action raised in a competent court interupts the long prescription. It is usually stated in the Scottish law-books that it is interrupted by the minority of any person who could challenge the opposing right; but it would be more correct to apply in this case the phraseology of the French lawyers, who say it suspends prescription, as the years of minority are merely not counted in making up the period of forty years, while, when there is a judicial interruption, a new period of forty years commences to run. When the prescription applies to a pecuniary obligation, payment of interest or an acknowledgment of the obligation will interrupt it.

The other and shorter prescriptions cut off particular descriptions of claims or methods of supporting them. By the vicennial or twenty years' prescription, holograph writings, not attested with the usual solemnities of Scottish writs, cease to "bear faith in judgment." An obligation of cautionary or suretyship is limited to seven years. Bills of exchange and promissory notes cease to have force after six years; but the debts which they represent, if they do represent debts, may be proved by other means. The quinquennial prescription cuts off all right of action, after the lapse of five years, on bargains provable by witnesses. It also protects agricultural tenants from a demand for rent after they have been five years removed from the land to which the demand applies. The triennial, or three years' prescription, is very important. It cuts off claims on account of goods or services, the three years running from the date of the last item of the account; and also claims for wages, each year's wages running a separate prescription, and ceasing to be exigible, if not pursued for, in the lapse of three years from the time when it became due, such claims being then only provable by the writing or oath, that is, admissive on oath of the defendant.

PRESS, PRINTING. [PRINTING.]

PRESSURE. To explain the use of this term in mechanics, we must remember its previous and common use. When we attempt to move matter, or when we sustain a weight, the effect is accompanied by a perception which is called *pressure*. The sense of touch is nothing but this perception; contact without pressure is not touch, and there are even weights too small to give the sense of touch. A small feather supported on the open palm is not felt, though it would fall to the ground if the palm were removed.

The word pressure is soon indissolubly connected with the notion of motion caused or prevented. Let the obstacle which is pressed suddenly break, and the hand which pressed must follow, unless the person who presses can take an instantaneous warning to cease his effort. Hence, whenever we see motion caused, prevented, or altered, we are apt to carry with us the notion that pressure is exerted. The weight in the scale of a balance is said to press the scale; not that we suppose the scale to have muscles to be acted upon, and nerves to carry news of the action to a living brain, but that we see a counteraction of the known tendency of the weight to fall, and know that if the counteraction were the work of a human agent, that agent would be conscious of the perception of pressure. Hence everything fitted to produce the sensation of pressure, such as a weight, the elasticity of a spring, &c., comes to be called a pressure, and the word loses its meaning of a perception conveyed, and takes that of an agent proper to produce that perception if the human being were situated so as to receive it.

This consideration is not unimportant, for a latent confusion between pressure as a perception and pressure as a cause proper to produce that perception has prevented many from a clear understanding of the Newtonian doctrine of gravitation, has caused some to reject it altogether, and has made one or two write books against it. We have in mechanics the word FORCE, which really means nothing but the cause of motion produced, altered, or prevented; but this word force having been used in two distinct senses, namely, both in the sense of pressure and in that of acceleration produced by pressure, it is sometimes necessary to have recourse to the word *pressure* instead of *force* where precision of language is required. The motion of the planets is continually altered: there must be a producing cause of that alteration, a force, an agent proper to produce the sensation of pressure in a human being who should interfere with it, if such a thing could be; or, in common language, a pressure. If it is found that the laws of alteration in a planet's motion are such that the pressure must always be directed towards the sun, and if we thence say that the sun attracts the planet, or pulls the planet towards it (pull and pressure being the same terms, or at least only differing in their original meaning by this, that a pull is made towards the agent, and a pressure from him), a person who thus learns the notion of attraction may, without absolutely attributing consciousness to the sun, obtain a rather mysterious notion of attraction from something remaining of the original sense of the word pull or pressure. This it is of course desirable that he should get rid of; but if, from failing to do so, he should be inclined to doubt of what is called attraction, he would do well to remember that by the same rule he should deny that a weight placed in the scale of a balance presses against the scale, or that a weight hung to a beam pulls the beam.

---

* Richards v. Fry, 7 A. & E. 698.

Having said thus much, nothing remains as to the manner of estimating pressures, except to give a reference to the articles Force, Mass, Momentum, Motion (Laws of), &c.

We thence collect that in problems of dynamics it is requisite to estimate pressure (in cases in which it cannot be balanced against a weight) by the velocity which it would produce or destroy in a given mass of matter, and in a given time: it being known that the weight of a mass means that pressure which, applied to the mass, would produce in one second 32·19 feet of velocity. An instance of this process occurs in Centripetal and Centrifugal Forces.

Pressure can only produce an effect in *time;* an instantaneous alteration of velocity (as noted in Impulse) being mechanically absurd. But if a pressure produce its whole effect in an imperceptible time, there is all the appearance of an instantaneous destruction or creation of velocity. Suppose a hammer, for instance, to strike an anvil with a velocity of 20 feet in a second. The instant the contact begins, both hammer and anvil begin to be compressed, and the compression begins at the rate of 20 feet a second. But the resistance to compression is enormous, and is a pressure which, though it takes time to destroy any velocity, yet will destroy a velocity of 20 feet a second in a very small fraction of a second. The moment the velocity is all destroyed the effort of the anvil and hammer (both of which are compressed) endeavouring to restore themselves, the continuation in fact of the pressure which destroyed the velocity, will give a velocity to the hammer in a contrary direction, or the hammer will rebound, as it is well known to do. In the appendix to Professor Whewell's 'Elementary Treatise on Mechanics' (third or fourth edition), a mathematical investigation of such problems (by Mr. Airy) will be found, upon highly probable hypotheses as to the constitution of matter. The following result of these hypotheses (which cannot be far wrong) will give an idea of the enormous pressures which are created in common cases of what is called *impact* :—If a column of iron three inches high be let fall on an anvil two feet high, from a height of eight feet, the compression of both hammer and anvil is about one-thousandth of a foot, and the pressure exerted at the moment when it is greatest is that of a quicscent column of iron similar to the hammer in its action, but of no less than 4000 feet high.

PRESSURE, CENTRE OF. When a fluid presses upon a surface, there is a point in that surface (known as the *centre of pressure*) at which, if a force be applied in the same line with the pressure of the fluid and equal to the whole of that pressure, but in a contrary direction, it will balance or counteract the whole pressure of the fluid. It is often of great importance to find the centre of pressure, and for the methods of doing so we must refer to Hydrostatics.

PRESUMPTION. A presumption may be defined to be a belief or inference as to the existence of a fact not actually known, arising from its necessary or usual connection with others which are known.

A fact may be proved by the immediate knowledge of the witnesses to it, which is called direct evidence. If it cannot be so proved, some other fact may generally be proved by direct evidence, from which the fact in question may often be inferred. If such other fact can be proved, and the existence of the fact in question can be inferred, such inference is a presumption. The inference may be either strictly logical or necessary, or it may be only probable, that is, the fact inferred may be true or it may not be true. If we cannot infer from the fact proved that the fact in question may be true, there can be no presumption at all as to such last fact. In all cases then, in order to establish a presumption, there must necessarily be an inference from a fact or facts; but the inference may be either necessary or probable. If necessary, it cannot, by the supposition, be disproved; if probable, it may either be disproved by evidence, or it may not be possible to disprove it for want of evidence, and yet the inference will still only be probable.

Presumptions which are necessary can hardly ever be considered as otherwise than conclusive in any system of law. Presumptions which are probable only may, by positive law, be made as conclusive as necessary presumptions, that is, it may not be permitted to disprove them when they could be disproved; or where such disproving evidence is wanted, and yet the inference is only probable, positive law may give it the same conclusive force as a necessary presumption.

A presumption, when established, that is, a fact when presumed, is legally the same as a fact proved in such manner as the particular system of law requires such fact to be proved. If then the law annexes any legal consequences to a given fact when proved, it annexes the same to it when the fact is legally presumed. It is only by virtue of legal consequences being annexed to facts that they become objects of jurisprudence. The establishment then of a presumption, in a legal sense, is only the establishment of a fact to which certain legal consequences are annexed.

In our own system, the presumption is sometimes made by a judge or a number of judges, and sometimes by a jury, but the consequences are the same. Some writers say that presumptions are either "legal and artificial" or "natural." They divide "artificial or legal presumptions" into two kinds, immediate and mediate. "Immediate are those which are made by the law itself directly and without the aid of a jury. Mediate presumptions are those which cannot be made but by the aid of a jury." Presumptions may therefore be divided into three classes: 1, Legal presumptions made by the law itself, or presumptions of law; 2, Legal presumptions to be made by a jury, or presumptions of law and fact; 3, Mere natural presumptions, or presumptions of fact."

The first class of presumptions, it is said, are either absolute and conclusive, or they may be rebutted by evidence to the contrary. The presumption of law that a bond was executed upon a good consideration cannot be rebutted by evidence, so long as the bond is unimpeached, that is, so long as it is admitted to be a bond. But though the law presumes that a bill of exchange was accepted on good consideration, it admits evidence to show that such was not the fact. Now this presumption of law is nothing more than a fact presumed by a judge or judges, to which fact so presumed, certain legal consequences are annexed or belong. It is however a very inaccurate expression to speak of a presumption of law; for, "when the law presumes or infers any fact to which a legal consequence is annexed from any defined predicament of facts, the law in effect indirectly annexes to that predicament the legal consequence which belongs to the presumed fact."

One presumption of law may be opposed by another, and the law, that is, the court, must then decide which is the stronger.

Presumptions of *mere law,* as shown, are such as are made by the court. There are instances of presumptions made by act of parliament, that is, the legislature has declared that a certain fact or facts, when proved, shall be conclusive proof of another unproved fact which is not a necessary, and, it may be, is often not a highly probable inference from the proved fact. A statute of 21 James I., c. 27 (now repealed), made proof of the concealment of the death of a bastard child by the mother conclusive evidence of her having murdered it, unless she could prove that it was born dead. And sometimes an act of parliament declares that a certain presumption shall not be allowed or made. (2 and 3 Wm. IV., c. 71, s. 6.) A presumption of mere law is sometimes called an *intendment* of law.

Presumptions of *law* and *fact* are artificial presumptions, recognised and warranted by the law as the proper inferences to be made by juries under particular circumstances. In other words, these are facts which the law, that is, the court, will allow a jury to presume from other facts proved by direct evidence. When the presumed fact is declared by the jury to be a real fact, or is implicitly contained in their verdict, the legal effect is the same. It is said that the inference (made by the jury) is never conclusive, which appears to mean that there are presumptions which are not necessary, and sometimes may not be highly probable, but they are still such as a jury may make (at least under the direction and advice of the court), and their verdict will be good. Thus a jury is required, or at least advised by a court to infer a grant of an incorporeal hereditament after an adverse enjoyment for the space of twenty years. The presumption of right in such cases is not however conclusive; in other words, it is not an inference of *mere law* to be made by the courts, yet it is an inference which the courts advise juries to make whenever the presumption stands unrebutted by contrary evidence. Such evidence in theory is mere presumptive evidence; in practice and effect it is a bar.

The third class, the natural presumptions of *mere fact,* are wholly independent of any artificial legal relations and connections, and differ from presumptions of mere law in this essential respect, that those depend upon or rather are a branch of the particular system of jurisprudence to which they belong; but mere natural presumptions are derived wholly by means of the common experience of mankind from the course of nature and the ordinary habits of society. This class of presumptions properly belongs to a jury, and yet the courts will sometimes make presumptions of this kind without the aid of a jury. These presumptions then are such as a jury may make without the advice or direction of the court, and it seems therefore to be a general rule, that whenever there is evidence on which a jury have founded a presumption according to the justice of the case, the courts will not grant a new trial.

Presumption then is either a positive rule by which a certain conclusion is declared by statute, or by the judges, or by the jury under the direction and advice of the judges, to follow from certain other proved facts; or it is a conclusion from certain other proved facts which a judge or a jury may make if they find the probative force of the proved facts sufficient to induce them to make the inference called a natural presumption, or presumption of mere fact. Presumptions therefore are incident to every head of law in which proof is required; and the presumptions which are positive rules of law are part of the law of the things to which they relate.

The term "præsumptio" occurs occasionally in the 'Digest,' and in the sense of an inference from a fact proved or admitted. ('Dig.', 22, tit. 3. s. 25.)

PRESUMPTIVE HEIR. [Descent.]

PRICE. [Value; Wages.]

PRIEST (Saxon, *preost*, from the Greek *πρεσβύτερος, an elder*), in its popular acceptation, is the name of a minister of religion in all ages and countries.

Priest is used to express the Greek *hiereus* (ἱερεύς) and the Latin *sacerdos*, which signify in general a sacrificer. Whatever may be the primitive meaning of the Hebrew word *cohen*, it is rendered in the Septuagint by ἱερεύς, and its usage plainly shows that it denotes a sacrificer. An elder, *zaken*, has πρεσβύτερος as its corresponding word. In Wycliffe's New Testament, which is a translation from the Vulgate, priest, answering to the Latin presbyter, several times occurs, where the authorised version has elder.

Priest in the formularies of the Church of England is used in its original sense of presbyter, and points out the second degree of the ministers, to be admitted to which a man must be, according to the 34th canon, of the age of "four and twenty years complete."

The existence of an official person to act in some way between the Deity and man appears among the earliest notices of history, whether sacred or profane. In the Book of Genesis, Melchisedec is named "Priest of the most high God." Among the Jews an order of men existed who were especially appointed by God to minister in holy things, and whose qualifications and functions are set forth at large in the writings of Moses. The Egyptians had great numbers of priests, who had lands in the time of Joseph. (Gen. xlvii. 22.) In the first ages of the Greeks, the same person was mostly their priest and king. In the course of time the office of priest became distinct, and sometimes women, as well as men, were appointed to this office. It is probable, however, that the most ancient priesthood among all nations was that which fathers or heads of families exercised over their own dependents; and thus it will appear that kingly government and sacerdotal authority of some kind or other would naturally spring from the paternal relation. (Shuckford's 'Connection of Sacred and Profane History.')

PRIMATE. [ARCHBISHOP.]

PRIME. A number is said to be prime when it is not divisible without remainder by any less number than itself, except unity. Thus 1, 2, 3, are of necessity prime; 4 is not, being divisible by 2; 5 is prime, and so are 7, 11, 13, 17, 19, 23, 29, 31, &c.

Large lists of prime numbers have been published [TABLES], but they are seldom possessed by the elementary student. As it is, however, frequently desirable to know whether a number not exceeding 10,000 is prime or not, we shall give a table to that extent, the manner of using which is as follows:—If we wish to know whether 2897 be a prime number, under the heading 2 and in the column 8 we look for 97, which we find there: whence the table shows that 2897 is a prime number. Again, by the same means we find that 1457 is not a prime number, the adjacent prime numbers being 1453 and 1459.

The distribution of the prime numbers does not follow any discoverable law, but it begins to be evident from the preceding table, that in a given interval the number of primes is generally less, the higher the beginning of the interval is taken. The following table will set this in a clearer light: the numbers in the first column mean thousands, and in the second column are found the numbers of primes which lie in the interval specified in the first column. Thus, between 10,000 and 20,000 lie 1033 primes.

In the first 10,000 numbers, upwards of 12 per cent. are primes; but between 900 thousand and a million, only 7¼ per cent. are primes. The annexed enumerations are taken from Legendre's Theory of Numbers, and were made from the large tables of primes given by Vega, Chernac, and Burkhardt. The only thing known relative to the proportions of prime numbers to others is that if x be a very large number, the number of primes contained between 0 and x is nearly $x \div (\log x - 1{\cdot}08366)$, $\log x$ being the Naperean logarithm. This very curious theorem was discovered empirically, that is, by looking for a formula which should nearly represent the results of tables. Legendre, in the work cited, gave proof that such a formula must have the form

Between	No. of Primes.	Between	No. of Primes.

$x \div (A \log x - B)$, but no reason has yet been given why A is 1, and B is 1·08366. Using the common logarithm, we find that the number of primes less than x is such a proportion of x as ·4342945 is of log x — ·470628, nearly. Thus, of all numbers less than a million of million of millions, only one out of 40 is prime, while the number of primes under the square of that number is one out of 82.

It thus appears that we might name a succession of numbers beginning with one so high, that a million, or any other number however great, of numbers should pass without containing one prime number. Nevertheless there cannot be an end to the prime numbers; for if so, let p be the last prime number, and let N be the product of all the prime numbers, 2, 3, 5, ... , p. Now every number is either prime or divisible by a prime; but $N+1$ is not divisible by 2, 3, 5, ... or p, since it leaves a remainder 1 in every such division. It is therefore prime, or there is a prime number $N+1$, greater than the greatest prime number p, which is absurd. The following are among the properties of prime numbers:—(1.) Every prime number (except 2) is odd, or of the form $2x+1$. (2.) Every prime is of the form $4x+1$ or $4x+3$, and a prime of the form $4x+1$ is always the sum of two squares. (3.) Every prime is of the form $6x+1$ or $6x+5$. (4.) No algebraical formula can always represent a prime number; but some formulæ show a long succession of primes: thus x^2+x+41 is prime from $x=0$ to $x=39$, both inclusive. (5.) If $2x+1$ be a prime number, and N any number which it does not divide, either N^x-1 or N^x+1 must be divisible by $2x+1$. (6.) If M and N be two prime numbers, and if $M=2x+1$, $N=2y+1$, then if x and y be both odd numbers, either $(M^y-1):N$ and $(N^x-1):M$ are both whole numbers, or $(M^y+1):N$ and $(N^x+1):M$ are both whole numbers. But if x and y be not both odd, then either $(M^y-1):N$ and $(N^x+1):M$ are both whole numbers, or else $(M^y+1):N$ and $(N^x-1):M$ are both whole numbers. This theorem is of considerable importance in the theory of numbers, and has been termed the law of reciprocity of prime numbers.

Two numbers are said to be prime *to one another*, when they have not any common measure except unity: as 36 and 55.

The prime factors of a number are those prime numbers which divide it. Thus, 360 being $2^3 \times 3^2 \times 5$, its prime factors are 2, 3, 5, of which the first enters three times, the second twice, and the third once. If $A, B, C, \dots$ be the prime factors of a number, and $a, b, c, \dots$ the number of times which they severally enter, the number is $A^a \times B^b \times C^c \times \dots\dots$ and the number of divisors which it admits of (unity and itself included) is $(a+1) \times (b+1) \times (c+1) \times \dots$. Let $A^a\, B^b \dots$ be N: then the number of numbers less than N, and prime to N, is

$$N \times \frac{a-1}{a} \times \frac{b-1}{b} \times \frac{c-1}{c} \times \dots$$

PRIME AND ULTIMATE RATIOS. [Ratios, Prime and Ultimate; Differential Calculus.]

PRIMERO, a game at cards, so called from a situation in the game. He who holds the *prime* (primero), that is, a sequence of the best cards and a good trump, is sure to be successful over his adversaries; hence its denomination. *Primero, prime,* and *primavista* were one and the same game.

Primero appears to have been one of the earliest games at cards played in England, and continued to be the most fashionable game throughout the reigns of Henry VIII., Edward VI., Mary, Elizabeth, and James. In the Earl of Northumberland's letters relating to the powder-plot, we find that Josceline Percy was playing at primero on Sunday, when his uncle, the conspirator, called on him at Essex-house.

Shakspere speaks of Henry VIII. playing at primero with the Duke of Suffolk.

(Singer's 'Researches into the History of Playing Cards,' 4to, Lond., 1816.)

PRIMOGENITURE may be defined to be that rule of English law by which a title of dignity or an estate in land comes to a person in respect of his being an eldest male. If a man dies seised of real estate, of which he had the absolute ownership, without having made any disposition of it by his last will, the whole descends to the heir at law, or customary heir; and the heir at law is such by virtue of being the eldest male person of those who are in the same degree of kindred to the person dying, or the representative of such eldest male. [Descent.] This is a case in which primogeniture operates. A common example of primogeniture is where a father dies absolutely entitled to real estate, and without disposing of it by will, in which case his eldest son takes it all. If land is settled or entailed on a man and his male issue, the eldest son takes the land by two titles, first as being a male, and next as being the eldest son. The law of primogeniture then only applies in the case of land when the owner dies without having made any disposition of it by will, or where the land is settled on a man and his male issue. It does not apply when the interest in land is a chattel interest, or a term of years, whatever may be its duration; nor does it apply when real estate descends to daughters as coparceners.

At present those who are the absolute owners of large landed estates seldom die without making a disposition of them by will. In the case of lands which are settled, the person in possession is generally tenant for life, and the inheritance is entailed on the eldest son. When the eldest son is about to marry, it is usual for the father and son to take the usual legal steps (which they can do as soon as the son is of age) to unsettle the estate and obtain the absolute ownership. They then resettle the estate, making the father tenant for life as before; the son, who was before tenant in tail, is also made only a tenant for life; and the inheritance is settled, as before, on the eldest son of the intended marriage. Such eldest son takes the estate, not as heir, and therefore not by the law of primogeniture, but he takes it as the person designated by the deed of settlement.

When a man happens to be tenant in tail, he usually takes the legal steps necessary (which he can do as soon as he is of age) to acquire the absolute ownership of the property, which he then generally settles again by deed or will, or disposes of absolutely.

It is usual in England to settle all large estates, and the object of the settlement is to keep the estates together, and to perpetuate them in one family; but there is a limit to this power of settlement. A man cannot, either by deed or will, settle his land, so as to prevent the absolute ownership of it from being obtained, for a longer period than a life or lives of persons in existence at the time when the settlement takes effect, and twenty one years more.

Lands in Gavelkind and Borough English are an exception to the general rule of law as to the descent of land.

The law of primogeniture then only operates in the cases already explained; and the system of settlements by which property is kept together in large masses is quite distinct in principle from the law of primogeniture. It is not the result of a law which favours primogeniture, but it is the result of the legal power which an owner of land has over it, and of the habits of the people. The various reasons which have laid the foundation of this habit, and which perpetuate it, are foreign to the consideration of primogeniture as a rule of law.

In Virginia, after the Revolution, an Act was passed for converting estates tail into fee-simple, and at the same time the law of primogeniture was abolished. These laws have so far been in accordance with or have acted on public opinion, that a parent by his will now generally makes the same disposition of his property as the law makes in case he dies intestate. (Tucker's 'Life of Jefferson,' i. 96, &c.)

(*Remarks on Primogeniture and Entails*; Hayes, *Introduction to Conveyancing.*)

PRIMULIN. A crystallisable non-azotised matter of unknown composition, found in the root of the primrose.

PRIMUM MO'BILE, the name given in the old astronomy to the imaginary sphere by the motion of which diurnal motion was given to the heavens. [Ptolemaic System.]

PRINCE is the Latin word *princeps*, which was originally used to denote the person who was entitled princeps senatus in the Roman State. He seems to have been originally the custos of the city, and his office was one of importance. Subsequently it became a title of dignity, and the princeps was named by the censors. (Liv. xxvii., 2.) In the senate he gave his opinion first after the magistratus. Augustus and his successors adopted the title of princeps, as a name that carried no odium with it: and this became henceforward the characteristic title of the master of the Roman world. Accordingly the constitutions of the emperors are called principum (Gaius i. 2) or principales. The word princeps is formed similarly to anceps, municeps, &c., and contains the same element as "primus." In the course of time the word prince, which is derived from princeps, has come to be applied to persons having personal pre-eminence, and especially to certain sovereigns of smaller states possessing either perfect independence of all others or enjoying under some superior high political rights. Of the first kind were the old sovereigns of Wales, who, under the name of princes, enjoyed the same right and power which belong to kings; and of the second, the heads of certain states of Germany, comprehended in the great Germanic confederation. But the word seems not to have acquired so definite a sense as that which belongs to king, duke, marquess, earl, and some others of the class; but rather to denote persons of eminent rank in certain states, as in Prussia, Russia, Italy, and other continental states, where no sovereignty, properly so called, comes along with it, or persons who are junior members of sovereign houses, as the younger members of the ducal families of Saxe and Anhalt. Frequently, however, such members have specific titles given, such as duke, count, &c., but never prince.

In England it has sometimes been the practice of the heralds to speak of a duke as the high and mighty prince; but the word seems rather to be restricted among us in its application to persons who are of the blood-royal, that is, a son, grandson, or nephew of a king; and it would probably be extended to the remote male posterity, though no such case has arisen in the course of the last three centuries. But in its application it is merely a term of common parlance, not being conferred, like the title of duke, in any formal manner; and even the precedence which is given to blood-royal has respect to birth, and not to the enjoyment of this word as a title of honour. The eldest son of the sovereign is however made Prince of Wales by a special act of creation; the younger sons are princes until they have other titles conferred; the daughters continue princesses.

PRINCE'S METAL. A kind of brass composed of 75 parts of copper and 25 parts of zinc.

PRINCIPAL. [Agent.]

PRINCIPAL, the name of a stop or row of metal pipes in an organ, tuned an octave higher than the diapason, an octave lower than the fifteenth, and serving to blend the two, as well as to augment the volume of sound.

PRINCI'PIA, the contracted title of the 'Philosophiæ Naturalis Principia Mathematica,' the great work of Newton, the publication of which is the most remarkable known epoch in the history of science. The title-page of the first edition is: 'Philosophiæ Naturalis Principia Mathematica. Autore Is. Newton, Trin. Coll. Cantab., Soc. Matheseos Professore Lucasiano, et Societatis Regalis Sodali. Imprimatur. S. Pepys, Reg. Soc. Præses, Julii 5, 1686. Londini Jussu Societatis Regiæ ac Typis Josephi Streater. Prostat apud plures Bibliopolas. Anno MDCLXXXVII.'

We entirely pass over the common story of the fall of an apple. [NEWTON, in BIOG. DIV.] It appears in the rough copy left among Newton's papers of the information furnished to Fontenelle for his *éloge* of Newton: but as Fontenelle did not give it, though very much given to anecdote, it may be inferred that Mrs. Conduitt, Newton's niece, struck it out before it was sent. It is clear however that Newton first thought on the subject in 1666. With reference to the story of his laying by the theory until Picard's measure of the earth was brought to his notice in 1682, it appears that Picard's 'Mésure de la Terre' was published in 1672, and much discussed at the Royal Society in the years following.* Moreover Dr. Pemberton, who derived his information from Newton himself, states most explicitly (in his preface) that a letter from Hooke gave occasion to his resuming his old thoughts, and that he then used Picard's measure. This letter from Hooke, the subject of which was the curve in which a falling body descends to the earth, taking into account the earth's motion, is clearly made out to have been written in 1679, which is therefore the date of Newton's resumption of his attempt, not 1682, as generally stated. The new attempt, as every one knows, was more successful, but Newton did not write any treatise nor contemplate any publication; he traced out the foundation of his system, and threw aside his papers. In January,† 1684, Halley had concluded, from Kepler's third law, that the centripetal force on the planets (supposed to move in *circles*) was as the inverse square of the distance. Not being able to proceed further, he applied to Hooke and Wren, the former of whom professed to have solved the whole problem, but would communicate nothing; the latter declared that he had long given over the question from inability to succeed. In August following, Halley paid a visit to Newton at Cambridge, who informed him that he had solved the problem, but *was not able to lay his hand on the papers which contained his solution*, so completely had he thrown the subject aside. After Halley's departure, he worked the theorems out again, and transmitted them to Halley through Mr. Paget, the mathematical master at Christ's Hospital. On receipt of this communication, in November, Halley immediately paid another visit to Cambridge, to gain more information, and to induce Newton to pursue the inquiry. December 10, 1684, Halley stated at the Royal Society that "he had lately seen Mr. Newton at Cambridge, and that he had shown him a curious treatise 'De Motu,' which, upon his desire, he said was promised to be sent to the Society, to be entered upon their register." Halley and Paget were accordingly deputed to keep Newton in mind of his promise (a singular proceeding, showing how well the Society knew Newton's indifference about communicating), and the consequence was, that about the middle of February, 1685, a communication (that previously made to Halley, enlarged), entitled 'Isaaci Newtoni Propositiones de Motu,' was sent and registered: it contains what were afterwards the main theorems of the early sections of the Principia, direct and inverse, relating to centripetal forces. No Principia as yet existed, and even this basis had only recently been written down satisfactorily. Newton writes to Mr. Aston, Sec. R.S., in acknowledging the news of the above entry, "I designed them for you before now, but the examining several things has taken a greater part of my time than I expected, and a great deal of it to no purpose. And now I am to go into Lincolnshire for a month or six weeks. *Afterwards I intend to finish it* as soon as I can conveniently." (February 23, 1685.) On this Mr. Rigaud well remarks, "The Principia was not a protracted compilation from memoranda which might have been written down under the impression of different trains of thought: it had the incalculable advantage of being composed by one continued effort, during which the mutual bearing of the several parts was vividly present to the author's mind." On the 21st of April, 1686, Halley announced to the Royal Society that Mr. Newton "had an incomparable Treatise on Motion almost ready for the press;" and on the 28th of the same month Dr. Vincent‡ presented the manuscript of the first book to the Society, who referred the question of printing to the Council, and the production of a report upon the contents to Halley. May 19, the Society decided that the work should be printed forthwith in quarto, &c.; and hence it has always been supposed that the Society paid the expenses of printing, though the title-page only bears "jussu Societatis," &c., and not "jussu et sumptibus," as usual where it bore the expenses. But Mr. Rigaud quotes the minute of the *Council* of the Society of the 2nd of June, confirming the vote of the *Society* to the extent of resolving "that Mr. Newton's book be printed," but adding that "E. Halley shall undertake the business of looking after it, *and printing it at his own charge, which he engaged to do.*" The fact was, that when the Council came to consider the Society's vote of the 19th of May, they found there was no money; a work of Francis Willughby, 'De Historia Piscium,' published "jussu et sumptibus," in 1686, had so reduced their funds, that they were obliged to pay their officers in copies of this very book about fishes.

In the meanwhile arose a controversy with Hooke, the universal claimant, who, when the first part of the manuscript was presented by Vincent, asserted that he had discovered the law of the inverse squares, and had communicated that and other discoveries to Newton. The heads of the paper on which he founds his claim are given at length in HOOKE, ROBERT, in BIOG. DIV., and they show that though he had (in common with several others) some very correct notions on the subject, he had not even arrived at the knowledge of the law of the inverse squares, though that had been propounded by BOUILLAUD [BIOG. DIV.]. Mr. Rigaud enters at great length into this question; if we were to do the same, we should take an advanced position, and before we attempted to show that Hooke did not write any part of the substance of the Principia, we should require reasonable proof that he would have been able to read and understand the mathematical part of it when written: and not until this had been given, which we are convinced could not be given from Hooke's writings, should we consider it necessary to enter on the first point. Had it not been for Halley, this trumpery claim of Hooke's would have produced serious consequences. Newton, easily disgusted by controversy, and having observed that physical questions generally gave rise to it, proposed (in a letter to Halley, June 20, 1686) to omit the third book altogether, which contains the actual application of the first two books to the existing universe. He says, "The third I now design to suppress. Philosophy is such an impertinently litigious lady, that a man had as good be engaged in lawsuits as have to do with her. I found it so formerly, and now I have no sooner come near her again, but she gives me warning. The two first books, without the third, will not so well bear the title of 'Philosophiæ Naturalis Principia Mathematica,' and therefore I had altered it to this,—'De Motu Corporum Libri Duo,' but upon second thoughts, I retain the former title. 'Twill help the sale of the work, which I ought not to diminish now 'tis yours." Halley had to soothe this irritation, and prevent the consequences; and as the letter in which he did this is very curious, and has never been printed altogether, except by Mr. Rigaud, the surpassing interest which everything connected with the Principia excites will justify our giving it entire, particularly as it is the original voucher for several of the most important circumstances connected with the publication:—

"London, 29 June, 1686.

"Sir,—I am heartily sorry that in this matter, wherein all mankind ought to acknowledge their obligations to you, you should meet with anything that should give you disquiet; or that any disgust should make you think of desisting in your pretensions to a lady whose favours you have so much reason to boast of. 'Tis not she, but your rivals, envying your happiness, that endeavour to disturb your quiet enjoyment; which, when you consider, I hope you will see cause to alter your resolution of suppressing your third book, there being nothing which you can have compiled therein, which the learned world will not be concerned to have concealed. Those gentlemen of the Society to whom I have communicated it, are very much troubled at it, and that this unlucky business should have happened to give trouble, having a just sentiment of the author thereof. According to your desire in your former, I waited upon Sir Christopher Wren, to inquire of him, if he had the first notion of the reciprocal duplicate proportion from Mr. Hooke. His answer was, that he himself very many years since had had his thoughts upon the making out the planets' motions by a composition of a descent towards the sun, and an impressed motion; but that at length he gave it over, not finding the means of doing it. Since which time Mr. Hooke had frequently told him, that he had done it, and attempted to make it out to him; but that he never was satisfied that his demonstrations were cogent. And this I know to be true, that in January, 1683-4, I, having, from the considerations of the sesquialter proportion of Kepler, concluded that the centripetal force decreased in the proportion of the squares of the distances reciprocally, came on Wednesday to town, where I met with Sir Christopher Wren and Mr. Hooke, and falling in discourse about it, Mr. Hooke affirmed, that upon that principle all the laws of the celestial motions were to be demonstrated, and that he himself had done it. I declared the ill-success of my own attempts; and Sir Christopher, to encourage the inquiry, said that he would give Mr. Hooke, or me, two months' time to bring him a convincing demonstration thereof; and, besides the honour, he of us, that did it, should have from him a present of a book of forty shillings. Mr. Hooke then said, that he had it, but he would conceal it for some time, that others trying and failing might know how to value it, when he should make it public. However, I remember that Sir Christopher was little satisfied that he could do it; and though Mr. Hooke then promised to show it him, I do not find that in that particular he has been so good as his word. The August following, when I did myself the honour to visit you, I then learnt the good news that you had brought this demonstration to perfection: and you were pleased to promise me a copy thereof, which the November following I received with a great deal of satisfaction from Mr. Paget; and thereupon took another journey to Cambridge, on purpose to confer with you about it, since which time it has been entered upon the Register books of the Society. As all this passed, Mr. Hooke was acquainted with it, and according to the philosophically ambitious temper he is of, he would, had he been master of a like demonstration, no longer have concealed it, the reason he told Sir Christopher and me now ceasing. But now, he says, this is but one small part of an excellent system of nature, which he has conceived, but has not yet completely made out, so that he thinks not fit to publish one part without the other. But I have plainly told him, that unless he produce another differing demonstration, and let the world judge of it, neither I nor any one else can believe it. As to the manner of Mr. Hooke's claiming the discovery, I fear it has been represented in worse colours than it ought; for he neither made public application to the Society for justice, nor pretended you had all from him. The truth is this: Sir John Hoskyns, his particular friend, being in the chair when Dr. Vincent presented your book, the Doctor gave it its just encomium both as to the novelty and dignity of the subject. It was replied by another gentleman, that you had carried the thing so far, that there was no more to be added. To which the Vice-president replied, that it was so much the more to be prized, for that it was both invented and perfected at the same time. This gave Mr. Hooke offence, that Sir John did not, at that time, make mention of what he had, as he said, discovered to him; upon which they two, who till then were the most inseparable cronies, have since scarce seen one another, and are utterly fallen out. After the breaking up of that meeting, being adjourned to the coffee-house, Mr. Hooke did there endeavour to gain belief, that he had some such thing by him, and that he gave you the first hint of this invention. But I found, that they were all of opinion, that, nothing thereof appearing in print, nor on the books of the Society, you ought to be considered as the inventor. And if in truth he knew it before you, he ought not to blame any but himself, for having taken no more care to secure a discovery which he puts so much value on. What application he has made in private, I know not; but I am sure that the Society have a very great satisfaction, in the honour you do them, by the dedication of so worthy a treatise. Sir, I must now again beg you, not to let your resentments run so high, as to deprive us of your third book, wherein the application of your mathematical doctrine to the theory of comets and several curious experiments, which, as I guess by what you write, ought to compose it, will undoubtedly render it acceptable to those who will call themselves Philosophers without Mathematics, which are much the greater number. Now you approve of the character and paper, I will push on the edition vigorously. I have sometimes had thoughts of having the cuts neatly done in wood, so as to stand in the page with the demonstrations. It will be more convenient, and not much more charge. If it please you to have it so, I will try how well it can be done; otherwise I will have them in somewhat a larger size than those you have sent up. I am, Sir, your most affectionate humble servant, "E. HALLEY."

---

* Rigaud mentions that Newton must have been acquainted with the measures of Snell and Norwood, the result of the former of which appears in his own edition of Varenius. The latter, there can be no doubt, he did not trust; and as to the former, we have shown [MILE] that in this very edition of Varenius, he had allowed gross errors to pass as to the measures of his own country. It may be inferred that he had not much to do with the details of it.

† That is, what we call 1684; Halley writes 1683-4. [PERIODS OF REVOLUTION.] All the following dates are for a year beginning in January.

‡ This gentleman has been (wrongly) supposed to have been the husband of a lady to whom Newton was attached in early life.

The authorities on this subject are—1, Rigaud, 'Historical Essay on the First Publication of the Principia,' Oxford, 1838, 8vo.; 2, Edleston, 'Correspondence of Sir I. Newton and Prof. Cotes,' London, 1850, 8vo.; 3, Brewster, 'Memoirs of Sir I. Newton,' London, 1855, 2 vols. 8vo. Rigaud's research was of the most acute and accurate character. Mr. Edleston has added a biography in the form of *annals* with notes, the most convenient reference on Newton which exists: and his researches, especially those made in Trinity College, have been laborious and successful. Sir D. Brewster had the celebrated Portsmouth papers in his possession, and has produced the most detailed life of Newton which exists. An immense deal has been done for the biography of Newton in the last twenty-five years: but the subject will never be finally settled until the Portsmouth papers have been allowed to undergo the most searching and leisurely scrutiny from men of all opinions on disputed points.

Newton had completed the first draught of the work by the end of 1685, though none of it was sent till April, 1686. The third book was presented to the Society, April 6, 1687, in proof, probably, since the whole was published (at ten or twelve shillings a copy) about Midsummer, 1687. The order of the Council of the Society to license the book was made on June 20, 1686, and the imprimatur of Pepys was dated July 5.

The part which Halley had in the matter would alone immortalise his name. He found out the ability of Newton to write such a work, prevailed upon him to write it, took charge of the publication, prevented the author from materially mutilating it in disgust, paid the expenses of printing, at a time when, owing to his father's death and consequent litigation, he had nothing to spare (which never happened to him before or after), gave a copious explanation of it in the Philosophical Transactions, and is generally admitted to have been for a long time the only person in Europe who showed that he thoroughly appreciated the value of the work, and knew the place it must occupy in the history of discovery.

The interest attached to the second and third editions of the Principia (superintended by Cotes in 1713, and by Pemberton in 1726) is considerable, with reference to the alterations made in them by Newton. It would not however be worth while to specify these alterations, which are numerous, some in correction of errors, others in extension of views. With reference to the suppression of the celebrated Scholium, see COMMERCIUM EPISTOLICUM and FLUXIONS.

The Principia of Newton contains the dedication to the Royal Society, a short preface, verses by Halley in honour of Newton, definitions, axioms, a first book on unresisted motion, a second on resisted motion, and a third on the system of the universe. Halley's verses were somewhat altered by Bentley in the second edition, but the original readings were very nearly restored in the third. Newton wrote a short preface for each of the editions, and Cotes one of considerable length for the second. The dates of the Newtonian prefaces are, May 8, 1686; March 28, 1713; January 12, 1725–6. The following is the description of the contents of the third edition:

The definitions comprise, 1. Quantity of matter measured by density and volume jointly. 2. Quantity of motion [MOMENTUM] by velocity and quantity of matter jointly. 3. Vis insita, or vis inertiæ. [INERTIA.] 4. Vis impressa, or external force. 5. Centripetal force. 6. Absolute magnitude of centripetal force. 7. Accelerating force. 8. Moving force. A scholium is added on time, space, and motion, the latter considered absolutely and relatively.

The axioms are the three laws of motion [MOTION, LAWS OF] and certain corollaries, namely:—1. The composition of velocities and forces. 2. Their resolution, and deduction of the property of the lever. 3. Momentum of a system in a given direction not changed by the mutual action of the parts. 4. Nor the motion of the centre of gravity. 5. Relative motion of bodies not altered by absolute motion of the space they move in. 6. Nor by equal and parallel accelerating forces applied to all. A scholium is added, containing the experimental verifications of the third law in the cases of impact, attraction, and operation of machines.

THE FIRST BOOK * on unresisted motion, consists of fourteen sections, and ninety-eight propositions. The numbers in parentheses refer to the propositions.

Section 1 contains eleven lemmas and a scholium. This section is explanatory of Newton's peculiar mode of reasoning, which subject, with the contents of this section, will be treated under RATIOS, PRIME AND ULTIMATE.

Section 2. On Centripetal Force. (1) Equal areas are described in equal times. Six corollaries on the comparison of velocities and forces; the former inversely as the perpendiculars on the tangents, the latter as the sagittæ of arcs described in equal times. (2) If equal areas be described in equal times about a centre, fixed or moving straightly and uniformly, the force is centripetal. Two corollaries and scholium. (3) In equiareal motion of a point about a moving centre, that point is acted on by a centripetal force, and by all the accelerating forces which act on the centre. Four corollaries and scholium. (4) In different circles uniformly described, force varies as $(\text{vel})^2 \div \text{rad}$. Nine corollaries and scholium indicating the deduction in the case of the planets. (5) Given the velocities in different parts of an orbit, to find the centre of force. (6) Centripetal force in the middle of a small arc is as sagitta $\div (\text{time})^2$. Five corollaries; various ways of comparing forces. (7) The orbit circular, centre anywhere within, to find the law of force. 3 Cor. (8) Ditto, ditto, where the forces act in parallel lines. Scholium; same considerations apply to other conic sections. (9) Law of force in equiangular spiral. Lemma 12 (the numbering of the lemmas runs on from the first section). Equality of parallelogram about conjugates in conic sections. (10) Law of force in ellipse about the centre. 2 Cor. and Schol.; extension to the parabola.

Section 3. Motion in conic sections about the focus. (11) Law of force in ellipse about focus. (12) Same for hyperbola. Lemma 13, Latus rectum in parabola always four times focal distance. Lemma 14, Perpendicular on tangent of parabola, mean between focal distances of point of contact and vertex. 3 Cor. (13) Law of force in parabola about focus. 2 Cor. (14) In conic sections about same focal centre, latera recta are in duplicate ratio of areas described. 1 Cor. (15) In ellipses, periodic times are in sesquiplicate ratio of major axes. 1 Cor. (16) And velocities are as perpendiculars on tangents inversely, and subduplicate ratio of latera recta directly. 9 Cor.; comparison of velocity in conic section and circle. (17) Given initial position and velocity, required conic section described. 4 Cor. and Schol.

Section 4. On finding conic sections from a given focus, and *Section* 5. On finding conic sections of which no focus is given. These sections, which carry on the lemmas from 15 to 27, both inclusive, and the propositions from (18) to (29), both inclusive, are entirely geometrical exercises in drawing conic sections through given points, or touching given straight lines, &c.: the results are hardly of use, even in the rest of the work, and a particular reference would now be of no use whatever, though the sections themselves are highly interesting to the geometrical inquirer.

---

* This description is for reference, not for explanation, and is therefore very briefly given. To give an account of every corollary and scholium would have extended the article to a great length; hence only some of the more important of them are described. But the references to other articles in this work are for the elementary student. At the same time, a young student who can as much as understand the meaning of the terms will learn more about the Principia from this table of contents than from anything except the Principia itself.

Section 6. On finding the motion in a given orbit. (30) To find the place of a body in a parabola at the end of a given time. 3 Cor. Lemma 28. There is no oval figure whose area contained being any two radii, can be obtained by an equation in finite terms. [QUADRATURE OF THE CIRCLE.] 1 Cor.; relates to the ellipse. (31) To find the place of a body in an ellipse at the end of a given time. Scholium; approximate method.

Section 7. On rectilinear ascent and descent. (32) Required the space described in a given time by a body descending towards a centre.* Three cases, derived from the three conic sections. (33) Law of the velocity in the preceding, in the cases derived from the ellipse and hyperbola. 2 Cor. (34) The same in the case derived from the parabola. (35) An equable description of certain areas in the conic sections just alluded to takes place during the motion. (36) The time of the whole descent of a body from rest. (37) The time of the whole descent of a projected body. (38) Velocity and time determined in descent to a centre, the force being as the distance. 2 Cor. (39) Granting the quadrature of curves [QUADRATURE], and the law of force being any whatever, to determine the time and velocity at any point of a descent. 3 Cor.

Section 8. Determination of the orbit under any law of centripetal force. (40) The velocity at a given distance is always the same both in an orbit and a descent, if it be the same at any one distance in both. 2 Cor. (41) Granting the quadrature of curves, to find the orbit and the time of describing an arc, under any law of force. 3 Cor. (42) The same, the initial velocity and direction being given.

Section 9. On the motion of bodies in moveable orbits, and on the motion of the apsides. (43) How to make a body revolve equiareally in both a moving orbit and in the same fixed. (44) The difference of forces in the two cases is as the inverse cube of the distance. 6 Cor.; mostly exhibiting the conclusion in algebraical form. (45) To find the motion of the apsides in orbits nearly circular. 3 Examples; 2 Cor.

Section 10. On the motion of bodies in given surfaces, and on pendulous motions. (46) Given a plane, and a centre of force external to it, to find the motion of a point parallel to that plane, the law of force being any whatever. (47) The force in the last being as the distance, the orbit parallel to any plane must be an ellipse, and in all such ellipses the time of revolution is the same, and the same as that of a double ascent and descent. Schol. (48) and (49) Rectification of the epicycloid and hypocycloid. 3 Cor. (50) Way to make a body oscillate in a given hypocycloid. Cor. (51) If the force tending to the centre of the fixed circle in such an oscillation be as the distance, the times of all such oscillations are equal. Cor. (52) Determination of the velocity and time at any point of such an oscillation. 2 Cor.; the second being an application to the common cycloid. (53) On a given curve, to find the law of force which gives isochronous oscillations. 2 Cor. (54) A body moving on a rigid curve, under a given law of centripetal force, to find the time of its oscillations. (55) If a body move on a surface of revolution, the centre of force being in the axis, equal areas are described in equal times on a plane perpendicular to the axis. Cor. (56) To find the curve described in the last case.

Section 11. On the motion of bodies centripetally attracted to each other. (57) Two bodies, mutually attracting, describe similar figures about each other and about their common centre of gravity. (58) And with the same forces, the same curve may be described by either about the other at rest. 3 Cor. (59) Relation of the periodic times about the centre of gravity, and of one body about the other at rest. (60) In the same two cases, relation of the axes of the ellipses described. (61) And for any law of force, the bodies move round their centre of gravity as if a third body were placed in that centre, attracting with the same law of force. (62) Determination of the descent towards each other of two mutually attracting bodies. (63) Determination of the orbits of two such bodies, with given initial velocity and direction. (64) The force being as the distance, determination of the relative motions of several bodies. (65) The force being inversely as the square of the distance, and there being several bodies, one may move round another in an ellipse *nearly*, and describe areas nearly proportional to the times. 3 Cor. (66) The celebrated proposition of the three bodies, showing the diminution of the disturbance by the third body attracting both the others. (In the corollaries following, let the earth and moon, for distinctness sake, be the two bodies, and the sun the disturbing body: but let it be remembered that Newton does not mention the name of any planet nor hint at any application.) Cor. 1, If the earth had more satellites, the same proposition would apply to one as disturbed by the rest. Cor. 2 and 3, The moon moves quickest, cæteris paribus, in conjunction and opposition, and slowest in quadratures. Cor. 4, The moon's orbit is more curved in quadratures than in syzygies. Cor 5, Hence, excentricity being excluded, the moon is farther from the earth in quadratures than in syzygies. Cor. 6, Explanation of the effect of the variation of the sun's distance on the moon's period. Cor 7, The moon's apsides progress and regress, but the former more than the latter. Cor. 8, Effect of the position of the apsides with respect to the sun. Cor. 9, Effect on the excentricity of the moon's orbit. Cor. 10 and 11, Effect on the inclination and place of the nodes. Cor. 12, Disturbance rather greater in conjunction than in opposition. Cor. 13, The same species of effect produced whether the disturbing body is the greater or the less of the three. Cor. 14, 15, 16, 17, On the dependence of the disturbing forces on the distance of the disturbing body. Cor. 18, 19, 20, 21, 22, Explanation of precession of equinoxes and tides. (67) The disturbing body describes areas more nearly proportional to the times about the centre of gravity of the other two bodies than about either of them, and an orbit more nearly elliptic. (68) And the more so on account of its attracting the other bodies. Cor. (69) The attracting forces of bodies are, cæteris paribus, as their masses. 3 Cor. and Scholium.

Section 12. On the attractions of spherical bodies. (70) A particle placed inside a spherical shell is in equilibrium. (71) Spherical shells attract as if their whole masses were collected at their centres. (72) The attractions of spheres on points similarly placed with respect to them are as their diameters. 3 Cor. (73) At different internal points of a solid sphere the attractions are as the distances from the centre. Schol. (74) Solid spheres attract as if the whole masses were collected at their centres. 3 Cor. (75) The same of spheres attracting spheres. 4 Cor. (76) The same of spheres consisting of concentric layers of unequal density. 9 Cor. (77) The same is true when the forces of particles to each other are as their distances. (78) With the same law, the same is true of spheres consisting of concentric layers. Cor. and Schol.: Lemma 29. (79); (80) 4 Cor.; (81), 3 Exam.; (82): these show the method of finding the attraction of any sphere on a point without it, for any law of force. (83) The force being as the inverse nth power of the distance, to find the attraction of a segment of a sphere on a particle at its centre. (84) The same when the particle is not in the centre. Schol.

Section 13. On the attraction of non-spherical bodies. (85) If the attraction of the body on a contiguous particle be much greater than on one at a little distance, the attraction of the molecules of the attracting body diminishes in a higher ratio than the inverse square of the distance. (86) And the hypothesis of the last is a consequence, if the attraction of the molecules diminishes as the inverse cube of the distance, or faster. (87) If two similar bodies of the same material attract two molecules proportional to themselves and similarly placed, the attractions of the molecules on the two bodies will be proportional to their attractions on their similar particles similarly placed. 2 Cor. (88) If the particles of a body attract a molecule with forces as their distances, the whole attraction of the body will be towards its centre of gravity, and equal to that of a sphere equal to the body, and having its centre in that centre of gravity. Cor. (89) And the same if there be several bodies. Cor. (90) To determine the attraction of a circle on a point in its axis. 3 Cor. (91) To determine the attraction of a solid of revolution on a point in its axis. 3 Cor. relating to cylinders and spheroids. (92) Given an attracting body, to find (experimentally) the law of attraction of its particles. (93) If particles attract as the inverse nth power, a solid bounded by a plane, but indefinitely extended in all directions on one side of that plane, will attract an external particle with a force proportional to the inverse $(n-3)$rd power of the distance from that plane. 3 Cor. Schol.

Section 14. On the motion of particles from one medium into another. (94) If a particle pass through a medium contained between parallel planes, and be in its passage attracted to or repelled from the boundary of the medium it has left with a force depending on the distance from the boundary; the sine of the angle of emergence is always in a constant ratio to that of incidence. (95) And the velocity before incidence is to that after emergence as the sine of the angle of emergence to that of incidence. (96) And if the velocity must be greater before than after incidence, the angle of incidence may be made so great that the particle shall be reflected, and the angles of incidence and reflexion are equal. Scholium. (97) To give the boundary separating two media such a form that all particles issuing from one point may be refracted to another. 2 Cor. (98) To form a lens which shall have the property mentioned in the last. Scholium.

THE SECOND BOOK, mostly on resisted motion, contains 9 sections and 53 propositions.

Section 1. When the resistance is as the velocity. (1) The motion lost is as the space described. Cor. Lemma 1. (2) When no forces act but the resistance, the velocities at the beginnings of successive equal times are in geometrical progression, and the spaces described as the velocities. Cor. (3) To determine the resisted motion of ascent or descent when the force of gravity acts. 4 Cor. (4) The same when the particle is projected obliquely. 7 Cor. and Scholium, to the effect that the hypothesis is "magis mathematica quam naturalis."

Section 2. When the resistance is in the duplicate ratio of the velocity. (5) When no force acts, equal spaces are described in times which are in increasing geometrical progression, the velocities at the beginning of the times being in the inverse geometrical progression. 5 Cor. (6) Equal and homogeneous spheres, acted on by no forces, describe equal spaces in times which are reciprocally as their initial velocities, in which also they lose the same parts of their velocities.

---

* The law of force, where not otherwise specified, is always as the inverse square of the distance.

(7) Also, in times which are as the first velocities directly and the first resistances inversely, they lose the same fractions of their velocities, and describe spaces jointly proportional to the times and the first velocities. 5 Cor. Lemma 2; which answers to finding the fluxions (called here momenta) of simple algebraical quantities. 3 Cor. and Scholium. [FLUXIONS.] (8) When a particle descends or ascends by gravity, the whole forces (gravity and resistance compounded) at the beginning of equal successive spaces, are in geometrical progression. 3 Cor. (9) Determination of the proportions of the times of ascent and descent in the last. 7 Cor. (10) The law of resistance being jointly as the density and the square of the velocity, required the law of density so that (gravity acting) a given curve may be described; as also the law of velocity. 2 Cor., followed by 4 Examp. and Schol., and also by 8 rules.

Section 3. When the resistance is partly as the velocity, partly as its square. (11) No force acting, and times being taken in arithmetical progression, the reciprocals of the velocities, increased by a certain constant quantity, will be in geometrical progression. 2 Cor. (12) But if spaces be taken in arithmetical progression, the velocities increased by a constant quantity will be in geometrical progression. 3 Cor. (13) Gravity acting, the relation between the time and velocity in the ascent or descent is shown. Cor. and Schol. (14) Relation connecting the space described with the preceding. Cor. and Schol.

Section 4. On spiral motion in a resisting medium. Lemma 3. A property of the equiangular spiral. (15) The density being inversely as the distance from the centre, and the centripetal force inversely as its square, the particle can revolve in an equiangular spiral. 9 Cor. (16) And, other things remaining, the same can be when the force is inversely as any power of the distance. 3 Cor. and Schol. (17) To find the force and law of resistance, by which a body may move in a given spiral, with a given law of velocity. (18) Given the law of force in the last, to find the density of the medium.

Section 5. On the density and compression of fluids, and on hydrostatics. Definition of a fluid. (19) A homogeneous fluid compressed in a close vessel (gravity, &c., apart) is everywhere equally pressed, and at rest. 7 Cases and Cor. (20) If a solid sphere form the nucleus of a fluid mass bounded by a concentric sphere, and the parts of the fluid gravitate equally to the centre at equal distances, the pressure sustained by the sphere is the weight of a cylinder which has the superfices for its base and the height of the incumbent fluid for its altitude. 9 Cor. (21) The density being proportional to the compression, and the centripetal force of particles inversely as their distance from the centre, then at distances in geometrical progression, the densities will be also in geometrical progression. Cor. (22) But if the force be inversely as $(\text{dist})^2$, then at distances in harmonical progression the densities will be in geometrical progression. Cor. and Schol. (23) If the particles of the fluid repel each other, the density is as the compression (and then only) when the repellent force of two particles is inversely as the distance of their centres. Scholium. (In consequence of the particles being supposed to repel only their nearest, Newton treats this only as a purely mathematical result.)

Section 6. On the resisted motion of pendulums.[*] (24) The quantity of matter in pendulums of the same length, is in a ratio compounded of their weights and of the duplicate ratio of their times of oscillation in vacuo. 7 Cor. (25) A pendulum which moves in a medium in which the resistances are as the *moments* of the times, and another moving unresisted in a medium of the same specific gravity, make their cycloidal oscillations in the same times, and describe proportional parts of their arcs together. Cor. (26) Resistance being as the velocity, cycloidal oscillations are isochronous. (27) Resistance being as the $(\text{velocity})^2$, the difference between the time of cycloidal oscillation in a resisting medium and a non-resisting one of the same specific gravity, will be very nearly as the arcs of oscillation. 2 Cor. (28) The resistances being as the moments of the time, the resistance is to the force of gravity as the excess of an arc of descent (cycloidal) over the subsequent arc of ascent to the square of the length of the pendulum. (29) Resistance being as $(\text{velocity})^2$, to find the resistance at any point of a cycloidal oscillation. 3 Cor. (30) Easier method of exhibiting the difference of an arc of descent and ascent. Cor. (31) If the resistance be altered in a given ratio, the difference of the arcs of ascent and descent is altered in the same ratio. Scholium Generale, containing many experimental results.

Section 7. On the motion of fluids and resistance of projectiles[†]. (32) Two systems of similar particles similarly placed, with given ratios between their densities, and beginning to move similarly in proportional times, will continue to do so, if there be no contact of particles except at instants of reflexion, and if there be no attracting forces of particles on one another but such as are as the diameters of corresponding particles inversely and the square of the velocities directly. 2 Cor. (33) And finite parts of these systems are resisted in a ratio compounded of the duplicate ratio of the velocities and diameters, and the ratio of the densities. 6 Cor. (34) The circular end of a cylinder encounters twice as much resistance as a sphere moving with the same velocity. Scholium, containing among other things the construction (without demonstration) of the solid of least resistance, which shows that Newton must have carried his fluxions (before 1687) far enough to solve some problems at least in what is now called the calculus of variations. (35) A medium consisting of equal particles at equal distances, to find the resistance it offers to a sphere. 7 Cor. and Schol. (36) To find the motion of water issuing through an orifice at the bottom of a cylinder. 10 Cor. Lemma 4. (37) Resistance to a cylinder moving in a non-elastic fluid. 3 Cor. and Schol. Lemma 5, 6, 7. A cylinder, sphere, or spheroid, of the same circular section, placed in a cylindrical canal of running water, or moving equally in it, is equally urged or resisted. Schol. (38) Resistance to a globe in a non-elastic fluid. 4 Cor. (39) The same when the globe is in a cylindrical canal. Schol. (40) The same, showing how to find the resistance experimentally. Scholium, containing accounts of fourteen experiments.

Section 8. On motion propagated through a fluid. (41) Pressure is not propagated through a fluid in right lines, unless when the particles lie in right lines. Cor. (42) Every motion propagated through a fluid diverges from the direct path. (43) Every tremulous body excites in an elastic medium pulses in every direction; but in a non-elastic medium, a circular motion. Cor. (44) 3 Cor. (45) Oscillation of water in a bent tube. (46) The velocity of waves. 2 Cor. (47) In pulses, the motion of the particles follow the law of an oscillating pendulum.[*] Cor. (48) The velocities of pulses in different media are as the square roots of the elastic force directly and the density inversely. 3 Cor. (49) Given the density and elasticity, to find the velocity. 2 Cor. (50) To find the length of the pulses. Scholium.

Section 9. On the circular motion of fluids. (Refutation of Des Cartes's vortices on the hypothesis that the resistance which arises from the want of *lubricity* of the parts of a fluid, is proportional to the velocity with which the parts of the fluid are separated.) (51) If a cylinder of infinite length revolve about its axis in a uniform and infinite fluid, and create a vortical motion, the periodic times of the particles of fluid are as their distances from the axis. 6 Cor. (52) But if the revolving body be a sphere, these periodic times are as the squares of the distances from the centre. 11 Cor. and Schol. (53) A body revolving in a vortex so as to return to its place, must be of the same density as the parts of the vortex, and move in the same manner. 2 Cor. and Scholium, completing the refutation above mentioned.

THE THIRD BOOK, or application, styled 'De Systemate Mundi,' contains forty-two propositions, and preliminaries. It is to be noted that it was the original intention of Newton that this book should be a popular one; and the original draft (so it is considered by Mr. Rigaud) was preserved, and was published in English, in 1728, under the title of 'The System of the World demonstrated in an Easy and Popular Manner by the illustrious Sir Isaac Newton;' and again in the original Latin. It is Opusculum XVII. in the collection of Castillioneus, who takes it from an edition published in 1731. It is not altogether popular, but, containing the mathematical propositions concerning comets to which Halley alludes in his letter, it may be the third book as it stood at the time when the idea of suppressing it was in Newton's mind. But we think that this work has been too easily admitted, and that its genuineness requires a searching discussion.

Regulæ philosophandi. 1. No more causes of natural things are to be admitted than are both true and sufficient to explain their phenomena. 2. The same causes are to be assigned to effects of the same kind, as far as that can be done. 3. Those qualities of bodies which can neither be strengthened nor weakened, and which belong to all bodies which are capable of being tried, are to be considered as universal qualities. 4. In experimental philosophy, all propositions collected by induction from phenomena are to be held either exactly or approximately true until other phenomena are found by which those propositions can be made either more accurate or subject to exception.

Phenomena. 1. The satellites of Jupiter describe areas proportional to their times about the planet, and their periodic times are in the sesquiplicate ratio of their distances from the planet. 2. The same is true of the satellites of Saturn (five then known). 3. The five primary planets, Mercury, Venus, Mars, Jupiter, and Saturn, revolve about the sun. 4. And their periodic times, and that of the earth about the sun, or the sun about the earth, the fixed stars being at rest, are in the sesquiplicate ratio of their mean distances from the sun. 5. And the primary planets are very far from describing equal areas in equal times about the earth; but do so about the sun. 6. The moon describes equal areas in equal times about the earth.

(1) The satellites of Jupiter are attracted to the planet by forces inversely as the squares of their distances. (2) The same of the primary planets about the sun. (3) The same of the moon about the earth. (4) The force which retains the moon in her orbit is the same force as that which, at the earth's surface, we call gravity. Schol. This is the celebrated test-proposition, the failure of which, in the first instance, made Newton lay his theory aside. (5) A similar result inferred as to satellites about their primaries, and primaries about the sun. 3 Cor. and Schol. (6) All bodies gravitate towards every planet; and gravitation towards every planet at a given distance from it, is as the mass of that planet. 5 Cor. (7) Attraction belongs to all

---

[*] Some of these propositions would require explanation to make their meanings clear, which we have not here room to give.

[†] See preceding note.

[*] Lagrange has shown ('Misc. Taur.') that the method of Newton here only leads to a concealed identity, which proves nothing.

bodies, and is proportional to the quantity of matter in them. 2 Cor. (8) If each of two globes be everywhere of one density at one distance from the centre, the attraction of each on the other is inversely as the square of the distance of their centres. Cor. 4. (9) In descending to the centre of a planet, gravity diminishes as the distance from that centre. (10) The motion of the planets can continue for an immensely long time.

Hypothesis 1. The centre of the solar system is at rest. (Newton takes the universally admitted hypothesis, and shows what the long disputed centre of the system is.) (11) The centre of gravity of the whole system is at rest. (12) The sun is perpetually in motion, but never far from the centre of gravity of the whole. Cor. (13) The planets move in ellipses, having their focus in the sun's centre, and they describe equal areas in equal times about that focus. (14) The nodes and aphelia of the planets are at rest: 2 Cor. and Schol. modifying the proposition by considerations of perturbation. (15) To find the axes of the orbits. (16) To find the eccentricities and aphelia. (17) The diurnal motion of the planets is uniform, and the libration of the moon arises from the diurnal motion. (18) The figures of the planets are oblate. (19) To find the proportions of the axis of a planet. (20) To compare the weights of bodies at different parts of the earth. (21) The equinoctial points must regress, and the axis of the earth must have a nutation twice in each year. (22) All the lunar motions and inequalities follow from the preceding principles. (23) The inequalities of other satellites may be derived from those of the moon. (24) The tides of the sea arise from the actions of the sun and moon. (The Jesuits' edition inserts in this place the treatises of Daniel Bernoulli, Maclaurin, and Euler, on the tides.) (25) To find the disturbing force of the sun upon the moon. (26) To find the horary increment of the moon's area about the earth. (27) From the moon's horary motion to find its distance from the earth. 2 Cor. (28) To find the diameters of the orbit in which the moon would move, but for excentricity. (29) To find the variation of the moon. (30) To find the horary motion of the moon's nodes in a circular orbit. 2 Cor. To find the horary motion of the moon's nodes in an elliptic orbit. Cor. (32) To find the mean motion of the moon's nodes. (33) To find the true motion of the moon's nodes. Cor. (Newton, in the third edition, here adds Machin's method of finding the motion of the moon's nodes.) (34) To find the horary variation of the moon's inclination. 4 Cor. (35) To find the moon's inclination at a given time. Schol. giving an account of several other peculiarities of the lunar motions, and completing the lunar theory. (36) To find the force of the sun upon the sea. Cor. (37) The same for the moon. 10 Cor. (38) To find the figure of the moon. Cor. Lemma, 1, 2, 3. On the effect of a ring of matter at the equator, disturbed by the sun, upon the earth's rotation. *Hypothesis* 2.[*] The effect of such a ring in causing precession is the same whether the ring be fluid or solid. (39) To find the precession of the equinoxes. Lemma 4. Comets are above the moon, and in the planetary regions. 3 Cor. (40) Comets revolve in conic sections, having the sun in a focus, and describe equal areas in equal times. 4 Cor. Lemma 5. To find a curve of the parabolic kind, which shall pass through any number of given points. Cor. Lemma 6. From any given places of a comet to find its place at any intermediate time. Lemmas 7, 8, 9, 10, 11. On the parabola, preparatory to the next propositions. (41) To find the parabolic orbit of a comet, from three observations. Example, the comet of 1680, from various observations, and a long discussion of the physical characters of comets. (42) To correct the orbit of a comet; with other examples and discussions. It is to be understood that throughout this third book continual comparison with observation occurs, which it is unnecessary to repeat as to each particular case, since the purpose of the book itself is the comparison of the results of theory with observation.

The 'Scholium Generale,' at the end of the Principia, has been so often quoted, alluded to, attacked, or brought forward as Newton's final explanation of the metaphysics (if that be a proper word) of his system, that even as a matter of reference we may be justified in translating it entire. It is not found in the first edition. Two notes, as marked, are Newton's.

"The hypothesis of vortices is encumbered with many difficulties. Since a planet's radius describes areas proportional to the times, the periods of the parts of the vortex should be in the duplicate ratio of their distances from the sun. And since the planets' periods are in the sesquiplicate ratio of their distances, the periods of the parts of the vortex should also be in that ratio. Since the minor vortices about Jupiter, Saturn, &c., preserve their rotation, and swim quietly in the vortex of the sun, the periodic times of the parts of the solar vortex should be equal. The revolutions of the sun and planets about their axes, which should agree with the motions of the vortices, differ from all these proportions. The motion of comets is highly regular, follows the same laws as that of the planets, and cannot be explained by vortices. They are carried most excentrically to all parts of the heavens, which could not be unless the vortices were removed.

"Projectiles, in our atmosphere, feel only the resistance of the air; take that away, as in Boyle's vacuum, and the resistance ceases, since the light feather and the solid gold fall with the same velocity in this vacuum. And such is the case in the celestial spaces which are above the atmosphere of the earth. All bodies in those spaces must move perfectly freely; and hence the planets move perpetually, according to the laws explained, in orbits of given form and position. They will persevere in their orbits by the laws of gravity; but they could by no means originally have taken that regular orbital path by the same laws.

"The six principal planets revolve about the sun in circles concentric with the sun, in the same direction, and very nearly in the same plane. The ten moons revolve about the earth, Jupiter, and Saturn, in concentric circles, in the same direction, and very nearly in the plane of their planets' orbits. And all these regular motions have no origin in mechanical causes[*]; for the comets are freely carried in very excentric orbits, and through all parts of the heavens. By such motion comets pass freely and easily through the planetary orbits, and in their aphelia, where they move more slowly and remain longer, they are very distant from each other, and attract each other very little. This most elegant group of sun, planets, and comets can only arise from the design and government of a powerful and intelligent being. And if the fixed stars be centres of like systems, all these constructions of a similar design must be under the dominion of one being: the more since the light of the fixed stars is of the same nature as that of the sun, and all the systems give light to each other. And that the systems of the fixed stars may not fall into each other, he has placed them at immense distances from each other.

"He rules all things, not as the soul of the world, but as the lord of all things. And from his dominion, God the Ruler is often called *Παντοκράτωρ*. For God is a relative term, which refers to his servants; and deity is the rule of God, not over his own body, as those think who call him the soul of the world, but over his servants. The most high God is a being eternal, infinite, absolutely perfect; but a being however perfect, without dominion, is not God the Ruler. For we say, my God, your God, the God of Israel, the God of gods, the Ruler of rulers; but we do not say, my eternal one, your eternal one, the eternal one of Israel, the eternal one of gods; we do not say, my infinite one, or my perfect one. These appellations have no relation to servants. The word God always[†] signifies ruler; but every ruler is not God. The rule of a spiritual being makes him God, true rule a true god, the highest rule the highest god, a feigned rule a feigned god. And from the reality of his dominion it follows that the true God has life, intellect, and power; and from his other perfections, that he is the highest or most perfect being. The Eternal is infinite, omnipotent, and omniscient; that is, endures from eternity to eternity, and is present from infinity to infinity; he rules all and knows all that is or can be. He is not eternity nor infinity, but eternal and infinite; he is not time nor space, but endures and is present. He endures for ever, and is everywhere present; and by his universal existence, both in time and space, he is the creator[‡] of time and space. Since any particle of space always is, and also some one indivisible moment of duration, certainly the framer and ruler of all things can never be nonexistent at any time or in any place. Every thinking soul is, at different times, and in its different organs of sense or motion, the same indivisible person. There are parts of time successive, and parts of space co-existing; but neither in the person of man, that is, in his thinking principle, and much less in the thinking substance of God. Every man, considered as a sentient existence, is one and the same man throughout his whole life, and in every one of his organs of perception. God is one and the same God always and everywhere. He is omnipresent, not only virtually but substantially; for the first without the second cannot be. In him[§] all things are contained and moved, but without mutual effect from each other. God no way feels the motion of bodies: they feel no resistance from the omnipresence of God. All men confess that the most high God exists necessarily, and by the same necessity always and everywhere. Whence also he is throughout alike, all eye, all ear, all brain, all arm, all thought, understanding and action, not in the human or corporeal manner, but in one altogether unknown. As a blind man has no idea of colour, so we have no idea of the modes in which the all-wise God perceives and understands all things. He is altogether without body or figure, and thence can neither be seen, heard, touched, nor worshipped under the likeness of any corporeal thing. We have ideas of his attributes, but we know nothing of the substance of any thing. We see only the figures and colours of bodies, we hear only sounds, we touch only external surface, we smell only odours, and taste tastes: we can perceive the inmost substance by no sense, by no reflected action; much less can we have an idea of the substance of God. Him we know only by his properties and attributes, and by the most wise and excellent structure and final causes of things; and we wonder at him for his perfections, but we venerate and worship him for his dominion. We worship him as servants, and a God without dominion, providence, and final causes is nothing else but fate and nature. From a blind metaphysical necessity, which is certainly the same always and everywhere, no variation of things can arise. Every diversity of created things in space and in time can only arise from the ideas and the will of a necessarily existing being. But God is said allegorically to see, hear, speak, laugh, love, hate, desire, give, receive, rejoice, be made angry, fight, work, build, and construct. For every expression concerning God is drawn from human affairs by a certain figure of similitude, not perfect indeed, but something like. And this much of God, of whom it certainly belongs to natural philosophy to treat from phenomena.

---

[*] In the first edition this is a lemma, which probably appeared to Newton to need no proof, as none is given. In the third it is, as we see, made an assumption. Laplace has confirmed it, by showing that the precession and nutation would remain unaltered, if the whole sea were at any one moment to be solidified without alteration of its specific gravity.

[*] By *causa mechanica* Newton means a material machinery, such as the solid orbs of some of the Ptolemaists.

[†] "Our countryman Pocock derives the word Deus from the Arabic *du* (sometimes *di*), which means ruler. And in this sense the princes are called gods, Psalms, lxxxiv. 6, and John x. 45. And Moses is called God of his brother Aaron, and of king Pharaoh, Exodus iv. 16, and vii. 1. And in the same sense the souls of departed princes were called gods by Gentile nations, but falsely from want of dominion." (Author's note.)

[‡] "Et existendo semper et ubique durationem et spatium *constituit.*"

[§] "So thought the ancients, as Pythagoras (Cic., 'De Nat. Deor.,' lib. i.); Thales; Anaxagoras; Virgil ('Georgics,' iv. 220, 'Æn.,' vi. 721); Philo ('Allegor.,' lib. i. sub init.); Aratus ('Phœn.,' sub init.). So also the sacred writers, as Paul, Acts xvii. 27, 28; John, Gospel, xiv. 2; Moses, Deut. iv. 39, and x. 4; David, Psalms, cxxxix. 7, 8, 9; Solomon, 1 King viii. 27; Job, xxii. 12, 13, 14, Jeremiah, xxiii. 23, 24. The idolators falsely imagined the sun, moon, and stars, the souls of men, and other parts of the universe to be parts of the most high God, and therefore to be worshipped." (Author's note.)

"So far I have explained the phenomena of our heavens and the sea by the force of gravity: but I have not yet assigned the cause of gravity. Certainly this force arises from some cause, which penetrates even to the centre of the sun and planets, without diminution of its virtue; and which acts not according to the superficial magnitude of particles (as do many mechanical causes), but according to the quantity of solid matter; and of which the action is extended in every direction to immense distances, diminishing always in the duplicate ratio of the distances. Gravity towards the sun is compounded of the gravity towards all the several particles of the sun, and in receding from the sun diminishes accurately in the duplicate ratio of the distances, as far as the orbit of Saturn, as is made manifest by the quiescence of the aphelia of the planets, and even as far as the aphelia of the comets, if they also do not move. But I have not yet been able to deduce the reason of these properties of gravity from phenomena, and I do not frame hypotheses. For whatever is not deduced from phenomena, is to be called *hypothesis*: and hypotheses, whether metaphysical or physical, or of occult qualities, or mechanical, have no place in *experimental philosophy*. In this philosophy propositions are deduced from phenomena, and are rendered general by induction. So impenetrability, mobility, the impetus of bodies, and the laws of motion and gravity have become known. And it is enough that gravity really exists and acts according to laws explained by me, and suffices for all the motions of the heavenly bodies and of our sea.

"I might add something on that most subtile spirit which pervades solid bodies and lies hidden in them, by the force and action of which the particles of bodies attract each other at the smallest distances, and adhere when contiguous: and by which electric bodies act at greater distances, both by attracting and repelling neighbouring particles; and by which light is emitted, reflected, refracted, inflected, and gives heat to bodies; and by which all sensation is excited, and the limbs of animals are moved at pleasure, namely, by its vibrations through the solid capillaments of the nerves, propagated from the external organs of sense to the brain, and from the brain to the muscles. But this could not be explained in few words; nor is there a sufficient quantity of experiments to show and determine the laws according to which this *spiritus* acts."

There is not a sentence of the preceding scholium which has not a direct reference to some common opinion, at home or abroad, of the physics, metaphysics, or theology of Newton's system. He had probably seen and heard enough, in the interval between the editions, to teach him on what points explanation was desirable; certain it is, that there is hardly an objector since his time who might not have found himself already answered, if he had read this scholium with candour and attention.

The commentators of Newton have one and all, as might be supposed, treated their author as a source of elementary instruction, to be explained and cleared from the effects of that brevity and obscurity (the latter more than due to the former) which the Principia almost everywhere presents. But the time has arrived when this work is hardly in the beginner's course, though it may be recommended to him, when he has studied the modern analysis, to make himself acquainted with its methods until he has caught their spirit. What we now want is rather an historical commentary, which shall put the student in possession of the modes of reasoning peculiar to Newton's predecessors, shall point out how the Principia came to have its form, and shall place him, so far as is possible, in the midst of that atmosphere of remnants of the old philosophy and aspirations after the new, in which the mind of Newton gained its growth.

In 1730, Dr. John Clarke published 'A Demonstration of some of the principal sections of Sir I. Newton's Principles,' &c. This work contains the greater part of the first book somewhat expanded, and with the applications of the third book intermixed. But it omits the most important part of the eleventh section: nevertheless, a student who should join with Dr. Clarke's work the article GRAVITATION in the present one, would have the most important parts of the Principia, so far as is necessary to gain an insight into Newton's methods.

In the same year, 1730, George Peter Domck published his 'Philos. Math. Newt. Illustratæ Tomi Duo, Londini.' (This work is sometimes wrongly called an edition of the Principia, and its author's name is sometimes spelled Donick.) The first volume of it is only a preparatory course of mathematics; the second gives a large part of the first book in Newton's manner, and gives more of the results of the eleventh section. It also enters upon some of the numerical applications of the third book.

The Commentary of the Minims (Jesuits they are usually but wrongly called) Le Sueur and Jacquier (1739) is an excellent performance for its time, considered as attempting to smooth the details of the mathematical difficulties. It uses algebra freely, but is totally insufficient to show the use of the differential calculus as now known; but it very frequently developes satisfactorily a point at which Newton only hinted.

Emerson's 'Short Comment on Newton's Principia,' 1770, is a brief explanation of some of the mathematical difficulties and obscurities, followed by defences of the Principia, the Optics, and the Chronology. Emerson defended everything of Newton's.

The popular explanations of Maclaurin, Pemberton, and Voltaire are too widely known to need description; they do not much help the mathematical student. Many so-called explanations of Newtonian philosophy (such as Benjamin Martin's, 1751) are literally nothing but treatises on general physics.

The additions to Madame du Chastellet's translation consist of a popular *résumé* and the mathematical treatment of various questions of the Principia. The latter must be considered as emanating from Clairaut, since they were his lessons to his pupil. Some have supposed that Voltaire's work belongs in the same sense to Madame du Chastellet.

In the 'Mécanique Céleste,' book 16, cap. 2, Laplace has exhibited the results of Newton's lunar theory, and connected them with the modern analysis of the subject to a certain extent. The preciseness of the manner of compressing Newton's results renders this chapter valuable, and likely to assist the student of the Principia.

Mr. Airy's development and extension of the results of the eleventh section (which forms the article GRAVITATION in this work) places one of the methods of the Principia, and one which ought to last, within the reach of every student. It is unique, the difficulties of the eleventh section having left it almost without a commentator, and altogether without an explainer; and it takes in several of the discoveries of the present time.

Many commentaries on the Principia have been written at Cambridge by private tutors for the use of their pupils, of which some have been printed. Of the following we have never seen more than the title: 'Excerpta quadam e Princ. Phil. Nat., cum notis variorum,' Cambridge, 1765. There is Carr's three sections of Newton, a modern work, and an exposition of various parts of the Principia contained in the second edition of Professor Whewell's 'Dynamics.' We believe that several recent Cambridge works contain some help on the subject.

To give a view of the foreign objections to Newton's system, at the time of its first introduction, the following works may serve: 1, 'Collection of Papers which passed between Mr. Leibnitz and Dr. Clarke, in 1715 and 1716,' by Dr. Samuel Clarke; London, 1717. 2, 'Traité de Paix entre Des Cartes et Newton,' by the Jesuit Aimé-Henri-Paulian; Avignon, 1763. 3, 'Le vrai Système de Physique générale de M. Isaac Newton, exposé et analysé en parallele avec celui de Des Cartes,' by the Jesuit Louis Castel; Paris, 1743 (a defence of Descartes). 4, 'Anti-Newtonianismus,' by Celestini Cominale, M.D.; Naples, 1754. 5, 'Discours sur les différentes Figures des Astres,' by Maupertuis, the first assertor of Newton's doctrines in France; Paris, 1732, and in the collection of his works. 6, 'Letters to a German Princess,' by Euler (first published in 1770, translated into English by Dr. H. Hunter, 1795).

The most celebrated comments in the way of objection are those of LEIBNITZ, JOHN BERNOULLI, and HUYGHENS [see BIOG. DIV.]; the first and third real admirers of the genius of Newton, the second also an admirer after his fashion. Many of their remarks may be found in the published correspondence of the first two, but the history of the effect produced by the Principia in the years following its publication is scattered in too many places for us to attempt to give the particular publications which should be consulted.

PRINCIPLE, D'ALEMBERT'S. [FORCES, IMPRESSED AND EFFECTIVE; VIRTUAL VELOCITIES.]
